Report of the Meeting

Introduction

1. In accordance with the United Nations Environment Programme/Mediterranean Action Plan (UNEP/MAP), Programme of Work 2020-2021 adopted by the 21st Ordinary Meeting of the Contracting Parties to the Barcelona Convention and its Protocols (Napoli, Italy, 2-5 December 2019), the UNEP/MAP Secretariat organized the MED POL Focal Points Meeting via videoconference in two parts: Part I convened with an initial session on 27-28 May and a resumed session on 9 July 2021. Part II of the meeting was held on 6-7 October 2021. The 5-day duration of this two-part meeting was deemed to be required to address all agenda items for its smooth running.

2. The objective of the MED POL Focal Points Meeting was to review the progress on the implementation of PoW activities carried out during the 2020-2021 biennium, and the status of implementation of the pollution-related Protocols of the Barcelona Convention including its monitoring and assessment aspects which are under the MED POL Programme responsibility. This includes the updated annexes of the LBS and Dumping Protocols; the three Regional Plans for Wastewater Treatment, Sewage Sludge Management and the Updated Marine Litter Management Plan; the Mid-Term evaluation of the Implementation of the National Action Plans; implementation of IMAP for Pollution and Litter cluster including harmonization and standardization of IMAP pollution cluster monitoring, and cross-cutting issues related to integration and aggregation rules for IMAP Ecological Objectives 5, 9 and 10, as well as assessment criteria for contaminants, nutrients and marine litter. The Meeting is also planned to review several technical guidelines to support the sound marine pollution assessment of levels and loads addressing both LBS and Dumping Protocols-related activities.

3. Part I of the MED POL Focal Points Meeting, including the initial session on 27 and 28 May and the resumed session on 9 July, cover agenda items which will be submitted to the MAP Focal Points and ECAP Coordination Group Meetings. Part II of the meeting held on 6 and 7 October 2021 addresses all remaining agenda items.

Participation

4. The Meeting was attended by representatives from the following Contracting Parties: Albania, Algeria, Bosnia and Herzegovina, Croatia, Cyprus, Egypt, European Union, France, Greece, Israel,[1] Italy, Lebanon, Libya, Malta, Monaco, Montenegro, Morocco, Slovenia, Spain, Tunisia and Turkey. The United Nations Environment Programme (UNEP), including the Mediterranean Action Plan/ Barcelona Convention Secretariat (UNEP/MAP) were also represented, along with the following Mediterranean Action Plan Components: the Mediterranean Pollution Assessment and Control Programme (MED POL); the Specially Protected Areas Regionally Activity Center (SPA/RAC); the Regional Activity Centre for Sustainable Consumption and Production (SCP/RAC); and Plan Bleu Regional Activity Centre. The Meeting was also attended by the Secretariat of the Basel, Rotterdam and Stockholm Conventions (BRS); the Regional Organization for Conservation of the Environment of the Red Sea & Gulf of Aden (PERSGA); the International Maritime Organization (IMO); the International Atomic Energy Commission (IAEA); the Economic and Social Commission for Western Asia (ESCWA); UNEP Regional Office for Western Asia (UNEP/ROWA); the Secretariat of the Pacific Regional Environment Programme (SPREP); and the European Environment Agency (EEA).

5. The following non-governmental organizations and other institutions were represented: the Hellenic Centre for Marine Research/ Institute of Oceanography (HCMR); the Mediterranean Information office for Environment, Culture and Sustainable Development (MIO-ECSDE); the

[1] Israel was not present in the resumed session on 9th of July 2021

International Union for Conservation of Nature (IUCN); PlasticsEurope; the World Wide Fund For Nature (WWF Mediterranean); the Hellenic Marine Environment Protection Association (HELMEPA); the Centre International de Droit Comparé de l'Environnement (CIDCE); the Egyptian Sustainable Development Forum (ESDF); the Egyptian Youth Ambassadors; Grid-Arendal; and the "association de la continuité des générations" (ACG).

6. The full list of participants is attached as Annex I to the present report.

Agenda item 1: Opening of the Meeting

7. The initial session of the meeting was opened at 10:00 AM (EST) on 27 May 2021 by the Deputy Coordinator of the United Nations Environment Programme/ Mediterranean Action Plan - Barcelona Convention, Ms. Tatjana Hema. She provided a summary overview of work undertaken by MED POL in the biennium 2021-2022; explaining the importance of externally funded projects that are based on, and complement, activities in the Programme of Work for this biennium. She stressed the support provided to the Contracting Parties including technical meetings convened and related documents produced, explaining at the same time the institutional and decision-making process of relevance to the Meeting for approval of these documents. She provided information on the decisions under preparation by MED POL, noting the updated annexes to the LBS and Dumping Protocols and the three Regional Plans, planned for submission to COP 2 2for adoption. Mr. Mohamad Kayyal, MED POL Programme Management Officer, gave a brief overview of the documents to be discussed under each agenda item, and introduced the MED POL team who will deliver the presentations of each of these documents.

8. The resumed session of Part I of the Meeting convened on 9 July at 10:00 AM. It was opened by the Chair of the Meeting, Ms. Marta Martinez-Gil Pardo de Vera. She gave a brief recap of decisions reached in the initial session. She also highlighted the remaining agenda items to be addressed during the resumed session. The MED POL Programme Management Officer provided an overview of remaining documents to be discussed during this resumed session and related agenda items.

9. Part II of the meeting convened on 6 and 7 October at 10:00 AM. The Meeting was opened by the Chair, Ms. Marta Martinez-Gil Pardo de Vera. She presented an overview of remaining agenda items not covered in Part I of the meeting. The MED POL Programme Management Officer explained the scope of documents to be addressed focusing on the monitoring guidelines/protocols for IMAP Common Indicators; the common methodologies on estimation techniques for the National Baseline Budget (NBB) of pollutants; assessments for the preparation of three new regional plans for the biennium 2022-2023; and methodologies and techniques for the assessment and monitoring of adverse impacts of dumping activities.

Agenda item 2: Election of Officers

a) Election of Officers

10. Subject to Rule 20 of the rules of procedure mentioned at para. 2(a) for meetings and conferences of the Contracting Parties, the Meeting elected one (1) President, three (3) Vice Presidents and one (1) Rapporteur from among the participants, as follows:

Chair:	Ms. Marta Martinez-Gil Pardo de Vera, Spain
Vice-Chair:	Mr. Mohamed Elbouch, Morocco
Vice-Chair:	Mr. Konstantinos Antoniadis, Cyprus
Vice-Chair:	Ms. Klodiana Marika, Albania
Rapporteur:	Ms. Marwa El Mokdad, Lebanon

Agenda item 3: Organizational matters and adoption of the agenda

a) Rules of Procedure for the Meeting

11. The Rules of Procedure for Meetings and Conferences of the Contracting Parties to the Convention for the Protection of the Marine Environment and the Coastal Region of the Mediterranean and its Protocols was applied mutatis mutandis to the present meeting (UNEP/IG.43/6, Annex XI).

b) Adoption of the Provisional Agenda

12. Subject to Rule 14 of the Rules of Procedure mentioned at para. 2(a), the proposed agenda appearing in document UNEP/MED WG.509/1 and annotated in document UNEP/MED WG.509/2 was reviewed during the initial session on 27 May 2021. Turkey raised observation to Working Document UNEP/MED WG.509/10 and Information Document UNEP/MED WG.509/Inf.14 requesting their withdrawal from the list of documents of the meeting. The Meeting requested clarifications regarding the issues of concern in both documents. Turkey pointed out to the issue of certain maps which contain information to which they do object, in addition to the use of some terms and reference material. Further to this clarification, the Meeting agreed for the Secretariat to amend working document UNEP/MED WG.509/10; withdraw information document UNEP/MED WG.509/Inf.14 from the list of documents; and prepare an updated list of documents and revised annotated agenda. The Secretariat distributed the aforementioned documents in the same session after the first break. The Meeting adopted the revised annotated agenda as appended in Annex II to the present document.

13. During the resumed session on 9 July, a Contracting Party requested clarifications on the reason why document UNEP/MED WG.509/Inf.14 was withdrawn in the initial session. The Coordinator taking the floor recalled the discussion held during the first session of the meeting noting that this decision was taken during the adoption of the agenda. The Coordinator also acknowledged that the report of the meeting will provide information on this issue. The Chair reiterated also that this decision was made in the initial session on 27 May to withdraw document UNEP/MED WG.509/Inf.14 from the list of documents.

c) Organization of Work

14. The discussions were held in plenary sessions for the entire meeting. Three sessions were planned daily from 10:00 to 12:00, 13:00 to 15:00, and 15:30-17:30, with two mid-day breaks.

15. Simultaneous interpretation in English and French was available for all sessions. All documentation was available in English and French. Participants were encouraged to download the documentation onto their computers in advance of the session. The meeting was recorded for future reference.

16. The Meeting addressed in the “initial session” of Part I of the Meeting on 27 and 28 May agenda items: 1, 2, 3, 5, 6 as well as 9 as detailed in Annex II. For the “resumed session” on 9 July, the Meeting covered agenda items 7 and 8 followed by agenda item 4. During Part II of the Meeting on 6 and 7 October, remaining agenda items 12 through 15 were discussed.

17. At the end of each session of Part I and Part II of the meeting, the meeting addressed agenda items “any other business” and the agenda items “conclusions and recommendations”, respectively.

18. Conclusions and recommendations of the MED POL Focal Points Meeting as adopted are appended in Annex III to this document.

Agenda item 4: Progress achieved regarding implementation of the Programme of Work 2020-2021 related to Land-Based Pollution and Governance Themes

19. Agenda item 4 was discussed in the resumed session on 9 July 2021. Under this agenda item, the Secretariat presented document UNEP/MED WG.509/3 "Progress Achieved regarding the Implementation of the Programme of Work 2020-2021 related to Land Based Pollution and Governance Themes." Presentation provided key highlights to work undertaken for preparation of the three Regional Plans on Urban Wastewater, Sewage Sludge and Marine Litter, as well as the assessment of implementation costs and socioeconomic benefits, and the three assessments of current practices in the agriculture and aquaculture sectors, as well as urban storm water management as background documents for preparation of related Regional Plans in biennium 2022-2023.

20. The Secretariat also presented work undertaken to update the annexes of the LBS and Dumping Protocols, and the indicator-based midterm evaluation of the implementation of National Action Plans (NAPs) 2015-2020, as well as an overview of technical guidelines aiming to complement the NBB/PRTR Methodology for 5th Cycle of NBB. Highlights were also provided for two complementary documents on "Compendium of Best Practices on Implementation of Dumping Protocol," and Common methodologies and techniques for the assessment and monitoring of adverse impacts of dumping activities.

21. The Secretariat gave a brief overview of efforts undertaken for ensuring coordinated implementation of IMAP Pollution and Marine Litter Cluster on regional and national levels; work progress for reinforcing the generation and reporting of new quality-assured national monitoring data to IMAP Info System including interlaboratory comparison and assessment of the capacities of national laboratories and monitoring guidelines/protocols for IMAP Common Indicators 13, 14, 17, 18, 20 and 23; as well as progress achieved towards GES thematic assessment products for EOs 5, 9 and 10.

22. Finally, the Secretariat provided an overview of coordination efforts and joint activities with other regional and global organizations as well as participation in meetings and working groups; contribution to implementation of externally funded projects including the GEF funded "Mediterranean Sea Programme (MedProgramme); and EU-funded projects IMAP-MPA, EcAp-MED III and Marine Litter MED II.

23. The Meeting congratulated the Secretariat on progress made for implementation of the Programme of Work. The Meeting acknowledged the work undertaken by MED POL and achievements made during the biennium 2020-2021, particularly with regards to the development/updating of the Regional Plans, updating of the annexes of the LBS and Dumping Protocols, as well as work under IMAP Pollution and Marine Litter Cluster.

24. The Meeting's final conclusions related to this agenda item are presented in Annex III of this report.

Agenda item 5(a): Update of the Annexes of the Land-Based Sources (LBS) Protocol

25. Agenda item 5(a) was presented in the initial session on 27 May 2021. Under this agenda item, the Deputy Coordinator presented document UNEP/MED WG.509/4 "Proposals for Updating the Annexes to the LBS Protocol" to the Meeting for their consideration and review. She explained the amendments agreed during the Working Group Meeting of the Designated Experts (10 December 2020), including proposals for taking into account the Ecosystem Approach with the aim to achieve and/or maintain Good Environmental Status (GES), as well as other global and regional developments under the Stockholm Convention; the Marine Strategy Framework Directive; and the Pollution Release and Transfer Register (PRTR). She underlined the work undertaken with SCP/RAC which included additions on the subjects of circular economy approaches in production processes taking into

account the scope of the application of the LBS Protocol as well as further elaborations of BAT and BEP definitions.

26. The Contracting Parties acknowledged the importance of the additional sources of pollution which have potential impairment to marine ecosystem such as noise, artificial light and others which were updated in Annex II. The participants discussed and agreed on the definitions of BAT and BEP proposed by the Deputy Coordinator; also pointing out the importance of incorporating the concepts of eco-design and eco-innovation into Annex IV. The meeting participants concurred with the proposed amendments and agreed to submit the Annexes of the LBS Protocol to the MAP Focal Points.

27. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 5(b): Update of the Annex of the Protocol for the Prevention and Elimination of Pollution of the Mediterranean Sea by Dumping from Ships and Aircraft or Incineration at Sea

28. Agenda item 5(b) was presented in the initial session on 27 May 2021. Under this agenda item, the Deputy Coordinator presented document UNEP/MED WG.509/5 "Proposals for Updating the Annex to the Dumping Protocol" to the Meeting for their consideration and review. She explained the amendments considered and agreed during the Working Group Meeting of Designated Experts (09 February 2021), which are based on the 1996 London Dumping Protocol and related developments under the Marine Strategy Framework Directive (MSFD), as well as application of the ecosystem approach.

29. The Contracting Parties took note of work done and concurred with the proposed amendments by the Deputy Coordinator. No further technical comments were proposed. The meeting participants approved the amendments to update the "Annex of the Protocol for the Prevention and Elimination of Pollution of the Mediterranean Sea by Dumping from Ships and Aircraft or Incineration at Sea" and recommended submission to the MAP Focal Points.

30. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 6(a): Review of the Regional Plan on Urban Wastewater Treatment

31. Agenda item 6(a) was presented in the initial session on 27 May 2021. Under this agenda item, the Deputy Coordinator presented document UNEP/MED WG.509/6 "Regional Plan on Urban Wastewater Treatment." During her presentation, she highlighted progress made during the second working group meeting held back-to-back with this MED POL Focal Points Meeting. She emphasized issues pending which were placed in brackets to be resolved during this meeting. She indicated that the aim of discussions is to approve the Regional Plan for submission to the MAP Focal Points.

32. Concerning Article 1 (Definition of Terms), one meeting participant raised a point regarding the need to use composite samples for measuring ELVs. The Deputy Coordinator indicated that the use of these samples is not conditional. The meeting participants agreed to delete this reference clause.

33. With regards to Article V (Measures) which covers four principal topics: (i) collection and treatment of urban wastewater, (ii) reclamation and reuse of wastewater, (iii) industrial wastewater discharge; and (iv) monitoring, and further to the Deputy Coordinator's overview of proposed updates:

a. Further to postponing discussions to the MED POL Focal Points Meeting by the 2nd Working Group regarding the deadline dates of 2025 and 2035 for providing agglomerations with collecting systems for urban wastewater, the Contracting Parties did not concur on the proposed dates either, pointing to the political implications of this

decision. Israel inquired about the underlying reasons for justifying these dates, proposing also the date of 2030.The Meeting requested to postpone decision on the deadline dates for the consideration of the MAP Focal Points Meeting in September 2021.

b. Further to unsuccessful discussions by the Meeting of the 2nd Working Group to agree on the date for adoption of the emission limit values and its proposal to postpone discussions to the MED POL Focal Points Meeting, the Contracting Parties did not concur on the proposed date either. A number of Contracting Parties raised some concerns indicating that 2023 is too early a date to meet. At the conclusion of discussions, the Meeting requested to postpone decision on the proposed date for the consideration of the MAP Focal Points Meeting.

c. Further to the request of the Meeting of the 2nd Working Group, the Deputy Coordinator presented its proposal for alternative limit values for BOD, total nitrogen, arsenic, residual chlorine, COD, pH, phenol and total hydrocarbons as part of the emission limit values included in Appendix I.A (the 2nd Working Group Meeting agreed to the remaining ELVs in Appendix I.A). The Contracting Parties agreed to the proposed alternative values including 0.5 mg/l for Copper requested by Malta. A number of Contracting Parties enquired about the nature and scope of a risk-based assessment which was specified as a footnote in the Appendix. The Deputy Coordinator indicated that this aspect will be addressed in the technical guidelines currently under preparation to assist in the implementation of the Regional Plan.

d. The Contracting Parties agreed with the alternative emission limit values for reuse of reclaimed wastewater for agriculture (Appendix I.B) as proposed by the Deputy Coordinator further to the request of the Meeting of the 2nd Working Group.

e. Concerning emission limit values for discharge of industrial wastewater into collecting systems and WWTPs as stipulated in Appendix I.C, Israel enquired about limit ratio of COD to BOD. The Deputy Coordinator explained that the upper limit for COD to BOD ratio would ensure that no chemical treatment is needed. Turkey sought clarifications about applicability of ELVs to small industries, particularly with regards to heavy metals. The Deputy Coordinator indicated that the Contracting Parties may increase the ELVs for small industries discharging to the collecting system when (i) the plant uses BAT; and (ii) the effects of the discharged effluent on the collecting system and the WWTP are negligible. This justification was appended to the first footnote of Table 3 in Appendix I.C. The Contracting Parties agreed with the proposed ELVs.

f. In line with the request of the Meeting of the 2nd Working Group to consider the dates of 2030 and 2035 for ensuring that wastewater discharges meet adopted ELVs, the Contracting Parties did not concur/agree on the proposed dates. Italy, Spain, Malta and France raised a “study reservation” on the two clauses dealing with discharges from agglomerations between 2000 and 15,000 p.e. and over 15,000 p.e. indicating that a formal response will be sent to the Secretariat for further consideration and discussion during the MAP Focal Points Meeting.

g. Reference to the request of the 2nd Working Group Meeting to discuss the deadline dates of 2025 for adopting emission limit values by competent authorities for industrial wastewater and 2035 for implementing the adopted ELVs for discharges to collecting systems and urban wastewater treatment plants by the MED POL Focal Points Meeting, the Contracting Parties did not reach consensus on both issues either. The Meeting proposed postponing discussions on these deadline dates for the consideration of the MAP Focal Points Meeting.

34. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 6(b): Review of the Regional Plan on Sewage Sludge Management

35. Agenda item 6(b) was presented in the initial session on 27-28 May 2021. Under this agenda item, the Deputy Coordinator presented document UNEP/MED WG.509/7 "Regional Plan on Sewage Sludge Management" which was updated further to comments provided by the 2nd Working Group Meeting for their consideration and review. She described proposals made which are incorporated in this updated version. She emphasized remaining issues placed in brackets by the 2nd Working Group Meeting that need to be addressed by the MED POL Focal Points Meeting. She indicated that the aim of discussions is to approve the Regional Plan for submission to the MAP Focal Points.

36. Concerning Article V (Measures), and with regard to:
    a. Treatment of sewage sludge: the Focal Points agreed to add "cement industry" sector to the list of specific uses of treated sludge.
    b. The Focal Points concurred on introducing two Classes (A and B) for land application of sludge for agricultural use. The Focal Points further agreed on a legally binding date of 2025 for setting Class 'A' sewage sludge with limit values for pathogen contents for biosolids as indicated in Table 1 of the Regional Plan. Regarding Class 'B', the Focal Points agreed to set this Class with specifications as per Table 1, where appropriate.
    c. Italy requested that the specifications for Faecal Coliforms be expanded to include also Escherichia coli. Taking into consideration the "EU regulation 2019/1009 of 5 June 2019 laying down rules on the making available on the market of EU fertilising products," the Deputy Coordinator proposed the requested ELVs for Escherichia coli with a limit value of 1000 MPN/g DM for Class A and 200,000 MPN/g DM for Class B. The Focal Points agreed to both limit values, which were added in parentheses in Table 1. In this regard, Turkey noted that only Class B sludge is regulated in Turkey which meets the ELV for Faecal Coliforms of 2,000,000 MPN/g DM (similar to the Regional Plan); however, use of Class B sludge includes, in addition to prescribed uses in the Regional Plan, production of fruit trees and vegetables whose fruit or leaves do not touch the ground. Turkey requested additional time to discuss the matter further with national experts before reverting back to the Secretariat with its response. Accordingly, the requirement for adoption of Classes A and B, including the proposed deadline of 2025, is placed in square brackets for the consideration of the Meeting of the MAP Focal Points in September 2021.
    d. Regarding ELVs for concentrations of heavy metals in biosolids and soil (Tables 2 and 3), and further to postponing decision by the 2nd Working Group, the Focal Points agreed to set a legally binding date for adopting these ELVs in 2025 at the latest.
    e. Further to the consideration of the 2nd Working Group, the Focal Points agreed on the "applicable measures" as well as the legally binding "deadline of 2035" for establishment of required infrastructure for sewage sludge use for agricultural land applications and/or for energy/nutrient recovery.
    f. Concerning monitoring of quality of sewage sludge, the Deputy Coordinator provided a proposal whereby the Contracting Parties shall take measures to ensure monitoring of the quality of sewage sludge in the WWTP or after treatment outside the WWTP, whereby the Contracting Parties shall select the adequate monitoring programmes as indicated in Table 4 on the frequency of monitoring. The Contracting Parties agreed with the proposed clause and corresponding Table 4.

37. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 6(c): Review of the Updated Regional Plan on Marine Litter Management in the Mediterranean

38. Agenda item 6(c) was presented in the initial session on 28 May 2021. Under this agenda item, the Deputy Coordinator introduced document UNEP/MED WG.509/8 "Updated Regional Plan on Marine Litter Management in the Mediterranean." During her presentation, the Deputy Coordinator highlighted the fact that the updates for the Regional Plan have been undertaken by GRID-Arendal, designated as an official UNEP Centre which collaborates with the United Nations Environment Programme and other partners. She updated the MED POL Focal Points on the outcome of the 2nd Working Group Meeting summarizing changes introduced and focusing on remaining issues to be resolved mainly related to marine litter prevention measures.

39. Concerning Article 3 (Definition of Terms), the Focal Points accepted the definitions proposed by the Deputy Coordinator and/or Countries as a basis for the final definitions, with some modifications for microplastics, fishing gear, extended producers' responsibility, and circular economy. One Contracting Party proposed an alternative definition for marine litter monitoring. The Focal Points agreed with this proposal. Malta proposed three additional definitions on "plastics," "lightweight plastic carrier bag" and "waste". The Deputy Coordinator indicated that it would disseminate the proposed definitions to the MED POL Focal Points, and if all respondents agree on proposed definitions with no modifications or objections within a period of 3 days, then the three definitions will be included under Article 3. All Focal Points agreed with this course of action.

40. Concerning Article 7 (Integration of Marine Litter Measures into the LBS National Action Plans), the Focal Points requested to delete the word "improve" from point (d) listed under the outline for the LBS NAPs whereby measures and targets are set to increase plastic waste collection and recycling. The Meeting concurred with this modification.

41. Regarding Article 9 (Prevention of Marine Litter), the Focal Points provided the following comments:

a. Concerning economic instruments, one Contracting Party corrected the label for "Deposits and Refund System".
b. With regard to circular economy for plastics, and further to discussions held during the 2nd Working Group Meeting, the Focal Points agreed to the date of 2025 to be applied for prevention measures aiming to achieve a circular economy for plastics. They further agreed further to discussions held during the 2nd Working Group Meeting with the proposal of the Deputy Coordinator to delete the measures requiring the need to put in place a system to identify sources of plastic litter and also to identify/phase out single-use plastic products of concern. On the other hand, the Focal Points agreed to add clauses on the consideration of the list of Single Use Plastic items presented in Annex I to the Regional Plan; identification of single-use plastic products which are most found and cause impacts on the marine environment; as well as implementing sound measures to phase out consumption and production; setting of targets to phase out production and use of nonreusable, non-recyclable, and non-compostable plastic products; and endeavoring to substitute plastics.
c. In reference to Land-based sources, and further to discussions of the 2nd Working Group, the Focal Points agreed to the proposal of the Deputy Coordinator to take into consideration the occurrence and extent of marine litter accumulations in order to assess their impacts.

42. Concerning Article 10, the Focal Points requested from the Secretariat to provide in a footnote examples for reference campaigns in relation to International Coastal Cleanup Campaigns and Programmes. However, the Focal Points did not reach agreement on the establishment by 2030 of ALDFG removal and recycling programmes, postponing discussions to the MAP Focal Points Meeting.

43. Regarding Article 16, the Focal Points agreed to add "co-responsibility of all stakeholders" to the enhancement of public awareness and education for the marine litter issue.

44. Finally, with regard to the Annex I providing the "List of Single Use Plastic (SUP) Items," and further to discussions held by the 2nd Working Group, the Focal Points agreed to include in the Regional Plan the "Mediterranean Priority List of SUPs per Group of Items" which are listed in the Regional Guidelines to tackle single use plastic products in the Mediterranean (UNEP/MAP SCP/RAC 2021). Concerning Annex II providing a "List of Chemical Additives of Concern Used in Plastic Production," the Focal Points agreed to include this annex in the Regional Plan based on the list of persistent organic pollutants (POPs) used as additives in plastics and listed in Annex A (elimination) and Annex B (restriction) to the Stockholm Convention as of 2021.

45. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 7: Indicator-based midterm evaluation of the implementation of National Action Plans/Programme of Measures (2015-2020)

46. Agenda item 7 was presented in the resumed session on 9 July 2021. Under this agenda item, the Mr. Erol Cavus, MED POL Programme Officer presented the Working Document UNEP/MED WG.509/9 "Indicator-based midterm evaluation of the implementation of National Action Plans/Programme of Measures (2015-2020)." He noted that COP19 urged the Focal Points to report on the implementation of the NAPs in the framework of Article 13 of the LBS Protocol and requested the Secretariat (MED POL Programme) to undertake in 2020 an indicator-based midterm evaluation of the NAPs' implementation based on the existing reporting system and in close collaboration with the Contracting Parties. He indicated that the midterm evaluation report was reviewed by the Meeting on "National Baseline Budget Methodologies, Assessments of new Regional Plans and Evaluation of National Action Plans under the LBS Protocol" (videoconference 22-23 April 2021) which recommended its submission, with some modifications, to the MED POL Focal Points meeting.

47. Turkey commented on information document UNEP/MED WG.509/Inf.19 "Rational and Approach for Preparing the Indicator-based midterm evaluation of the implementation of National Action Plans/Programme of Measures (2015-2020)" noting that the graphical presentation of percentage plastics is not clear. The Secretariat indicated that related information will be reviewed and clarified. The Meeting approved the document UNEP/MED WG.509/9 and recommended its submission to the Meeting of the MAP Focal Points as well as to COP 22 as "information document."

48. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 8(a): Integration and Aggregation Rules for Monitoring and Assessment of (IMAP Pollution and Marine Litter Cluster

49. Agenda item 8(a) was presented in the resumed session on 9 July 2021. Under this agenda item, Ms. Jelena Knezevic, MEDPOL Monitoring and Assessment Officer, presented the Working document UNEP/MED WG.509/10/rev.2 "Integration and Aggregation Rules for Monitoring and Assessment of IMAP Pollution and Marine Litter Cluster." She explained the proposals elaborated in this document with regards to strengthening IMAP Pollution and Marine Litter implementation at national level; integration and aggregation rules for monitoring and assessment for IMAP Pollution and Marine Liter Cluster; elaboration of the scales of assessment by proposing upgraded aggregation scheme for the areas of assessment for EOs 5, 9 and 10 within the nested approach; and the rules for integration of assessments within the nested approach for IMAP Pollution and Marine Litter Cluster. She also presented the results of different case studies regarding testing of the NEAT tool application in order to explain its possible application for GES assessment of Ecological Objectives of IMAP Pollution Cluster. She also provided an explanation regarding the changes undertaken in line with

comments and conclusions of the Meeting of the CorMon on Pollution Monitoring. The Secretariat also explained that the revised document contains a disclaim as well as some adjustment to the terms used throughout the document in order to avoid any possible confusion.

50. Following the opening of the discussion by the Chair, Turkey provided specific comments. These included identifying countries for which monitoring efforts under IMAP are extended to offshore areas (Para 11) and deleting the "geographical scale" (Para 19). Turkey also proposed an adjustment to the disclaimer proposed by the Secretariat. It also commented on the need to consider assessment areas defined by the Contracting Parting within implementation of MSFD (Para 22); deleting reference to "nested" scales approach (Para 23); removing "natura sites" from the GIS based layers (Para 25 as well as Table 6); deleting criteria (v) related to taking into account administrative boundaries of the Contracting Parties (Para 27); deleting the term "small areas" (Para 33); replacing national parts with Countries (Para 38); simplifying Paragraph 39; using the term "particular assessment area" and not "MRU" (Para 42); explaining the meaning of GES Decision Rule in Paragraph 45 as well as deleting the following "recommended by the EU MSFD (SWD (2020) 62 final)"; adding to the list of abbreviations the acronyms "ECs" and "ERL" (Para 49); and deleting the sentence "NEAT was firstly developed to assess biodiversity status of marine waters under the MSFD and since then has been used to assess different ecosystem components and geographical areas" (Para 53).

51. Following the discussion, there were a number of disagreements by some Contracting Parties on the points raised. Further to these comments the Chair recommended to capture the reservations of Turkey for consideration by the Secretariat at a later stage. The MAP Legal Officer confirmed that the disclaimer as amended by Turkey is correct from a legal perspective. The Coordinator indicated that the Secretariat would verify the content of the amended disclaimer with the UNEP Headquarter

52. Following the discussions, the Coordinator indicated the need to adhere to the scope of the Barcelona Convention, noting that IMAP is providing new challenges that we were not fully prepared for, and there is a need to learn how to handle them all together. The Coordinator further clarified that this is an evolving document. She also recommended testing of the proposed methodology on national or regional level so we can assess if there is a need for adjustment. Once the methodology is validated, it will be introduced for use in the 2023 MED-QSR. The Coordinator following a valid proposal by a Contracting Party enquired whether it would be more appropriate for this document to be sent to the CorMon for review in order to also allow time for the three other remaining documents under this agenda item for this session of the MED POL Focal Points Meeting Part I to be addressed.

53. Several interventions were made by a number of Contracting Parties on whether the document should be reviewed by the CorMon or go to the EcAp Coordination Group Meeting for its consideration. The Meeting finally agreed to send the document back for the consideration of the CorMon.

54. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 8(b): Updated Baseline Values and Proposal for Threshold Values for IMAP Common Indicator 22

55. Agenda item 8(b) was presented in the resumed session on 9 July 2021. Under this agenda item, Mr. Christos Ioakeimidis, Marine Litter Expert, presented Working Document UNEP/MED WG.509/11 "Updated Baseline Values and Proposal for Threshold Values for IMAP Common Indicator 22," as well as the relevant proposal for an updated Baseline Value (BV) of 369 items/100m and a Threshold Value (TV) of 130 items/100m for IMAP Common Indicator 22 at regional level.

56. The Meeting reviewed the document UNEP/MED WG.509/11; endorsed the proposed values; and recommended their submission to the upcoming 8th Meeting of EcAp Coordination Group for

approval. The Meeting requested the Secretariat to incorporate the respective values into the upgraded Regional Plan on Marine Litter Management in the Mediterranean, to be submitted for approval to the upcoming COP22 (UNEP/MED IG.25/12, Draft Decision 25/9, Antalya, December 2021).

57. In this regard, the Secretariat brought to the attention of the Contracting Parties the urgent need to submit datasets for IMAP Common Indicator 23 (i.e. seafloor macro-litter and floating micro-plastics) the soonest possible, in line with the IMAP Info System modules, to order to conduct a similar exercise. The Meeting expressed its support to the Secretariat to further advance the relevant work aimed at progressing towards updating the Baseline Value as well as proposing a Threshold Value for IMAP Common Indicator 23.

58. The conclusions and recommendations under this agenda item are presented in Annex III of this report

Agenda item 8(c): Background (Assessment) Concentrations (BC/BAC) for Common Indicator 17 and Upgraded Approach for Environmental Assessment Criteria (EAC) for IMAP Common Indicators 17, 18 and 20

59. Agenda item 8(c) was presented in the resumed session on 9 July 2021. Under this agenda item, the MED POL Monitoring and Assessment Officer presented Working Document UNEP/MED WG.509/12 “Background (Assessment) Concentrations (BC/BAC) for Common Indicator 17 and Upgraded Approach for Environmental Assessment Criteria (EAC) for IMAP Common Indicators 17, 18 and 20.” She introduced the new upgraded regional and sub-regional Mediterranean BC and BAC values for CI17; a proposal of the criteria for IMAP CI20, as well as an approach to upgrade the Mediterranean EACs. She furthermore explained that the data used for developing updated assessment criteria were collected in the IMAP Pilot Info System during its testing phase, and in particular after launching a formal call for reporting of monitoring data in June 2020, along with the monitoring data stored in MED POL database that have not been previously used for calculation of the assessment criteria applied in the 2017 and 2019 assessments. She also provided an explanation of the changes undertaken in line with comments and conclusions of the Meeting of CorMon on Pollution Monitoring.

60. The Meeting reviewed the document UNEP/MED WG.509/12 and recommended its submission to the upcoming 8th Meeting of EcAp Coordination Group for approval.

61. The conclusions and recommendations under this agenda item are presented in Annex III of this report

Agenda item 8(d): Assessment Criteria Methodology for IMAP Common Indicator 13: Pilot Application in Adriatic Sub-region

62. Agenda item 8(d) was presented in the resumed session on 9 July 2021. Under this agenda item, the MED POL Monitoring and Assessment Officer presented Working Document UNEP/MED WG.509/13 “Assessment Criteria Methodology for IMAP Common Indicator 13: Pilot Application in Adriatic Sub-region.” She explained that further to findings of data availability for setting the assessment criteria for nutrients, this working document elaborates possible uses of the various tools and methods for setting the reference conditions and boundary values for Dissolved Inorganic Nitrogen (DIN) and Total Phosphorous (TP) including a methodological approach developed for the Adriatic Sea; and Best Practice Guide for nutrients toolkit (JRC) and FAN/FLU index (Spain) in relevant sub-areas. She also provided an explanation of the changes undertaken in line with comments and conclusions of the Meeting of CorMon on Pollution Monitoring.

63. The Meeting reviewed the document UNEP/MED WG.509/13 and recommended its submission to the upcoming 8th Meeting of EcAp Coordination Group for approval.

64. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 9: MED POL Programme of Work 2022-2023

65. Agenda item 9 was presented in the initial session on 28 May 2021. Under this agenda item, the Secretariat introduced document UNEP/MED WG.509/14 "MED POL Programme of Work 2022-2023 proposal for submission to the MAP Focal Points Meeting." In his presentation, the MED POL Programme Management Officer provided an overview of the key three thematic programmes in which MED POL is involved: "Towards a Pollution and Litter Free Mediterranean Sea and Coast Embracing Circular Economy; Governance; and Together towards a Shared Knowledge and Foresight of the Mediterranean Sea and Coast" focusing on work under the three pollution-related protocols and IMAP. He explained the key deliverables and tasks to be undertaken by MED POL under each programme, along with links and foreseen collaboration during implementation with other MAP components. He also explained how MED POL PoW 2022-2023 will lead to fulfillment of the MTS for MAP for the upcoming period. He also provided insights about foreseen work with external partners in the framework of GEF and EU supported projects in the area of pollution reduction and prevention and marine litter management.

66. The Focal Points pointed out that the PoW was an ambitious proposal. They highlighted the need for allocating sufficient resources for its proper and timely delivery. A number of Contracting Parties expressed the need for prioritization of activities focusing first on those related to the QSR, followed by operationalizing the implementation of the new Regional Plans, and finally securing support for the national monitoring programmes to generate the required monitoring data. The Deputy Coordinator indicated that important resources, financial and human, for a considerable number of the proposed activities will be made available through external projects, particularly the GEF-funded MedProgramme and the EU-funded ML MED II Project and ECAP MED III Project. She also noted that the Secretariat is aiming to strengthen the MED POL team with an additional programme assistant position and requested from the MED POL Focal Points to inform their corresponding MAP Focal Points on the need to further strengthen the MED POL team to effectively deliver its mandate and the related POW activities.

67. Specific comments were also provided by a number of Contracting Parties. Israel requested that the PoW includes an activity for development of a monitoring protocol for microplastics originating from WWTPs. Montenegro requested that the PoW addresses the disposal of obsolete chemicals, particularly Mercury and PCB. Turkey requested clear linkage between the MTS and SDG targets. The Secretariat informed the Meeting that the development of a Protocol on monitoring of microplastics is foreseen in the 2022-2023 biennium and is planned for implementation under the EU-funded ML MED II project. With regard to the request of Montenegro, the Secretariat will assess the possibility of addressing its request through the MedProgramme. Concerning the inter-relation between MTS and SDGs, the Secretariat indicated that this will be addressed in the final version of the MTS document noting that the outputs of the PoW are derived from the MTS.

68. The Meeting congratulated the Secretariat on the Programme of Work and approved the submission of the proposed MED POL activities to the MAP Focal Points Meeting.

Agenda item 12: Harmonization and standardization of IMAP Pollution Cluster Monitoring [2]

a) Monitoring Guidelines/Protocols for IMAP Common Indicators 13, 14, 17, 18, 20 and 23.

[2] Agenda items 10 and 11 for Part I are presented at the end of the Report of the Meeting for its three sessions

b) Monitoring Guidelines/Protocols for Analytical Quality Assurance and Reporting Monitoring Data for IMAP Common Indicators 13, 14, 17, 18 and 20.
c) Monitoring Guidelines/Protocols for Floating Microplastics.

69. The MED POL Programme Monitoring and Assessment Officer, Ms. Jelena Knezevic, presented Working Documents UNEP/MED WG.509/15 to WG.509/33 under agenda items 12(a) and 12(b) providing the Monitoring Guidelines/Protocols for IMAP Common Indicators 13, 14, 17, 18 and 20 as well as their Analytical Quality Assurance and Reporting. The MED POL Associate Project Management Officer for Marine Litter, Mr. Christos Ioakeimidis presented Working Document UNEP/MED WG.509/34 under agenda item 12(c) providing the Monitoring Guidelines/Protocols for IMAP Common Indicator 23 for Floating Microplastics.

70. The Contracting Parties expressed their appreciation of the comprehensive compendium of the Monitoring guidelines for IMAP Common Indicators 13, 14, 17, 18, 20 and 23 aiming to strengthen substantial knowledge for the implementation of the standardized and harmonized IMAP Pollution Cluster monitoring practices and increasing comparability of the national monitoring programmes, while conveying their expectation that these protocols/guidelines will provide much needed support to national IMAP competent laboratories in their endeavors to deliver quality-assured data for the future assessments in the Mediterranean, especially to the ongoing preparation of the 2023 MED QSR.

71. The Contracting Parties further expressed their satisfaction of the work undertaken by the Secretariat-MED POL Programme in collaboration with the International Atomic Energy Agency – Marine Environmental Studies Laboratory (IAEA/MESL) and support of distinguished scientists and experts representing the Contracting Parties.

72. The Contracting Parties took note and agreed with the explanation provided by the Secretariat regarding further work that will be undertaken in collaboration with IAEA/MESL in order to provide optimal design of the Monitoring Guidelines for their practical use by the technical personnel of national IMAP competent laboratories.

73. Finally, the Meeting thanked the Secretariat for its efforts to consistently and thoroughly address the technical proposals provided by national representatives during and immediately after the Integrated Meetings of the Ecosystem Approach Correspondence Groups on IMAP Implementation (CORMONs) in December 2020 and April 2021.

Monitoring Guidelines/Protocols for sampling; sample preservation and transportation of hydrographic physical and chemical parameters

74. The Secretariat presented Working Documents UNEP/MED WG.509/15 to WG.509/20 providing the Monitoring Guidelines/Protocols for sampling; sample preservation and transportation; as well as sample preparation and analysis of hydrographic physical and chemical parameters; key nutrients in seawater (i.e., nitrogen, phosphorous, silica compounds and Chlorophyll *a*) related to IMAP Common Indicators 13 and 14.

75. Further to discussions by the meeting participants, the Contracting Parties agreed to the monitoring methodologies and practices related to IMAP Common Indicators 13 and 14 and approved the Meeting documents UNEP/MED WG.509/15 to 509/20 for their use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

Monitoring Guidelines/Protocols for sampling; sample preservation and transportation of heavy and trace elements and organic contaminants in sediment and biotas

76. The Secretariat presented Working Documents UNEP/MED WG.509/21 to 509/26 providing the Monitoring Guidelines/Protocols for sampling; sample preservation and transportation; as well as sample preparation and analysis of heavy and trace elements and organic contaminants in sediment and biota related to IMAP Common Indicator 17, as well as in seawater as non-mandatory matrix.

77. The Contracting Parties agreed on the monitoring methodologies and practices related to IMAP Common Indicator 17 and approved the Meeting documents UNEP/MED WG.509/21 to 509/26 for their use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

Monitoring Guidelines/Protocols for sampling, sample preparation and biomarkers analysis

78. The Secretariat presented Working Documents UNEP/MED WG.509/27 to 509/29 providing the Monitoring Guidelines/Protocols for sampling, sample preparation and biomarkers analysis, i.e., Lysosomal membrane stability (LMS), Micronuclei (MNi) frequency, Acetylcholinesterase (AChE) activity and Stress on Stress (SoS) of Marine Molluscs (such as Mytilus sp.) and Fish (such as Mullus barbatus) related to IMAP Common Indicator 18.

79. With regard to Working Document UNEP/MED WG.509/27, one meeting participant took the floor to elaborate the written proposals shared with the Secretariat after formal submission of the document on 1st September 2020 proposing the following aspects to be further addressed by: a) amending paragraph 20 with the recommendation that a specific common testing of the period of transportation should be exercised between the Parties; b) introducing a few precisions in paragraph 35 as follows: i) separation of dry soft tissue mass from dry shell mass with "," instead of "/" and adding level of evaluation of the results along with the unit of measure i.e., 0.1 g for dry soft tissue mass and dry shell mass; ii) specifying that dry weight in equation for calculation of Condition Index (CInd) refers to dry soft tissue weight and adding level of evaluation of the result along with the unit of measure i.e., 0.1 g for dry weight and 0.1 cm^3 for internal shell volume; c) introducing a few precisions in paragraph 60 as follows: i) precising that weight refers to total weight for fish biometrics; ii) replacing weight with body eviscerated weight in equation for calculation of the Fulton's condition factor; iii) replacing in equation for measurement of GSI total body weigh with eviscerated weight and precising that eviscerated weight corresponds to the total weight without all internal organs (stomach, liver, gonad, intestine); iv) replacing in equation for measurement of Liver Somatic Index (LSI or HSI) total body weigh with eviscerated weight and deleting "stomach content - liver weight"; v) adding new footnote that refers to Martinez-Gomez et al., 2012.

80. The Secretariat proposed adding an aspect related to precision in paragraph 10 further to its amendment previously undertaken following the request of one participant during the Meeting of CorMon on Pollution Monitoring (26-28 April). A precision "at least of" was added along with a related footnote explaining that a period of 30 days is best for collecting data related to the analysis of biomarkers only; adding that if samples are also taken for chemical analysis, a period of at least 60 days should be ensured, along with providing information on gonad development.

81. Following on the expression of support of another participant to such proposed amendments of paragraphs 10, 20, 35 and 60, the Contracting Parties agreed on the monitoring methodologies and practices elaborated for sampling and sample preservation of Marine Molluscs (such as Mytilus sp.) and Fish (such as Mullus barbatus) for IMAP Common Indicator 18 and approved the meeting document UNEP/MED WG.509/27, as amended in UNEP/MED WG.509/43/L.3/Add.1 during the discussion, for its use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

82. Regarding Working Document UNEP/MED WG.509/28, one meeting participant took the floor to elaborate the written proposals shared with the Secretariat after formal submission of the document on 1st September 2020, proposing to add an aspect on precision in paragraph 42 that the first inspection corresponds to time '0' in Table 1. The Contracting Parties approved the document UNEP/MED WG.509/28 for biomarkers analysis, i.e., Lysosomal membrane stability (LMS), as amended in UNEP/MED WG.509/43/L.3/Add.2 during the discussion, for their use by the IMAP

competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

83. Finally, with regard to Working Document UNEP/MED WG.509/29, one meeting participant elaborated written proposals shared with the Secretariat after formal submission of the document on 1st September 2020, proposing to add: a) an aspect on precision in paragraph 59 whereby the temperature of incubation and reaction must be kept at room or controlled temperature, such as +20°C; and b) including a correction in the denominator of equation for calculation of AChE activity along with an explanation of parameters included in the equation as provided in paragraph 59.

84. Following on the expression of support of another participant to the proposed amendments, the Contracting Parties agreed on the monitoring methodologies and practices elaborated for biomarkers analysis, i.e., Micronuclei (MNi) frequency, Acetylcholinesterase (AChE) activity and Stress on Stress (SoS) of Marine Molluscs (such as Mytilus sp.) and Fish (such as Mullus barbatus) related to IMAP Common Indicator 18 and approved the document UNEP/MED WG.509/29, as amended in UNEP/MED WG.509/43/L.3/Add.3 during the discussion, for their use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

Monitoring Guidelines/Protocols for sampling; sample preservation and transportation of heavy and trace elements and organic contaminants in sea food

85. The Secretariat presented Working Documents UNEP/MED WG.509/30 to 509/31 providing the Monitoring Guidelines/Protocols for sampling, sample preservation and transportation; as well as sample preparation and analysis of heavy and trace elements and organic contaminants in sea food related to IMAP Common Indicator 20.

86. Further to discussions, the Contracting Parties agreed on the monitoring methodologies and practices related to IMAP Common Indicator 20 and approved the Meeting documents UNEP/MED WG.509/30 to 509/31 for their use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

Procedures for Analytical Quality Assurance and Reporting of Monitoring Data

87. The Secretariat presented Working Documents UNEP/MED WG.509/32 to 509/33 providing the procedures for Analytical Quality Assurance and Reporting of Monitoring Data aimed at ensuring the representativeness and accuracy of the analytical results for generation and reporting of quality-assured monitoring data.

88. Further to requesting the Secretariat - INFO/RAC to finalize Data Standards (DSs) and Data Dictionaries (DDs) for IMAP Common Indicators 18 and 20 for their integration in the IMAP Info System in line with the proposals elaborated in Annex IV of the document UNEP/MED WG.509/33, which was shared with the 8th Meeting of EcAp Coordination Group, the Contracting Parties approved the Meeting documents UNEP/MED WG.509/32 and WG.509/33 for their use by the IMAP competent laboratories in order to move forward the implementation of standardized and harmonized IMAP monitoring practices.

Monitoring Guidelines/Protocols for Floating Microplastics

89. The Secretariat presented Working Document UNEP/MED WG.509/34 providing the Monitoring Guidelines/Protocols for Floating Microplastics that extracts from the most commonly applied methodologies for monitoring floating microplastics and presents the basic methodological elements for monitoring floating microplastics in the Mediterranean in line with IMAP requirements. The Secretariat explained that the aim of this protocol is to guide technical personnel of the IMAP competent laboratories on the implementation of standardized and harmonized monitoring practices related to IMAP EO10 (Marine Litter) Common Indicator 23 (Floating Microplastics).

90. The Contracting Parties agreed on the Monitoring Guidelines/Protocols for Floating Microplastics and approved the Working Document UNEP/MED WG.509/34 for their use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results for generation and reporting of quality-assured monitoring data related to IMAP Marine Litter Cluster (Ecological Objective 10, Common Indicator 23), including for the preparation of the 2023 MED QSR.

91. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 13: Common methodologies on estimation techniques for the National Baseline Budget (NBB) of pollutants related to:

a) Non-point source releases from agriculture.
b) Point source releases from aquaculture.
c) Non-point source releases from catchment runoffs.

92. The MED POL Programme Pollution Control Officer, Mr. Erol Cavus, presented Working Documents UNEP/MED WG.509/35 to WG.509/37 providing guidelines on common methodologies on estimation techniques for the National Baseline Budget (NBB) of pollutants related to non-point source releases from agriculture; point source releases from aquaculture; and non-point source releases from catchment runoffs. He briefed meeting participants on the comments received and outcomes of the Expert Meeting which discussed these guidelines in April 2021.

93. Under agenda item 13(a), the Secretariat introduced Working Document UNEP/MED WG.509/35: "Guidelines on estimation techniques and applied methodologies for non-point source releases from agriculture," explaining the scope of the updated NBB Guidelines aiming to support the Contracting Parties to report their pollutants' releases originating from non-point sources from agriculture and providing detailed overview of estimation techniques and approaches of emissions and releases of pollutants from specific non-point agricultural sources.

94. The Focal Points agreed on the Guidelines on estimation techniques and applied methodologies for non-point source releases from agriculture and approved the Working Document UNEP/MED WG.509/35 for their use to report their pollutants' releases originating from non-point source releases from agriculture.

95. Under agenda item 13(b), the Secretariat introduced Working Document UNEP/MED WG.509/37: "Guidelines on estimation techniques and applied methodologies for point source releases from aquaculture," providing information on estimation of releases of Total Nitrogen, Total Phosphorus, Total Organic Carbon (BOD, or COD) and some heavy metals (Cu and Zn and their compounds) originating from the aquaculture sector. The Secretariat emphasized few aspects addressed by the Guidelines including the importance of feed content for the estimation of the releases of TN, TP, TOC as well as the issue of unintentional releases of pesticides, POPs and microliter via fish feeds, noting that there were no agreed estimation techniques for these releases.

96. The Focal Points agreed on the Guidelines on estimation techniques and applied methodologies for point source releases from aquaculture and approved the Working Document

UNEP/MED WG.509/36 for their use to report their pollutants' releases originating from point source releases from aquaculture.

97. Under agenda item 13(c), the Secretariat introduced Working Document UNEP/MED WG.509/38: "Guideline on estimation techniques and applied methodologies for non-point source releases from catchment runoffs". The Secretariat explained the scope of the document by providing specific information on estimation of releases of nutrients, organic carbon and veterinary antibiotics and pharmaceuticals from catchment runoff.

98. The Focal Points agreed on the Guidelines on estimation techniques and applied methodologies for non-point source releases from catchment runoffs and approved the Working Document UNEP/MED WG.509/37 for their use to report their pollutants' releases originating from non-point source releases from catchment runoff.

99. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda item 14: Review of assessments for development of three new Regional Plans in accordance with Article 15 of the LBS Protocol for the biennium 2022-2023 on:

a) Agricultural practices and discharged pollutants reaching the Mediterranean marine environment.
b) Aquaculture practices in the Mediterranean and their impact on the marine environment.
c) State of urban storm water management in the Mediterranean.

100. The MED POL Programme Management Officer, Mr. Mohamad Kayyal, presented Working Documents UNEP/MED WG.509/38 to WG.509/40 providing the outcomes of the assessments carried out in the current biennium to examine and document agricultural practices and discharged pollutants reaching the Mediterranean; aquaculture practices and their impact on the Mediterranean marine environment, in cooperation with Plan Bleu Regional Activity Centre; and state of urban storm water management in the Mediterranean. He stressed the aim of these assessments to provide up-to-date data and information for elaborating the three new Regional Plans on Agriculture Management, Aquaculture Management and Urban Storm Water Management to be developed in the 2022-2023 biennium. As such, he stressed the background nature of these documents stressing that any information based on these assessments which will be incorporated in the clauses of the Regional Plans will be subject to examination and re-evaluation by the expert groups to be designated by the Contracting Parties as part of the preparation process of these Regional Plans.

101. During his presentation of the three assessments under agenda items 14(a), 14(b) and 14(c), the MED POL Programme Management Officer briefed meeting participants on the comments received by the Expert Group Meeting held in April 2021. He illustrated the amendments made in response to the raised comments for each of the three assessments. He also provided answers to comments posed by the meeting participants, in particular, to one participant who inquired about comments provided on the assessment on aquaculture practices (UNEP/MED WG.509/39) which were sent to the Secretariat in the "Draft" Meeting Report of the Experts Meeting held in April 2021 (included as Information Document UNEP/MED WG.509/Inf.19). He confirmed that the Secretariat would address this comment promptly in the "Final" Expert Group Meeting Report to be disseminated to the MED POL Focal Points.

102. Further to discussions, the Meeting introduced specific data and information in document WG.509/39, as appended in Document WG.509/43/L.3 related to Bluefin Tuna farming in the Mediterranean.

103. The Focal Points recommended using the three assessment documents for further elaborating the new Regional Plans on Agriculture, Aquaculture, and Urban Storm Water Management in the Mediterranean as stipulated in the conclusions and recommendations under this agenda item in Annex III of this report.

Agenda item 15: Methodologies and techniques for the assessment and monitoring of adverse impacts of dumping activities.

104. Under agenda item 15, the MED POL Programme Pollution Control Officer introduced the Working Document UNEP/MED WG.509/41 on the "common methodologies and techniques for the assessment and monitoring of adverse impacts of dumping activities." He presented related methodologies and techniques addressing both monitoring of dredging operations from harbors, ports, navigation channels and infrastructure projects, as well as of dredged material disposal sites. He briefed meeting participants on the comments received and outcomes of the Expert Meeting which reviewed this document in April 2021 as stipulated in the draft Information Document UNEP/MED WG.509/Inf.20.

105. Under the same agenda item, the MED POL Programme Pollution Control Officer introduced Working Document UNEP/MED WG.509/42 "Compendium of Best Environmental Practices" aiming to mainstream regional and global good practices under the LC/LP, Baltic Marine Environment Protection Commission (HELCOM), and the Commission on Protecting and Conserving North-East Atlantic and its resources (OSPAR), as well as relevant information found in guidelines published by other international organizations, with a particular focus on management of dredged materials. He elaborated on the document's linkage to findings of the questionnaire, which was sent to the Contracting Parties, based on which this compendium was prepared as stipulated in Information Document UNEP/MED WG.509/Inf.14. He also briefed meeting participants on the comments received and outcomes of the Expert Meeting which examined this document in April 2021 as stipulated in the UNEP/MED WG.509/Inf.20.

106. The conclusions and recommendations under this agenda item are presented in Annex III of this report.

Agenda items 10 and 16: Any other business (Part I and Part II)

107. Under this agenda item (Part I), the Secretariat presented a brief summary the main findings of the document "Cost estimates for the implementation of the key measures of the Regional Plans for wastewater treatment, sewage sludge and marine litter management with evaluation of related socio-economic benefits" (UNEP/MED WG.509/Inf.7). The MED POL Focal Points were invited to provide their feedback on the approaches used in the study; findings and recommendations as outlined in the document. The Meeting participants agreed to submit the cost assessment study as an information document to the MAP Focal Points Meeting and COP22.

108. During the resumed session of Part I, the Focal Points bid farewell to the MED POL Focal Point from Slovenia, Ms. Valentina Turk. The Coordinator expressed her appreciation for the involvement of Ms. Turk with UNEP/MAP and especially her contributions in the field of monitoring and assessment. The Meeting wished Ms. Turk success in her future professional endeavors.

109. No issues were raised for this agenda item during Part II of the Meeting.

Agenda items 11 and 17: Conclusions and recommendations (Part I and Part II)

110. The Meeting reviewed, commented on, and approved the draft Conclusions and Recommendations reports for both parts of the Meeting as amended and attached to the present report in Annex III including their corresponding appendices, revised as appropriate, by the Meeting.

Agenda item 18: Closure of Meeting

111. Further to expressing the usual courtesies, the Chair concluded the meeting expressing special thanks and sincere appreciation to all participants for their commitment during the three sessions of the Meeting in 27-28 May, 9 July and 6-7 October 2021.

112. The Chair closed the MED POL Focal Points Meeting at 16:00 on Thursday 7 October 2021.

Annex I

List of Participants

REPRESENTATIVES OF THE CONTRACTING PARTIES / REPRESENTANTS DES PARTIES CONTRACTANTES

Albania

Ms. Klodiana Marika,
Director, Ministry of Tourism and Environment

Ms. Ledjana Bojaxhi,
Head of sector
Ministry of Tourism and Environment

Mr. Elson Thana,
Expert in the Department of Maritime Transport Policies at Ministry of Infrastructure and Energy

Algeria

Mme. Souad Boustila,
Ingenieur en environnement chez Ministere de l'environnement

Bosnia and Herzegovina

Ms. Selma Cengic,
Executive Director · Hydro Engineering Institute Sarajevo (HEIS)

Ms. Senida Dzajic –
Researcher, Hydro Engineering Institute Sarajevo (HEIS)

Croatia

Ms. Barbara Skevin Ivosevic,
Senior Advisor. Ministry of Environmental and Nature Protection

Ms. Jasmina Antolic,
Ministry of Environmental and Nature Protection

Ms. Nela Palarić,
Head of Service for Licences and transboundary movement of Waste, Ministry of Economy and Sustainable development

Mr. Pero Tutman,
Scientific advisor, Institute of Oceanography and Fisheries

Ms. Marija Šikoronja,
Hrvatske vode (Croatian water)

Cyprus

Mr. Konstantinos Antoniadis,
Department of Fisheries and Marine Research

Ms. Antonia Achilleos,
Department of Environment, Limassol

Egypt

Mr. Sameh Ayoub,
MEDPOL Focal Point, Egyptian Environmental Affairs Agency

Soha Shabaka,
National Institute of Oceanography and Fisheries

European Union

Mr. Georg Hanke,
European Commission Joint Research Centre. Directorate D,
Sustainable Resources Water and Marine Resources Unit

France

Mme. Emmanuelle Thiesse,
Chargée de mission pollutions et fonds marins, Ministère de la transition écologique

Mr. Francois Galgani,
IFREMER / EU mission board member (Healthy Ocean)

Greece

Ms. Maria Gini,
Head of the Division of Protection and Water Resources Management, Ministry of Environment and Energy

Israel

Mr. Rani Amir,
Director MCED, Ministry of Environmental Protection

Mr. Frederic Arzoine,
Ministry of Environmental Protection

Ms. Maisa Inibtawi,
Marine Pollution Prevention Coordinator - Land-Based Sources,
Ministry of Environmental Protection

Italy

Ms. Cecilia Silvestri,

The Italian Institute for Environmental Protection and Research (ISPRA)

Mr. Cristian Mugnai,
The Italian Institute for Environmental Protection and Research (ISPRA)

Ms. Daniela Berto,
The Italian Institute for Environmental Protection and Research (ISPRA)

Ms. Erika Magaletti,
The Italian Institute for Environmental Protection and Research (ISPRA)

Mr. Francesco Mundo,
The Italian Institute for Environmental Protection and Research (ISPRA)

Ms. Ginevra Moltedo,
The Italian Institute for Environmental Protection and Research (ISPRA)

Mr. Marco Matiddi,
The Italian Institute for Environmental Protection and Research (ISPRA)

Ms. Nicoletta Calace,
The Italian Institute for Environmental Protection and Research (ISPRA)

Ms. Silvana Salvati,
The Italian Institute for Environmental Protection and Research (ISPRA)

Lebanon

Ms. Marwa El Mokdad,
Environmental Engineer, Ministry of Environment

Mr. Najib Abi Chedid,
Environmental Expert, Ministry of Environment

Libya

Mr. Meftah El Madni,
Ministry of Environment, Tripoli

Malta

Ms. Tamara Micallef,
Environment and Resources Authority

Monaco

Mr. Philippe Antognelli,
Head of Section, Direction de l'Environnement

Montenegro

Ms. Ana Misurovic,
Environment Protection Agency

Ms. Ivana Mitrovic,
Advisor, Environment Protection Agency

Ms. Ivana Stojanovic,
Head of Division for Integrated management of Marine and Land Ecosystems, Ministry of Ecology, Spatial Planning and Urbanism,

Mr. Novica Mijovic,
Port State Control Officer, Ministry of Capital Investment

Mr. Obrad Djokovic,
Port State Control Officer, Ministry of Capital Investments

Mr. Sergej Vujosevic,
Ministry of capital investment, Bar

Ms. Snežana Didanović,
Ministry of Ecology, Spatial Planning and Urbanism, Podgorica

Morocco

Mr. Abdelkader Ajir,

Annex II

Agenda of the Meeting

Agenda item 1: Opening of the Meeting.

Agenda item 2: Election of Officers.

Agenda item 3: Organizational Matters and Adoption of the Agenda.

Agenda item 4: Progress achieved regarding implementation of the Programme of Work 2020-2021 related to Land-Based Pollution and Governance Themes.

Agenda item 5: Updates of the annexes of the pollution-related protocols:

a) Land-Based Sources (LBS) Protocol.
b) Protocol for the Prevention and Elimination of Pollution of the Mediterranean Sea by Dumping from Ships and Aircraft or Incineration at Sea.

Agenda item 6: Review of the new/upgraded Regional Plans in accordance with Article 15 of the LBS Protocol on:

a) Urban Wastewater Treatment.
b) Sewage Sludge Management.
c) Marine Litter Management in the Mediterranean.

Agenda item 7: Indicator-based midterm evaluation of the implementation of National Action Plans/Programme of Measures (2015-2020).

Agenda item 8: Cross-Cutting Issues - The Integration and Aggregation Rules for IMAP Ecological Objectives 5, 9 and 10 and Assessment Criteria for Contaminants, Nutrients and Marine Litter:

a) Integration and Aggregation Rules for Monitoring and Assessment of (IMAP Pollution and Marine Litter Cluster.
b) Updated Baseline Values and Proposal for Threshold Values for IMAP Common Indicator 22.
c) Background (Assessment) Concentrations (BC/BAC) for Common Indicator 17 and Upgraded Approach for Environmental Assessment Criteria (EAC) for IMAP Common Indicators 17, 18 and 20.
d) Assessment Criteria Methodology for IMAP Common Indicator 13: Pilot Application in Adriatic Sub-region.

Agenda item 9: MED POL Programme of Work 2022-2023.

Agenda item 10: Any other business *(in relation to agenda items 1 to 9).*

Agenda item 11: Conclusions and recommendations *(in relation to agenda items 1 to 9).*

Agenda item 12: Harmonization and standardization of IMAP Pollution Cluster Monitoring:

d) Monitoring Guidelines/Protocols for IMAP Common Indicators 13, 14, 17, 18, 20 and 23.
e) Monitoring Guidelines/Protocols for Analytical Quality Assurance and Reporting Monitoring Data for IMAP Common Indicators 13, 14, 17, 18 and 20.
f) Monitoring Guidelines/Protocols for Floating Microplastics.

Agenda item 13: Common methodologies on estimation techniques for the National Baseline Budget (NBB) of pollutants related to:

a) Non-point source releases from agriculture.
b) Point source releases from aquaculture.
c) Non-point source releases from catchment runoffs.

Agenda item 14: Review of assessments for development of three new Regional Plans in accordance with Article 15 of the LBS Protocol for the biennium 2022-2023 on:

a) Agricultural practices and discharged pollutants reaching the Mediterranean marine environment.
b) Aquaculture practices in the Mediterranean and their impact on the marine environment.
c) State of urban storm water management in the Mediterranean.

Agenda item 15: Methodologies and techniques for the assessment and monitoring of adverse impacts of dumping activities.

Agenda item 16: Any other business *(in relation to agenda items 12 to 15)*

Agenda item 17: Conclusions and recommendations *(in relation to agenda items 12 to 15)*

Agenda item 18: Closure of the Meeting

Annex III

Conclusions and Recommendations

Conclusions and Recommendations of the Initial Session of Part I of the Meeting of the MED POL Focal Points, 27-28 May 2021

On 27 and 28 May 2021, the First Session of the Meeting of the MED POL Focal Points was held by videoconference. The meeting was organized by UNEP/MAP Secretariat (MED POL Programme). Further to its deliberations, the Meeting reached the following conclusions:

1. The Meeting reviewed the draft amendments to the Annexes to the LBS Protocol and recommended the final draft revised version as contained in Appendix I to these conclusions for submission to the Meeting of the MAP Focal Points for their consideration.

2. The Meeting reviewed the draft amendments of the Annex to the Dumping Protocol and recommended the final draft revised version as contained in Appendix II to these conclusions for submission to the Meeting of the MAP Focal Points for their consideration.

3. The Meeting reviewed the Draft Regional Plan on Urban Wastewater Treatment in the Framework of Article 15 of the LBS Protocol and recommended the final draft revised version as contained in Appendix III to these conclusions for submission to the Meeting of the MAP Focal Points for their consideration.

4. The Meeting reviewed the Draft Regional Plan on Sewage Sludge Management in the Framework of Article 15 of the LBS Protocol and recommended the final draft revised version as contained in Appendix IV to these conclusions for submission to the Meeting of the MAP Focal Points for their consideration.

5. The Meeting reviewed the Draft Updated Regional Plan on Marine Litter Management in the Mediterranean in the Framework of Article 15 of the LBS Protocol and recommended the final draft revised version as contained in Appendix V to these conclusions for submission to the Meeting of the MAP Focal Points for their consideration.

6. The Meeting reviewed the proposed Programme of Work for the new biennium 2022-2023 and recommended the final draft revised version as contained in Appendix VI to these conclusions for integration into the MAP Programme of Work. The Meeting highlighted the need to prioritize the activities, particularly contribution to the delivery of the QSR pollution and litter cluster; and operationalizing of the implementation of the Regional Plans measures as well as their effectiveness, as well as implementation of the national IMAPs.

7. The Meeting requested the Secretariat to rationalize the number of meetings to enhance the effectiveness of the work and requested the Secretariat to consider additional resources to support MED POL work.

8. The Meeting requested the Secretariat to organize a “resumed session” of Part I of the MED POL Focal Points Meeting to review agenda items that could not be addressed due to time constraints at the present session. The Secretariat confirmed that the resumed session will be held on 9 July 2021.

Conclusions and Recommendations of the Resumed Session of Part I of the Meeting of the MED POL Focal Points, 9 July 2021

On 9 July 2021, the "resumed session" of the First Part of the Meeting of the MED POL Focal Points was held by videoconference. The meeting was organized by UNEP/MAP Secretariat (MED POL Programme) and focused on agenda items not covered during the First Session of the Meeting that convened on 27 and 28 May 2021. Further to its deliberations, the Meeting reached the following conclusions:

9. Further to its review of Working Document UNEP/MED WG.509/9 "Indicator-based midterm evaluation of the implementation of National Action Plans/Programme of Measures (2015-2020)," the Meeting took note of progress achieved by the Contracting Parties to the Barcelona Convention in the implementation of the National Action Plans for the years 2015-2020, as well as the gaps identified in the evaluation report. The Meeting requested the Secretariat (MEDPOL) to continue supporting the Contracting Parties for implementation of the National Action Plans and to consider bridging the gaps highlighted in the conclusions of the evaluation. The Meeting confirmed the fulfillment of the mandate given to the Secretariat to undertake the evaluation as stipulated in Decision IG.22/8 (COP 19, Athens, Greece, 9-12 February 2016), and recommended submission of Document UNEP/MED WG.509/9 to the MAP Focal Points Meeting in September 2021.

10. The Meeting reviewed Working Document UNEP/MED WG.509/10/rev.2 "Integration and Aggregation Rules for Monitoring and Assessment of IMAP Pollution and Marine Litter Cluster." The Meeting appreciated the work quality and in-depth analysis undertaken by the Secretariat to develop the proposed integration and aggregation methodology. The Meeting did not reach consensus on the document, and although some Contracting Parties (Croatia, Bosnia and Herzegovina, Montenegro, Greece) were in favor of submitting the document to the EcAP Coordination Group, the Meeting recommended that the document be returned to the CorMon for further clarifications from technical and scientific considerations with a view to avoid possible confusion with the scope/mandate of the Barcelona Convention and its Protocols. The Meeting also requested the Secretariat to include in the report of the meeting information on the reasons why the First Session of the MED POL Focal Points Meeting decided to remove document WG.509/inf14 from the list of documents.

11. The Meeting reviewed Working Document UNEP/MED WG.509/11 "Updated Baseline Values and Proposal for Threshold Values for IMAP Common Indicator 22." The Meeting thanked the Secretariat for updating the Baseline Values (BV) and proposing Threshold Values (TV) further to a commonly agreed methodology. The Meeting recommended submission of Document UNEP/MED WG.509/11 to the 8th EcAp Coordination Group Meeting in September 2021 for its consideration. The Meeting equally recommended the submission of the updated Baseline Values (BV) and proposed Threshold Values (TV) for adoption by COP22.

12. The Meeting reviewed Working Document UNEP/MED WG.509/12 "Background (Assessment) Concentrations (BC/BAC) for Common Indicator 17 and Upgraded Approach for Environmental Assessment Criteria (EAC) for IMAP Common Indicators 17, 18 and 20." The Meeting appreciated the work undertaken by the Secretariat and recommended submission of Document UNEP/MED WG.509/12 to the 8th EcAp Coordination Group Meeting in September 2021 for its consideration.

13. The Meeting reviewed Working Document UNEP/MED WG.509/13 "Assessment Criteria Methodology for IMAP Common Indicator 13: Pilot Application in Adriatic Subregion." The Meeting took note and thanked the Secretariat of the work undertaken and recommended submission of Document UNEP/MED WG.509/13 to the 8th EcAp Coordination Group Meeting in September 2021 for its consideration.

14. Further to presentation of Working Document UNEP/MED WG.509/3 "Progress achieved regarding implementation of the Programme of Work 2020-2021 related to Land-Based Pollution and Governance Themes," the Meeting acknowledged the progress achieved and appreciated the work undertaken by MED POL and the Contracting Parties to achieve the planned outputs as mandated in the PoW for the biennium 2020-2021.

Conclusions and Recommendations of Part II of the Meeting of the MED POL Focal Points, 6-7 October 2021

On 6 and 7 October 2021, the Meeting of the MED POL Focal Points – Part II was held by videoconference. The meeting was organized by UNEP/MAP Secretariat (MED POL Programme).

15. Further to its deliberations, the Meeting reached the following conclusions:

15.1 Monitoring Guidelines/Protocols for IMAP Common Indicators 13, 14, 17, 18, 20 and 23

a) The Meeting acknowledged the excellent work undertaken by the Secretariat – MED POL in collaboration with the International Atomic Energy Agency – Marine Environmental Studies Laboratory (IAEA/MESL) and with the support of the distinguished scientists and experts representing the Contracting Parties towards strengthening the substantial knowledge for the implementation of the standardized and harmonized IMAP Pollution Cluster monitoring practices and increasing the comparability of the national monitoring programmes. The Meeting expressed an appreciation for their efforts made to consistently and thoroughly address the technical proposals provided during and immediately after the Integrated Meetings of the Ecosystem Approach Correspondence Groups on IMAP Implementation (CORMONs) (Videoconference, 1-3 Dec. 2020) and the Meeting of CorMon on Pollution Monitoring (Videoconference, 26-28 April 2021).

b) The Meeting agreed on the monitoring methodologies and practices recommended for sampling; sample preservation and transportation; as well as sample preparation and analysis of hydrographic physical and chemical parameters, key nutrients in seawater (i.e., nitrogen, phosphorous, silica compounds) and Chlorophyll *a* related to IMAP Common Indicators 13 and 14, and approved the Meeting documents UNEP/MED WG.509/15 to 509/20 for their use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

c) The Meeting agreed on the monitoring methodologies and practices elaborated for sampling; sample preservation and transportation; as well as sample preparation and analysis of heavy and trace elements and organic contaminants in sediment and biota related to IMAP Common Indicator 17, as well as in seawater as non-mandatory matrix, and approved the Meeting documents UNEP/MED WG.509/21 to 509/26 for their use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

d) The Meeting agreed on the monitoring methodologies and practices elaborated for sampling, sample preparation and biomarkers analysis, i.e. Lysosomal membrane stability (LMS), Micronuclei (MNi) frequency, Acetylcholinesterase (AChE) activity and Stress on Stress (SoS) of Marine Molluscs (such as Mytilus sp.) and Fish (such as Mullus barbatus) related to IMAP Common Indicator 18 and approved the Meeting documents UNEP/MED WG.509/27, WG.509/28 and WG.509/29, as amended during the discussion, as presented in WG.509/43/L.3, for their use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

e) The Meeting agreed on the monitoring methodologies and practices elaborated for sampling, sample preservation and transportation; as well as sample preparation and analysis of heavy and trace elements and organic contaminants in sea food related to IMAP Common Indicator 20 and approved the Meeting documents UNEP/MED WG.509/30 and WG.509/31 for their use by the IMAP competent laboratories in order to ensure the representativeness and

accuracy of the analytical results related to IMAP Pollution Cluster, including for the preparation of the 2023 MED QSR.

f) The Meeting agreed on the procedures for Analytical Quality Assurance and Reporting of Monitoring Data elaborated in respective protocols in order to ensure the representativeness and accuracy of the analytical results for generation and reporting of quality-assured monitoring data and approved the Meeting documents UNEP/MED WG.509/32 and WG.509/33 for their use by the IMAP competent laboratories in order to move forward the implementation of standardized and harmonized IMAP monitoring practices.

g) The Meeting requested the Secretariat - INFO/RAC to finalize Data Standards (DSs) and Data Dictionaries (DDs) for IMAP Common Indicators 18 and 20 for their integration in the IMAP Info System by taking into account the proposals elaborated in Annex IV of the Meeting document UNEP/MED WG.509/33 and shared with the 8th Meeting of the EcAp Coordination Group further to the technical requests provided during the Meeting of CorMon on Pollution Monitoring (26-28 April 2021), in order to support reporting of monitoring data for IMAP CIs 18 and 20 for preparation of the 2023 MED QSR.

h) The Meeting agreed on the Monitoring Guidelines/Protocols for Floating Microplastics and approved the Meeting Document UNEP/MED WG.509/34, as presented in WG.509/43/L.3, for its use by the IMAP competent laboratories in order to ensure the representativeness and accuracy of the analytical results related to IMAP Marine Litter Cluster (Ecological Objective 10, Common Indicator 23), including for the preparation of the 2023 MED QSR.

i) The Meeting acknowledged that the scope and purpose of the document (i.e. to focus explicitly on microplastics) is in line with the IMAP Common Indicator 23. The Meeting took note that micro-litter is not comprising only of microplastics and that additional material can be found floating in the water column. The Meeting recommended to the Secretariat to consult on this matter with experts representing the Contracting Parties at the next CORMON Marine Litter Meeting in 2022 in order to explore, as need be, the ways of incorporating additional micro-litter categories in document UNEP/MED WG.509/34.

j) The Meeting took note of further work of the Secretariat that will be undertaken in collaboration with IAEA/MESL in order to provide optimal design of the Monitoring Guidelines for their practical use by the technical personnel of national IMAP competent laboratories.

k) The Meeting expressed an expectation that the Monitoring guidelines prepared for IMAP Common Indicators 13, 14, 17, 18, 20 and 22 will provide great support to national IMAP competent laboratories in their endeavors to deliver quality-assured data for the future assessments in the Mediterranean, especially to the ongoing preparation of the 2023-MED QSR.

15.2 Common methodologies on estimation techniques for the National Baseline Budget (NBB) of pollutants

a) The Meeting appreciated the work undertaken by the Secretariat for preparation of the Guidelines on estimation techniques and applied methodologies for non-point source releases from agriculture and from catchment runoffs corresponding to Meeting documents UNEP/MED WG.509/35 and WG.509/37, respectively. The Meeting approved the documents and recommended the use of the aforementioned Guidelines for the preparation of the 5th Cycle of NBB update for the biennium 2024-2025, including for the preparation of the Final Indicator-Based Evaluation of NAP Implementation.

b) The Meeting appreciated the work undertaken by the Secretariat for preparation of the Guideline on estimation techniques and applied methodologies for point source releases

from aquaculture as iterated in Meeting document UNEP/MED WG.509/36. The Meeting approved the document and recommended the use of the aforementioned Guideline for the preparation of the 5th Cycle of NBB update for the biennium 2024-2025. The Meeting further recommended its use to plan the collection of data for assessment of pressures and development of an indicator on nutrient releases from the aquaculture sector.

15.3 Review of assessments for development of three new Regional Plans in the biennium 2022-2023 on agricultural, aquaculture, and urban storm water management

a) The Meeting appreciated the work undertaken by the Secretariat for preparation of the assessments on (i) agricultural practices and discharged pollutants reaching the Mediterranean marine environment; (ii) aquaculture practices in the Mediterranean and their impact on the marine environment, in cooperation with Plan Bleu Regional Activity Centre; and (iii) state of urban storm water management in the Mediterranean, as iterated in meeting documents UNEP/MED WG.509/38, WG.509/39 and WG.509/40. The Meeting took note of the assessments' findings and introduced specific data and information in document WG.509/39, as presented in WG.509/43/L.3, related to Bluefin Tuna farming in the Mediterranean. The Meeting recommended using the three assessment documents for further elaborating the new Regional Plans on Agriculture, Aquaculture, and Urban Storm Water Management.

15.4 Methodologies and techniques for the assessment and monitoring of adverse impacts of dumping activities

a) The Meeting agreed on the methodologies and techniques for the assessment and monitoring of adverse impacts of dumping activities included in Meeting Document UNEP/MED WG.509/41. The Meeting appreciated the close collaboration with IMO LC/LP (London Convention/London Protocol) to develop the aforementioned methodologies and techniques and approved their use for the assessment and monitoring of adverse impacts of dumping activities, as well as to facilitate the reporting obligations of the Contracting Parties with the aim of achieving more compatible and comparable data under the Dumping Protocol.

b) The Meeting reviewed the Compendium of Best Practices for implementation of the Dumping Protocol as iterated in Meeting Document UNEP/MED WG.509/42. The Meeting appreciated the work undertaken by the Secretariat showcasing examples for monitoring of dredging and disposal operations and approved the submission of the document for publication.

Appendix 1

Proposals for Updating the Annexes to the LBS Protocol

LAND-BASED SOURCES (LBS) PROTOCOL
ANNEX I: ELEMENTS TO BE TAKEN INTO ACCOUNT IN THE PREPARATION OF ACTION PLANS, PROGRAMMES AND MEASURES FOR THE ELIMINATION OF POLLUTION FROM LAND-BASED SOURCES AND ACTIVITIES [3]

This annex contains elements which will be taken into account in the preparation of action plans, programmes and measures for the elimination of pollution from land-based sources and activities referred to in articles 5, 7 and 15 of this Protocol.

Such action plans, programmes and measures will aim to cover the sectors of activity listed in section A and also cover the groups of substances enumerated in section C, selected on the basis of the characteristics listed in section B of the present annex.

Priorities for action should be established by the Parties, on the basis of the relative importance of their impact on public health, the environment and socio-economic and cultural conditions. Such programmes should cover point sources, diffuse sources and atmospheric deposition.
In preparing action plans, programmes and measures, the Parties, in conformity with the Global Programme of Action for the Protection of the Marine Environment from Land-based Activities, adopted in Washington, D.C. in 1995, will give priority to substances that are toxic, persistent and liable to bioaccumulate, in particular to persistent organic pollutants (POPs), as well as to wastewater treatment and management.

A. SECTORS OF ACTIVITY
The following sectors of activity (not listed in order of priority) will be primarily considered when setting priorities for the preparation of action plans, programmes and measures for the elimination of the pollution from land-based sources and activities:
1. Energy production;
2. Fertilizer production;
3. Production and formulation of biocides;
4. The pharmaceutical industry;
5. Petroleum refining;
6. The paper, paper-pulp and wood production and processing industry;
7. Cement production;
8. The tanning and dressing industry including leather dyeing and finishing;
9. The metal industry including thermal processes in the metallurgical industry;
10. Mining and quarrying;
11. The shipbuilding and repairing industry;
12. Harbour operations;
13. The textile industry including textile pre-treatment, dyeing and finishing;
14. The electronic industry;
15. The recycling industry;
16. Other sectors of the organic chemical industry;
17. Other sectors of the inorganic chemical industry;
18. Tourism and leisure activities and infrastructure, including cruise shipping;
19. Agriculture;
20. Animal husbandry including animal slaughterhouses and animal by-products industries;
21. Food processing;
22. Aquaculture and fishing;
23. Treatment and disposal of hazardous wastes;
24. Treatment and disposal of urban wastewater;

[3] Gray highlighted text reflects changes introduced to update the annex

25. Management, including treatment and disposal, of urban solid waste;
26. Disposal of sewage sludge;
27. The waste management industry;
28. Incineration of waste and management of its residues;
29. Works which cause physical alteration of the natural state of the coastline including physical restructuring of rivers, coastline or seabed (water management);
30. Transport;
31. Construction;
32. Water collection and supply including desalination of seawater.
33. Mixed industrial zones including at least one of the above sectors.

B. CHARACTERISTICS OF SUBSTANCES IN THE ENVIRONMENT

For the preparation of action plans, programmes and measures, the Parties should take into account the characteristics listed below:

1. Persistence;
2. Toxicity or other noxious properties (e.g. carcinogenicity, mutagenicity, teratogenicity);
3. Bioaccumulation;
4. Radioactivity;
5. The ratio between observed concentrations and no observed effect concentrations (NOEC);
6. The risk of eutrophication of anthropogenic origin;
7. Health effects and risks;
8. Transboundary significance;
9. The risk of undesirable changes in the marine ecosystem and irreversibility or durability of effects, in particular:

a) adverse impacts on species composition and spatial and temporal variation per species/population, including distribution, abundance, and/or biomass, fecundity, survival and mortality/injury rates and behavior
b) adverse impacts on habitats characteristics;

10. Interference with the sustainable exploitation of living resources or with other legitimate uses of the sea;
11. Effects on the taste and/or smell of marine products for human consumption;
12. Effects on the smell, colour, transparency or other characteristics of seawater;
13. Distribution pattern (i.e. quantities involved, use patterns and probability of reaching the marine environment);
14. Potential for long-range environmental transport.

C. CATEGORIES OF SUBSTANCES

The following categories of substances and sources of pollution will serve as guidance in the preparation of action plans, programmes and measures:

1. Organohalogen compounds and substances which may form such compounds in the marine environment. Priority will be given to Aldrin, Chlordane, DDT, Dieldrin, Dioxins and Furans, Endrin, Heptachlor, Hexachlorobenzene, Mirex, PCBs, Toxaphene; Polychlorinated Biphenyls (PCBs), Polychlorinated dibenzodioxins (PCDDs), Polychlorinated dibenzofurans (PCDFs), endosulfan and its related isomers, hexachlorocyclohexane, Diethylhexylphthalate (DEHP), Chlordecone, Hexabromobiphenyl, Hexabromodiphenyl ether and heptabromodiphenyl ether, Lindane, Pentachlorobenzene, Tetrabromodiphenyl ether and pentabromodiphenyl ether, Perfluorooctane sulfonic acid and its salts, and perfluorooctane sulfonyl fluoride, hexabromocyclododecane (HBCD), hexachlorobutadiene, pentachlorophenol and its salts and esters, and polychlorinated naphthalenes;
2. Total suspended particulates, total Volatile Organic Compounds (VOC), Nitrogen oxides, NH3, sulfur oxide;
3. Organophosphorus compounds and silicon substances which may form such compounds in the marine environment;
4. Organotin compounds and substances which may form such compounds in the marine environment;

5. Polycyclic aromatic hydrocarbons;
6. Heavy metals and their compounds. Priority given to chromium, cadmium, lead, mercury, nickel, organic tin compounds, organic mercury compounds and organic lead compounds;
7. Used lubricating oils;
8. Radioactive substances, including their wastes, when their discharges do not comply with the principles of radiation protection as defined by the competent international organizations, taking into account the protection of the marine environment;
9. Biocides and their derivatives;
10. Pathogenic microorganisms;
11. Crude oils and hydrocarbons of petroleum origin;
12. Cyanides and fluorides;
13. Non-biodegradable detergents and other nonbiodegradable surface-active substances;
14. Compounds of nitrogen and phosphorus and other substances which may cause eutrophication, including biodegradable substances expressed as Biological Oxygen Demand (BOD) or Chemical Oxygen Demand (COD) or Total Organic Carbon (TOC), Total Nitrogen and Total Phosphorus;
15. Litter (any persistent manufactured or processed solid material which is discarded, disposed of, or abandoned in the marine and coastal environment) including plastics, microplastic and micro-sized litter;
16. Thermal discharges and input of other forms of energy;
17. Acid or alkaline compounds which may impair the quality of water;
18. Non-toxic substances that have an adverse effect on the oxygen content of the marine environment;
19. Non-toxic substances that may interfere with any legitimate use of the sea;
20. Non-toxic substances that may have adverse effects on the physical or chemical characteristics of seawater.
21. Brine;
22. Phenolic compounds, brominated flame retardants, polycyclic aromatic hydrocarbons and short chain chlorinated parafins;
23. Chemicals used for the preservation and/or treatment of wood, timber, wood pulp, cellulose, paper, hides and textiles.

ANNEX II: ELEMENTS TO BE TAKEN INTO ACCOUNT IN THE ISSUE OF THE AUTHORIZATIONS FOR DISCHARGES OF WASTES

With a view to the issue of an authorization for the discharges of wastes containing substances referred to in article 6 to this Protocol, particular account will be taken, as the case may be, of the following factors:

A. CHARACTERISTICS AND COMPOSITION OF THE DISCHARGES

1. Type and size of point or diffuse source (e.g. industrial process).
2. Type of discharges (e.g. origin, average composition).
3. State of waste (e.g. solid, liquid, sludge, slurry).
4. Total amount (volume discharged, e.g. per year).
5. Discharge pattern (continuous, intermittent, seasonally variable, etc.).
6. Concentrations with respect to relevant constituents of substances listed in annex I and of other substances as appropriate.
7. Physical, chemical and biochemical properties of the waste discharges.

B. CHARACTERISTICS OF DISCHARGE CONSTITUENTS WITH RESPECT TO THEIR HARMFULNESS

1. Persistence (physical, chemical, biological) in the marine environment.
2. Toxicity and other harmful effects.
3. Accumulation in biological materials or sediments.
4. Biochemical transformation producing harmful compounds.

5. Adverse effects on the oxygen content and balance.
6. Susceptibility to physical, chemical and biochemical changes and interaction in the aquatic environment with other sea-water constituents which may produce harmful biological or other effects on any of the uses listed in section E below.
7. All other characteristics as listed in annex I, section B.

C. CHARACTERISTICS OF DISCHARGE SITE AND RECEIVING ENVIRONMENT
1. Hydrographic, meteorological, geological and topographical characteristics of the coastal area.
2. Location and type of the discharge (outfall, canal outlet, etc.) and its relation to other areas (such as amenity areas, spawning, nursery, and fishing areas, shellfish grounds) and other discharges.
3. Initial dilution achieved at the point of discharge into the receiving environment.
4. Dispersion characteristics such as effects of currents, tides and wind on horizontal transport and vertical mixing.
5. Receiving water characteristics with respect to physical, chemical, biological and ecological conditions in the discharge area, as well as the ecosystem functions and processes, in particular temperature, hydrology, bathymetry, turbidity, transparency, sound, salinity, nutrients, organic carbon, chlorophyll, dissolved gases, acidity (pH), links between species of marine birds, mammals, reptiles, fish and cephalopods and habitats, pelagic-benthic community shifts and productivity.
6. Capacity of the receiving marine environment to receive waste discharges without undesirable effects.

D. AVAILABILITY OF WASTE TECHNOLOGIES
The methods of waste reduction and discharge for industrial effluents as well as domestic sewage should be selected taking into account the availability and feasibility of:
(a) Alternative treatment processes;
(b) Re-use or elimination methods;
(c) On-land disposal alternatives;
(d) Appropriate low-waste technologies.

E. POTENTIAL IMPAIRMENT OF MARINE ECOSYSTEMS AND SEA-WATER USES
1. Effects on human health through pollution impact on:
(a) Edible marine organisms extraction and cultivation of living resources;
(b) Bathing waters;
(c) Aesthetics including color and odor;
2. Effects on marine ecosystems including food webs, in particular living resources, endangered species and critical habitats including from:
(a) Noise
(b) Artificial light
(c) Acidification
(d) Hydrographic changes
3. Physical restructuring of rivers, coastline or seabed
4. Effects on other legitimate uses of the sea.

ANNEX III: CONDITIONS OF APPLICATION TO POLLUTION TRANSPORTED THROUGH THE ATMOSPHERE

This annex defines the conditions of application of this Protocol to pollution from land-based sources transported by the atmosphere in terms of Article 4.1(b) are the following:
1. This Protocol shall apply to polluting discharges into the atmosphere under the following conditions:
(a) the discharged substance is or could be transported to the Mediterranean Sea Area under prevailing meteorological conditions;

(b) the input of the substance into the Mediterranean Sea Area is hazardous for the environment in relation to the quantities of the same substance reaching the Area by other means.
2. This Protocol shall also apply to polluting discharges into the atmosphere affecting the Mediterranean Sea Area from land-based sources within the territories of the Parties and from fixed manmade offshore structures, subject to the provisions of article 4.2 of this Protocol.
3. In the case of pollution of the Mediterranean Sea Area from land-based sources through the atmosphere, the provisions of articles 5 and 6 of this Protocol shall apply progressively to appropriate substances and sources listed in annex I to this Protocol as will be agreed by the Parties.
4. Subject to the conditions specified in paragraph 1 of this annex, the provisions of Article 7.1 of this Protocol shall also apply to:
(a) discharges - quantity and rate - of substances emitted to the atmosphere, on the basis of the information available to the Contracting Parties concerning the location and distribution of air pollution sources;
(b) the content of hazardous substances in fuel and raw materials;
(c) the efficiency of air pollution control technologies and more efficient manufacturing and fuel burning processes;
(d) the application of hazardous substances in agriculture and forestry.
5. The provisions of annex II to this Protocol shall apply to pollution through the atmosphere whenever appropriate. Air pollution monitoring and modelling using acceptable common emission factors and methodologies shall be carried out in the assessment of atmospheric deposition of substances, as well as in the compilation of inventories of quantities and rates of pollutant emissions into the atmosphere from land-based sources.
6. All Articles, including parts thereof to this Protocol not mentioned in paragraphs 1 to 5 above shall apply equally to pollution from land-based sources transported by the atmosphere wherever applicable and subject to the conditions specified in paragraph 1 of this Annex.

ANNEX IV :CRITERIA FOR THE DEFINITION OF BEST AVAILABLE TECHNIQUESAND BEST ENVIRONMENTAL PRACTICE

A. BEST AVAILABLE TECHNIQUES

1. The use of the best available techniques shall aim at preventing or minimizing the environmental impacts along all stages of life cycle of products and keeping as long as possible the value of products, materials and resources in the economy, minimizing the generation of waste.
2. The term “best available techniques” means the latest stage of development (state of the art) of processes, of facilities or of methods of operation which indicate the practical suitability of a particular measure for preventing and, where is not practicable, reducing discharges, emissions and waste. In determining whether a set of processes, facilities and methods of operation constitute the best available techniques in general or individual cases, special consideration shall be given to:
(a) comparable processes, facilities or methods of operation which have recently been successfully tried out;
(b) technological advances and changes in scientific knowledge and understanding;
(c) the economic feasibility of such techniques;
(d) time limits for installation in both new and existing plants;
(e) the nature, effects and volume of the discharges and emissions concerned;
(f) the commissioning dates for new or existing installations;
(g) the consumption and nature of raw materials used in the process and its energy efficiency;
(h) the need to prevent or reduce the overall impact of the releases to the environment and the risks to it;
(i) the need to prevent accidents and to minimize their consequences for the environment;
(j) the need to ensure occupational health and safety at workplaces.
(k) the need to use non-toxic substances in view of facilitating non-toxic waste streams to facilitate recovery and recycling
(l) the need to keep material and products in use as long as possible

3. It therefore follows that what is "best available techniques" for a particular process will change with time in the light of technological advances, economic and social factors, as well as changes in scientific knowledge and understanding.
4. If the reduction of discharges and emissions resulting from the use of best available techniques does not lead to environmentally acceptable results, additional measures have to be applied.
5. "Techniques" include both the technology used and the way in which the installation is designed, built, maintained, operated and dismantled.

B. BEST ENVIRONMENTAL PRACTICE

6. The term "best environmental practice" means the application of the most appropriate combination of environmental control measures and strategies to prevent and control pollution, to design out waste and pollution, to keep products and material in use and to regenerate natural systems. In making a selection for individual cases, at least the following graduated range of measures should be considered:
(a) the provision of information and education to the public and to users about the environmental consequences of choice of particular activities and choice of products, their use and ultimate disposal;
(b) the development and application of codes of good environmental practice, which cover all aspects of the activity in the product's life;
(c) the mandatory application of labels informing users of environmental risks related to a product, its use and ultimate disposal;
(d) saving resources, including energy;
(e) making collection and disposal systems as well as reuse centres available to the public;
(f) avoiding the use of hazardous substances or products and the generation of hazardous waste;
(g) establishing processes (i.e., industrial symbiosis) by which wastes, or by-products of an industry or industrial process become the raw materials for another
(h) the application of economic instruments to activities, products or groups of products;
(i) establishing a system of licensing, involving a range of restrictions or a ban;
(j) the use of eco-labels, eco-design and eco-innovation to identify products proven to be environmentally sound;
(k) establishing collaboration along the value chain in order to ensure that the origin and value of raw materials remain traceable when closing the loop;
7. In determining what combination of measures constitute best environmental practice, in general or individual cases, particular consideration should be given to:
(a) the environmental hazard of the product and its production, use and ultimate disposal;
(b) the substitution by less polluting activities or substances;
(c) the scale of use;
(d) the potential environmental benefit or penalty of substitute materials or activities;
(e) advances and changes in scientific knowledge and understanding;
(f) time limits for implementation;
(g) social and economic implications;
(h) the potential for keeping material and resources in use (e.g., through product services systems)
8. It therefore follows that best environmental practice for a particular source will change with time in the light of technological advances, economic and social factors, as well as changes in scientific knowledge and understanding.
9. If the reduction of inputs resulting from the use of best environmental practice does not lead to environmentally acceptable results, additional measures have to be applied and best environmental practice redefined.

C. GENERAL PREVENTION MEASURES RELATING TO BEST AVAILABLE TECHNIQUES AND BEST ENVIRONMENTAL PRACTICES

10. Priority should be given to the application of BAT and implementation of BEP to the sectors and categories of substances listed in Annex.

Appendix 2

Proposals for Updating the Annex to the Dumping Protocol

DUMPING PROTOCOL TO THE BARCELONA CONVENTION[4]

ANNEX

The factors to be considered in establishing criteria governing the issue of permits for the dumping of matter at sea taking into account Article 6 include:

A. CHARACTERISTICS AND COMPOSITION OF THE MATTER

1. Total amount and average compositions of matter dumped (e.g. per year).
2. Origin and form (e.g. solid, sludge, liquid, or gaseous within the matter, e.g. gases in sediments, or any mixture of these forms).
3. Properties: physical (e.g. solubility and density), chemical and biochemical (e.g. oxygen demand, nutrients) and biological (e.g. presence of viruses, bacteria, yeasts, parasites, invasive species).
4. Toxicity including but not limited to, trace metals, organohalogens, organosilicons, biocides (e.g. TBT), petroleum hydrocarbons, or other toxic substances, and as their mixtures.
5. Persistence: physical, chemical and biological.
6. Accumulation and biotransformation in biological materials and sediments including but not limited to, trace metals, organohalogens, organosilicons, biocides (e.g. TBT) or other toxic substances.
7. Susceptibility to physical, chemical, and biochemical changes and interaction in the aquatic environment with other dissolved organic and inorganic materials.
8. Probability of production of taints or other changes reducing marketability of resources (fish, shellfish, etc.)
9. Presence of marine litter/debris (e.g. plastic materials, micro-litter, etc.).

B. CHARACTERISTICS OF DUMPING SITE AND METHOD OF DEPOSIT

1. Location of the dumping site (e.g. coordinates, depth and distance from the coast), location/distance in relation to other amenities, values and other uses of the sea in the areas under consideration (e.g. amenity areas, spawning, nursery and fishing areas, marine protected areas and exploitable resources).
2. Rate of disposal per specific period (e.g. quantity per day, per week, per month).
3. Methods of packaging and containment, if any.
4. Initial dilution achieved by proposed method of release, particularly the speed of the ship.
5. Physical, chemical and biological characteristics of the water-column and the seabed, including:
a) Dispersal characteristics (e.g. effects of currents, tides and wind on horizontal transport and vertical mixing).
b) Water characteristics, physical, chemical and biological (e.g. temperature, pH, salinity, turbidity, transparency, stratification, oxygen indices of pollution-dissolved oxygen (DO), chemical oxygen demand (COD), biochemical oxygen demand (BOD5), nitrogen present in organic and mineral form, including suspended matter, other dissolved gases, organic carbon, other nutrients (phosphate and silicate) and productivity).
c) Bottom characteristics (e.g. substrate, topography/morphology, geochemical and geological characteristics and biological productivity).
d) Levels of underwater noise, particularly in relation to sensitive resources (e.g. cetaceans and pinnipeds, etc.)
6. Existence and effects of other dumpings which have been made in the dumping area (e.g. heavy metal background reading and organic carbon content).
7. Assessment of the constituent fluxes associated with dumping in relation to existing fluxes of substances in the marine environment.
8. Consideration of the physical characteristics of the waste proposed for disposal in relation to the site characteristics and waste assessment.

---

[4] Gray highlighted text reflects changes introduced to update the annex

9. Assessment of potential effects of dumping in the selected site(s) using*, inter alia*, modelling tools and cumulative effects of other activities in the same maritime sector, taking into consideration C.1, C.2 and C.3 under "Section C: General Considerations and Conditions".
10. When issuing a permit for dumping, the Contracting Parties shall endeavour to determine whether an adequate scientific basis exist for assessing the consequences of such dumping in the area concerned, in accordance with the foregoing provisions and taking into account seasonal variations. If it is accepted that a permit can be issued, then a suitable field monitoring programme may be developed/implemented, where appropriate.

C. GENERAL CONSIDERATIONS AND CONDITIONS
1. Possible effects on amenities (e.g. presence of floating or stranded material, turbidity, objectionable odor, discoloration and foaming).
2. Possible effects on marine life, fish and shellfish culture, fish stocks and fisheries, seaweed harvesting and culture, as well as effect on local communities living near islands or near marine protected areas.
3. Possible effects on other uses of the sea (e.g. impairment of water quality for industrial use, such as desalination plants, underwater corrosion of structures, interference with ship operations from floating materials, interference with fishing, mariculture, or navigation through deposit of waste or solid objects on the sea floor and protection of areas of special importance for scientific or conservation purposes).
4. Consideration of possible waste reduction/prevention techniques at source including: a) product reformulation; b) clean production technologies; c) process modification; d) input substitution; e) and on-site, closed-loop recycling.
5. Consideration of the following hierarchy of waste or other matter management options: re-use; off-site recycling; destruction of hazardous constituents; treatment to reduce or remove the hazardous constituents; disposal on land and in water.
6. The practical availability of alternative land-based methods of treatment, disposal or elimination or of treatment to render the matter less harmful for sea dumping.
7. Economic and operational feasibility.

Appendix 3

Regional Plan on Urban Wastewater Treatment in the Framework of Article 15 of the LBS Protocol

ARTICLE I
Definition of Terms

For the purpose of this Regional Plan for Urban Wastewater Treatment; hereinafter referred to as the "Regional Plan":

a) "Agglomeration" means an area where the population and/or economic activities are sufficiently concentrated for urban wastewater to be collected and conducted to an urban wastewater treatment plant or to a final discharge point;
b) "Appropriate treatment" means treatment of urban wastewater by any process and/or disposal system which after discharge allows the receiving waters to meet the relevant quality objectives;
c) "Aquifer" is an underground rock formation or sedimentary deposit porous enough to hold water that can be used to supply wells;
d) "Aquifer recharge" is the process of water infiltration by rainfall or other surface water into the ground. Groundwater recharge or deep percolation is a hydrologic process, whereby water moves downward from surface water to groundwater;
e) "Best Available Techniques (BAT)" as defined in Annex IV for the Land-Based Source and Activities (LBS) Protocol;
f) "Best Environmental Practice (BEP)" as defined in Annex IV for the Land-Based Source and Activities (LBS) Protocol;
g) "Biochemical Oxygen Demand (BOD5)" Amount of oxygen needed for the biochemical oxidation of the organic matter to carbon dioxide in 5 days;
h) "Collecting system" means a system of conduits which collects and conducts urban wastewater;
i) "Contaminants of Emerging Concern (CEC)" include several types of chemicals: persistent organic pollutants (POPs), pharmaceuticals and personal care products (PPCPs), including a wide suite of human prescribed drugs, veterinary medicines such as antimicrobials, antibiotics, anti-fungal, growth promoters and hormones; endocrine-disrupting chemicals (EDCs), including synthetic estrogens and androgens, nanomaterials such as carbon nanotubes or nano-scale particulate titanium dioxide, of which little is known about either their environmental fate or effects;
j) "Domestic wastewater" means wastewater from residential settlements and services which originates predominantly from the human metabolism and from household activities;
k) "Emission Limit Value (ELV)" means the maximum allowable concentration of a pollutant in an effluent discharged to the environment;
l) "Good Environmental Status": Concentrations of nutrients in the euphotic layer are in line with prevailing physiographic, geographic and climate conditions;
m) "Industrial wastewater" means any wastewater which is discharged from premises used for carrying on any trade or industry, other than domestic wastewater and run-off rainwater;
n) "Managed aquifer recharge (MAR)" is defined as the intentional recharge of water to aquifers for subsequent recovery or environmental benefit;
o) "One (1) population equivalent (p.e.)" means the organic biodegradable load having a five-day biochemical oxygen demand (BOD5) of 60 grams of oxygen per day. For the purpose of this regional plan, the load expressed in p.e. shall be calculated on the basis of the maximum

average weekly load entering the treatment plant during the year, excluding unusual situations such as those due to heavy rain;

p) "Primary treatment" means treatment of urban wastewater by a physical and/or chemical process involving settlement of suspended solids, or other processes in which the BOD5 of the incoming wastewater is reduced by at least 20 percent before discharge and the total suspended solids of the incoming wastewater are reduced by at least 50 percent;

q) "Reclaimed water" urban wastewater that has been treated to meet specific water quality criteria with the intent of being used for a range of beneficial purposes;

r) "Secondary treatment" means treatment of urban wastewater by a process generally involving biological treatment with a secondary settlement or other process so that the treatment results in a minimum reduction of the initial load of 70 to 90 percent of BOD5;

s) "Tertiary treatment" means treatment of urban wastewater by processes generally involving physical, chemical, biological and other procedures so that the treatment results in reduction of phosphorus and nitrogen, as well as disinfection;

t) "Urban wastewater" means the domestic wastewater or the mixture of domestic wastewater with industrial wastewater and/or run-off rainwater;

u) "WEFE" means Water – Energy – Food – Ecosystem Nexus;

v) "Wastewater Treatment Plant (WWTP)" means systems used to treat urban wastewater using physical, chemical and/or biological techniques.

ARTICLE II
Scope and Objective

1. The area to which the Regional Plan applies is the area defined in accordance with Article 3 of the LBS Protocol, consisting of the Mediterranean Sea Area as defined in Article 1 of the Convention; the hydrologic basin of the Mediterranean Sea Area; waters on the landward side of the baselines from which the breadth of the territorial sea is measured and extending, in the case of watercourses, up to the freshwater limit; brackish waters, coastal salt waters including marshes and coastal lagoons; and ground waters communicating with the Mediterranean Sea.

2. The Regional Plan shall apply to the collection, treatment, reuse and discharge of urban wastewaters and the pre-treatment and discharge of industrial wastewater from certain industrial sectors.

3. The objective of the Regional Plan on Urban Wastewater Treatment is to protect the coastal and marine environment and human health from the adverse effects of the above mentioned wastewater direct and or indirect discharges, in particular regarding adverse effects on the oxygen content of the coastal and marine environment and eutrophication phenomena as well as promote resource water and energy efficiency.

ARTICLE III
Preservation of Rights

4. The provisions of this Regional Plan shall be without prejudice to stricter provisions respecting the management of urban wastewater treatment plants contained in other existing or future national, regional or international instruments or programs.

ARTICLE IV
Guiding Principles

5. The Regional Plan measures are formulated to ensure the application of the following principles:
   i. Effective reclamation and reuse of treated wastewater is promoted as a means for water resource conservation and efficiency to effectively address regional water scarcity;
   ii. Wastewater collection and treatment systems incorporate aspects related to climate change impacts in the design and operation phases, including extreme hydrological patterns and their impact on influent wastewater;
   iii. Wastewater treatment processes promote energy efficiency and water savings, and integrate renewable energy alternatives to the extent possible in accordance with BAT and BEP;
   iv. Industrial wastewater is treated to the extent possible on site. Industrial wastewater entering collecting systems and WWTPs are subject to pre-treatment, if necessary, in order to (a) protect the collecting systems and the treatment plant; (b) ensure that the operation of the WWTP and the treatment of the sludge are not impeded; and (c) ensure that discharge effluents do not adversely affect the Mediterranean marine environment, particularly for priority substances, contaminants of emerging concern which are harmful to the receiving waters and cannot be treated in urban WWTPs;
   v. For the purpose of this Regional Plan, WEFE nexus is incorporated into the design phase of WWTPs with the aim to promote energy efficiency and reuse of reclaimed wastewater;
   vi. Selection of treatment technologies takes into consideration investment and operational costs of the treatment technology and the ability to pay by beneficiaries in order to ensure sustainable and reliable quality-treated wastewater.

ARTICLE V
Measures

I. Collection and treatment of urban wastewater

6. The Contracting Parties shall ensure that all agglomerations are provided with collecting systems for urban wastewater as follows:
   i. [At the latest by 2025] for those with a population equivalent (p.e.) of more than 15,000;
   ii. [At the latest by 2035 [2030]] for those with a population equivalent (p.e.) between 2000 and 15,000.

7. The Contracting Parties shall set emission limit values for discharge of treated effluents from WWTPs upon implementation of necessary measures. To this aim, the Contracting Parties shall adopt at the latest by [2025] the emission limit values as provided for in Annex I for the following categories:
   i. Discharge of effluents from urban wastewater treatment plants to the environment (Annex I.A).
   ii. Reuse of reclaimed wastewater for agriculture irrigation Annex I.B).
   iii. Discharge of industrial wastewater into collecting systems and urban wastewater treatment plants (Annex I.C).

8. The Contracting Parties may approve stricter emission limit values than those provided in Appendix I considering the characteristics of receiving/recipient environment.

9. The Contracting Parties shall ensure that prior to discharge, treated wastewater from urban WWTPs meets the following requirements [by 2035 [2030] at the latest]: [5]
   i. All discharges from agglomerations attributed to a population size of more than 15,000 p.e. are subject to the extent possible to tertiary treatment provided that the Good Environmental Status (GES) of the recipient environment is maintained.
   ii All discharges from agglomerations attributed to a population size of between 2000 and 15,000 p.e. are subject to the extent possible to secondary treatment provided that the Good Environmental Status (GES) of the recipient environment is maintained.

10. The Contracting Parties shall promote to the extent possible nature-based solutions for small agglomerations of less than 2000 p.e. with a focus on constructed wetlands where applicable.

11. The Contracting Parties shall ensure that urban wastewater treatment plants, built to comply with the requirements of Articles 7 and 8, are designed, constructed, operated and maintained to ensure sufficient performance under normal local climatic conditions.

12. The Contracting Parties shall ensure that WWTPs are designed to account for:
   i. Seasonal variations of loads including from touristic activities;
   ii. Volume and characteristics of the local municipal wastewater; and
   iii. Limitation of pollution of receiving water (taking into consideration, inter alia, Contaminants of Emerging Concern).

13. The Contracting Parties shall implement measures for:
   i. Segregating collecting systems for storm water and municipal wastewater, if technically and economically feasible;
   ii. Preventing or if not possible minimizing sewage and wastewater treatment plants' overflow due to rainwater penetration and flooding;
   iii. Addressing impacts of points of discharge of treated wastewater so as to minimize effects on receiving waters;
   iv. Adopting tools for conservation of surface water runoff in built environment; and
   v. Reducing pollutant loads and litter in storm water runoff from municipal and industrial sources.

II. Reclamation and reuse of wastewater

14. The Contracting Parties shall promote the reuse of reclaimed wastewater. To this aim, the Contracting Parties shall:

---

[5] *Study reservation by Italy, Spain, Malta and France to be clarified by the MAP Focal points Meeting. France indicates that "it is not coherent to talk about "population" and then to express it in terms of "population equivalents". France proposes in an email communicated to the Secretariat on 30 June 2021 rewriting of this paragraph as follows:*
The Contracting Parties shall ensure that prior to discharge, treated wastewater from urban WWTPs meets the following requirements [by 2035 [2030] at the latest]:
i. All discharges from agglomerations over than 15,000 p.e. are subject to the extent possible to tertiary treatment provided that the Good Environmental Status (GES) of the recipient environment is maintained.
ii. All discharges from agglomerations of size of between 2000 and 15,000 p.e. are subject to the extent possible to secondary treatment provided that the Good Environmental Status (GES) of the recipient environment is maintained.

i. Ensure that treatment technologies and additional treatments for reclaimed wastewater meet the emission limit values for reuse of reclaimed wastewater as provided for in Annex I.B.
ii. Implement wastewater reuse systems that include, inter alia:
    a) Storage and distribution systems for reuse of reclaimed wastewater effluents in agriculture;
    b) Recharge methods in case of managed aquifer recharge strictly complying with Annex II Guiding Principles.

III. Industrial wastewater discharge

15. By [2025 at the latest], the Contracting Parties shall ensure that the competent authority or appropriate body adopt emission limit values appropriate to the nature of industry discharging industrial effluents to collecting systems connected to urban WWTPs.

16. By [2035 at the latest], the Contracting Parties shall ensure that industrial wastewater discharged into collecting systems and urban WWTPs shall meet, as a minimum, the emission limit values set in Annex I.C.

IV. Monitoring

17. The Contracting Parties shall take measures to ensure regular monitoring in accordance with general elements and monitoring frequencies requirements as provided in Appendix III of the Regional Plan:
    i. Discharges from urban wastewater treatment plants to verify compliance with the requirements.
    ii. Receiving waters subject to discharges from urban wastewater treatment plants.
    iii. Quality of reclaimed wastewater discharged from treatment plants for beneficial use.
    iv. Discharged industrial effluents to collecting systems including substances harmful to receiving waters, sewerage networks and urban wastewater treatment plants.

ARTICLE VI
Technical Assistance, Transfer of Technology and Capacity Building

18. For the purpose of facilitating the effective implementation of Article V of this Regional Plan, the Contracting Parties collaborate to implement, exchange and share best practices directly or with the support of the Secretariat including BAT, BEP, sustainable consumption and production, circular economy, resource efficiency, WEFE Nexus in the design, construction, operation and maintenance of the urban wastewater treatment plants in the context of Integrated Water Resources Management. To this aim, the Contracting Parties also collaborate in preparing and implementing common technical guidelines.

ARTICLE VII
Timetable for Implementation

19. The Contracting Parties shall implement the measures included in this Regional Plan as per the timelines associated with these measures.

ARTICLE VIII
Reporting

20. The Contracting Parties shall report on implementation of measures stipulated in this Regional Plan in line with the reporting requirement and timelines provided in Article 26 of the Convention and Article 13, paragraph 2(d) of the LBS Protocol.

ARTICLE IX
Entry into Force

21. The present Regional Plan shall enter into force and become binding on the 180th day following the day of notification by the Secretariat in accordance with Article 15, paragraphs 3 and 4, of the LBS Protocol.

ANNEX I.A: Emission Limit Values for discharge of effluents from urban wastewater treatment plants to the environment

Table 1: Emission limit values for discharge of urban wastewater effluents to the environment *

Parameter	Unit	Emission limit values
BOD_5	mg/L	25
Total phosphorous	mg/L	2
Total Nitrogen	mg/L	40
Arsenic (As)	mg/L	0.5
Cadmium (Cd)	mg/L	0.025
Chlorine residual	mg/L	0.3
Chromium (Cr)	mg/L	0.25
COD	mg/L	125
Copper (Cu)	mg/L	0.5
Cyanide	mg/L	0.01
Lead (Pb)	mg/L	0.04
Mercury (Hg)	mg/L	0.0025
Mineral Oil	mg/L	1.5
Nickel	mg/L	0.25
pH	pH unit	6 to 9
Phenol	mg/L	0.15
Total Suspended Solids (TSS)	mg/L	30
Zinc	mg/L	1
Total Hydrocarbons	mg/L	10

* *Different emission limit values, including for other parameters, may be adopted further to a risk-based assessment provided that there is no negative impact on the recipient environment*

Emission limit values (ELVs) for other emerging pollutants may be set considering the following factors:

- Setting thresholds for toxicity of effluent streams discharged to the environment to prevent toxicity to aquatic organisms;
- Determination of the minimum percentage of biodegradability of the effluent streams (at least 80%) to achieve minimum accumulation in the ecosystem and losses of habitats and biodiversity; and
- Identification of potential microplastic sources and adoption of related policy and methodology further to state of the art on related research on this topic.

ANNEX I.B: Emission limit values for reuse of reclaimed wastewater for agriculture irrigation

Classes definitions for reclaimed wastewater for reuse in agriculture irrigation:

Class A – **All food crops**, including crops eaten raw when reclaimed wastewater comes into direct contact with edible parts of the crop, and irrigation of root crops.

Class B - **Processed food crops**: crops which are intended for human consumption not to be eaten raw but after a treatment process and **Non-food crops**: crops which are not intended for human consumption.

Table 2: Emission limit values for reclaimed wastewater use in agricultural irrigation according to Class definition

Parameter	Limit values for reclaimed water quality class for effluent reuse in agricultural irrigation *	
	Class A	Class B
BOD5	≤10 mg/L	25 mg/L or reduction of the influent load of 70% to 90%.
COD**	100 mg/L	125 mg/L
Escherichia coli	≤10 cfu/100 ml	≤100 cfu/100 ml
Fecal Coli	≤10 cfu/100ml or below detection limit	≤100 cfu/100ml
Intestinal nematodes (helminth eggs)	≤1 egg/l	≤1 egg/l
Legionella spp	≤1,000 cfu/l	≤1,000 cfu/l
Total Suspended Solids (TSS)	≤10 mg/L	35 mg/L or reduction of influent load of 90%.
Turbidity	≤5 NTU	None
Parameters applicable to both Classes (A and B)		
Total Nitrogen	25	
Total phosphorous	5	
Sodium - Na	150	
Chlorides - Cl	250	
Boron - B	0.5	
Heavy metals		
Cadmium - Cd	0.01	
Chromium - Cr	0.1	
Copper - Cu	0.2	
Mercury - Hg	0.002	
Nickel - Ni	0.2	
Lead - Pb	0.1	
Zinc - Zn	0.5	
pH	6.5-8.5	
Additional heavy metals		
Aluminium - Al	1 to 5	
Arsenic - As	0.1	
Beryllium - Be	0.1	
Cobalt - Co	0.05	
Iron - Fe	2	
Lithium - Li	2.5	
Manganese - Mn	0.2	

Parameter	Limit values for reclaimed water quality class for effluent reuse in agricultural irrigation *	
	Class A	Class B
Molibdenum - Mo	0.01	
Selenium - Se	0.02	
Vanadium - V	0.1	

* *Different emission limit values, including for different parameters, may be adopted further to a risk-based assessment provided that the total loads do not affect the recipient environment and human health*

ANNEX I.C: Emission limit values for discharge of industrial wastewater into collecting systems and urban wastewater treatment plants

Industrial wastewater entering collecting systems and urban wastewater treatment plants shall be subject to pre-treatment as required in order to:

- Protect the health of staff working in collecting systems and treatment plants.
- Ensure that collecting systems, WWTP and associated equipment are not damaged.
- Ensure that the operation of the WWTP and the treatment of sludge are not impeded.
- Ensure that discharges from the treatment plants do not adversely affect the environment or prevent receiving water from complying with other regulatory requirements.
- Ensure that sludge can be treated and disposed of safely in an environmentally acceptable manner.

Table 3: Emission limit values (ELV) for industries to discharge their effluents to collecting systems and Urban WWTPs which will not damage wastewater treatment processes and does not affect the recipient environment

Parameter	Unit	Limit values for effluent discharge *
Aluminium - Al	mg/L	25
BOD5	mg/L	COD concentration not to exceed four times BOD concentration
Fluoride – F	mg/L	6
Sodium - Na	mg/L	230
Phenols	mg/L	3
Total O&G	mg/L	250
Arsenic - As	mg/L	0.1
Benzene	mg/L	0.05
Beryllium - Be	mg/L	0.5
Cadmium - Cd	mg/L	0.1
Chloride - Cl	mg/L	430
Chlorine	mg/L	0.5
Chromium - Cr	mg/L	0.5
Cobalt - Co	mg/L	1
COD	mg/L	2000
Copper - Cu	mg/L	0.5 to 1
Cyanide	mg/L	0.2 to 0.5
AOX	mg/L	1
Lead - Pb	mg/L	0.5
Lithium - Li	mg/L	0.3
Manganese - Mn	mg/L	1
Mercury - Hg	mg/L	0.05
Mineral Oil	mg/L	20
Molybdenum - Mo	mg/L	0.15

Parameter	Unit	Limit values for effluent discharge *
Nickel - Ni	mg/L	0.5
Total phosphorous - (TP)	mg/L	30
pH	units	6.0-10.0
Polyphenols	mg/L	100
Selenium - Se	mg/L	0.05
Total Dissolved Solids (TDS)	mg/L	3,500
Temp	C°	40° Celsius
Tin - Sn	mg/L	2
Total Nitrogen - (TN)**	mg/L	15-30
Total Hydrocarbons	mg/L	20
Toxicity to fish eggs (Tegg)		2
Total Suspended Solids (TSS)	mg/L	1000
Vanadium - V	mg/L	0.5
Volatile halogenated hydrocarbons (VHHC)	mg/L	0.1***
Zinc - Zn	mg/L	3

** The adoption and implementation of the ELVs shall respond to the respective industries. Different emission limit values, including for different parameters, may be adopted further to a risk-based assessment also in line with national regulations and procedures in collaboration with the operators of treatment plants. ELV may be increased for small industries discharging to the collecting system when (i) the plant uses BAT and (ii) the effects of the discharged effluent on the collecting system and the WWTP are negligible.*

*** Total nitrogen as the sum of ammonia nitrogen, nitrite nitrogen and nitrate nitrogen*

**** Volatile halogenated hydrocarbons - sum of trichloroethene, tetrachloroethene, 1,1,1-trichloroethane, dichloromethane - calculated as chlorine*

ANNEX II: Guiding principles on reuse of reclaimed wastewater for aquifer recharge

Managed aquifer recharge (MAR) is defined as the intentional recharge of water to aquifers for subsequent recovery or environmental benefit. The purposes for undertaking managed aquifer recharge are as follows:

- Establish saltwater intrusion barriers in coastal aquifers.
- Provide storage for the recharged water for subsequent retrieval and reuse.
- Maintain groundwater dependent terrestrial and aquatic ecosystems.
- Dilute saline or polluted aquifers.
- Control or prevent ground subsidence.

Recharge methods:

1. **Surface spreading** – a method of recharge whereby the water moves from the land surface to the aquifer by infiltration and percolation through the vadose zone. When used as a recharge method, adverse effects to the soil and related dependent ecosystems should be avoided.
2. **Direct injection** – a method of directly pumping/ injecting water into the groundwater zone. Direct discharges of pollutants into groundwater is not allowed.

Risk assessment:

Health and environmental risk assessment is needed to define minimum quality requirements. The assessment will address appropriate health protection; provision of public confidence in reuse practices; avoiding adverse effects on groundwater, soils and related dependent ecosystems. The overall levels of health protection should be comparable for different water-related exposures (i.e. drinking water, and reclaimed water for irrigation of food crops).

ANNEX III: Monitoring frequencies of pollutants discharged directly to the environment; or destined for reuse in agriculture; or discharged from industrial facilities to collecting systems

Monitoring the treated effluents discharge from urban WWTPs is used to determine compliance with emission limit values for discharge to the environment; to reuse in agriculture irrigation; or for aquifer recharge (Annex I.A, Annex I.B, Annex I.C).

Monitoring frequencies need to be sufficient to characterize the effluent quality and to detect events of noncompliance, considering the need for data and, as appropriate, the potential cost. Monitoring frequency should be determined on a case-by-case basis, consider the variability of the concentration of various parameters. A highly variable discharge should require more frequent monitoring than a discharge that is relatively consistent over time (particularly in terms of flow and pollutant concentration).

Frequency requirements may be reduced based on a demonstration of excellent performance. Facilities can demonstrate good performance by meeting a set of compliance and enforcement criteria and demonstrating their ability to discharge pollutants below the necessary levels consistently.

The sampling frequency for monitoring of the discharge effluents may be defined to the extent possible as per the tables below:

Table 4: Recommended sampling frequency for treated effluents at the point of discharge

Parameter	Monitoring Frequency		Grab / Composite sample
	Large UWWTP (more than 5,000 p.e.)	Small UWWTP (less than 5,000 p.e.)	
Heavy metals	Once a quarter	Once a year	Composite sample
EC + pH	Continuous monitoring	Once a month	Grab samples
BOD, COD	Once a week	Once a month	Composite sample
Turbidity	Once a week	Once a month	Grab samples
TSS	Every two weeks	Once a month	Composite sample
Nutrients (N, P, K)	Once a week	Once a month	Composite sample
Pathogens	Every two weeks	Once a month	Grab samples
Mineral Oil, Phenol, Total Hydrocarbons	Once a month	Once a month	Grab samples

Table 5: Minimum frequency for reclaimed wastewater monitoring for agricultural irrigation

Parameter	Monitoring Frequency for reclaimed wastewater quality classes	
	Class A	Class B
BOD	Once a week	Once a month
TSS	Once a week	Once a month
Turbidity	Continuous	Once a month
Escherichia coli	Once a week	Twice a month
Legionella spp (when applicable)	Once a week	Once a week
Intestinal nematodes (when applicable)	Twice a month or frequency determined according to the number of eggs in wastewater	
Heavy metals	Once a quarter	Once a year
EC and pH	Continuous monitoring	Once a month
Nutrients (N, P, K)	Once a week	Once a month

Table 6: Recommended sampling frequency per year for industrial wastewater at the point of discharge to the collecting systems and urban WWTP

No.	Industrial Activities	Sampling frequency (*)
1	Wastewater containing mineral oil	4 Once every three months
2	Domestic and communal wastewater (function halls, restaurants, shopping malls, hotels etc.)	4 Once every three months
3	Food Sector - Animal and vegetable products	4 Once every three months
4	Food Sector - Meat industry & Fish processing	4 Once every three months
5	Textile sector - manufacturing and finishing	4 Once every three months
6	Metals production and processing	6 Once every two months
7	Laundry Facilities	4 Once every three months
8	Gas stations	4 Once every three months
9	Agriculture: chicken farms, pig farms, fish farms, etc.	4 Once every three months
10	Leather production, fur processing, leather fibreboard manufacturing	4 Once every three months
11	Waste and wastewater management	Waste – 4 Once every three months Hazardous waste – 6 Once every two months
12	Production of printing blocks, publications and graphic-arts products	4 Once every three months
13	Chemical industry including chemicals, pharmaceuticals, fertilizers, pesticides, detergents, solvents, petrochemicals, Cosmetic, plastic etc.	Water consumption: - less than 5,000 m^3/year – 6 once every two months - higher than 5,000 m^3/year – 12; once per a year
14	Hospitals	4 Once every three months

* *The sampling rate should reflect the fluctuation of the effluent*

Appendix 4

Regional Plan on Sewage Sludge Management in the Framework of Article 15 of the LBS Protocol

ARTICLE I
Definition of Terms

For the purpose of this Regional Plan for the Sewage Sludge Management; hereinafter referred to as the "Regional Plan":

(a) "Anaerobic digestion" is the biological conversion of organic matter to biogas and residual solids at temperatures between 20°C and about 40°C, typically 37°C with a mean residence time of 15 to 30 days (Mesophilic) or that takes place between 49°C and 57°C (thermophilic);
(b) "Best Available Techniques (BAT)" as defined in Annex IV for the Land-Based Source and Activities (LBS) Protocol;
(c) "Best Environmental Practice (BEP)" as defined in Annex IV for the Land-Based Source and Activities (LBS) Protocol;
(d) "Biosolids" are organic-based materials from industrial or municipal wastewater sludge and their derived products, in the form of solids, semisolids, semi–liquids (pasty), and liquids which have been treated to meet specific standards, guidelines or requirements;
(e) "Collecting system" means a system of conduits which collects and conducts urban wastewater;
(f) "Composting" is the natural aerobic biological process, carried out under controlled conditions, which converts organic material into a stable humus-like product;
(g) "Domestic wastewater" means wastewater from residential settlements and services which originates predominantly from the human metabolism and from household activities;
(h) "Industrial wastewater" means any wastewater which is discharged from premises used for carrying on any trade or industry, other than domestic wastewater and run-off rainwater;
(i) "Primary sludge" is sludge from primary settling tanks, typically grayish and slimy in nature, and, in most of the cases, has an extremely offensive odor. Primary sludge can be readily digested under suitable conditions of operation;
(j) "Primary treatment" means treatment of urban wastewater by a physical and/or chemical process involving settlement of suspended solids, or other processes in which the BOD5 of the incoming wastewater is reduced by at least 20 percent before discharge and the total suspended solids of the incoming wastewater are reduced by at least 50 percent;
(k) "Secondary sludge (activated sludge)" is the sludge particles produced in raw or settled wastewater by the growth of organisms in aeration tanks in the presence of dissolved oxygen. The term activated comes from the fact that the particles are teeming with bacteria, fungi, and protozoa. Activated sludge is different from primary sludge in that the sludge particles contain many living organisms which can feed on the incoming wastewater;
(l) "Secondary treatment" means treatment of urban wastewater by a process generally involving biological treatment with a secondary settlement or other process so that the treatment results in a minimum reduction of the initial load of 70 to 90 percent of BOD5;
(m) "Sludge incineration (waste to energy)" is a two-step process involving drying and combustion after a preceding dewatering process, such as filters, drying beds, or centrifuges;
(n) "Tertiary treatment" means treatment of urban wastewater by processes generally involving physical, chemical, biological and other procedures so that the treatment results in reduction of phosphorus and nitrogen, as well as disinfection;
(o) "Urban wastewater" means the domestic wastewater or the mixture of domestic wastewater with industrial wastewater and/or run-off rainwater;
(p) "Wastewater Treatment Plant (WWTP)" means systems used to treat urban wastewater using physical, chemical and/or biological techniques.

ARTICLE II
Scope and Objective

1. The area to which the Regional Plan applies is the area defined in accordance with Article 3 of the LBS Protocol, consisting of the Mediterranean Sea Area as defined in Article 1 of the Convention; the hydrologic basin of the Mediterranean Sea Area; waters on the landward side of the baselines from which the breadth of the territorial sea is measured and extending, in the case of watercourses, up to the freshwater limit; brackish waters, coastal salt waters including marshes and coastal lagoons; and ground waters communicating with the Mediterranean Sea.
2. The Regional Plan shall apply to the treatment, disposal and use of sewage sludge from Urban Wastewater Treatment Plants.
3. The objective of the Regional Plan is to ensure effective reuse of beneficial substances and exploitation of energy potential of sewage sludge, while preventing harmful effects on human health and the environment.

ARTICLE III
Preservation of Rights

4. The provisions of this Regional Plan shall be without prejudice to stricter provisions respecting the management of sewage sludge from urban wastewater treatment plants contained in other existing or future national, regional or international instruments or programs.

ARTICLE IV
Guiding Principles

5. The Regional Plan measures are formulated to ensure the application of the following principles:
   i. Sewage sludge shall meet the required quality criteria suitable for its intended use or disposal;
   ii. Management alternatives are prioritized for beneficial use of sewage sludge in agricultural land applications in order to minimize landfilling and adverse environmental effects;
   iii. Since sewage sludge can have valuable agronomic properties reducing dependence on fertilizers, its application is encouraged in agriculture subject to adequate treatment and quality standards for human health and environment protection.
   iv. Sewage sludge can be used in other applications such as forests, mine reclamation sites, and other disturbed lands, parks, and golf courses, subject to adequate treatment and quality standards for human health and environment protection;
   v. Use of sewage sludge does not impair the quality of the soil and of agricultural products;
   vi. Use of sewage sludge in agriculture is regulated in such a way as to prevent harmful effects on soil, water bodies, vegetation, animals and humans;
   vii. Sewage sludge may be used as an alternative fuel; energy production; and for incineration and co-incineration and other proven applications.

ARTICLE V
Measures

I. <u>Treatment of sewage sludge</u>

6. The Contracting Parties shall ensure that all required sludge treatment processes are carried out in line with common agreed guidelines, in order to obtain treated sludge of quality suitable for their specific use in, inter alia:

i. Agricultural land application as a fertilizer or for land reclamation;
ii. Energy recovery; and
iii. Cement industry.

II. Agricultural use

7. For the application of sludge under specific conditions of land application, the Contracting Parties shall apply adequate treatment to limit pathogen contents in biosolids destined for agricultural applications. To this aim, the Contacting Parties shall set classes for sludge with limit values for pathogen contents for biosolids to ensure that use would not affect human health and the environment. The following two "biosolids classes" and corresponding limit values for pathogen content for biosolids are considered. [By 2025 at the latest, the Contracting Parties shall adopt Class A. Class B may be adopted where appropriate:]

i. Class 'A' biosolids suitable for use as fertilizer for agricultural crops having met the pathogen reduction requirements set in Table 1 by treatment processes that include a suitable combination of composting, heat drying, heat treatment, thermophilic anaerobic digestion, beta or gamma ray irradiation and pasteurization, or any other equivalent treatment technologies.
ii. Class 'B' biosolids suitable for use as fertilizer for non-food crops having met the pathogen reduction requirements set in Table 1 by treatment processes that include a suitable combination of aerobic digestion, composting, anaerobic digestion, lime stabilization and air drying, or any other equivalent treatment technologies.

Table 1: Limit values for pathogen content for biosolids classes

Class	Faecal Coliforms *(Escherichia coli)*	Salmonella sp.	Enterovirus*	Helminths ova*
Class A	< 1000 MPN/g DM *(< 1000 MPN/g DM)*	< 3 MPN/4 g DM	1 PFU/4 g DM**	1 viable/4 g DM
Class B	< 2,000,000 MPN/g DM*** *(< 200,000 MPN/g DM)*			

** These parameters may be included based on specific local conditions, and if monitored, lower frequencies may apply.*
*** PFU: Plaque Forming Unit*
*** MPN: Most Probable Number; DM: Dry Matter*
**** Geometric mean of seven samples*

8. The Contracting Parties shall apply adequate treatment to limit concentrations of heavy metals in biosolids destined for agricultural applications. To this aim, the Contacting Parties shall adopt limit values for heavy metals to ensure that use would not affect human health and the environment. The following limit values for heavy metals in biosolids (Table 2) and heavy metals in soil (Table 3) shall be adopted at the latest by 2025.

Table 2: Limit values for concentration of heavy metals in biosolids ($mg.kg^{-1}$ DS) *

Range**	Cadmium	Chromium	Copper	Mercury	Nickel	Lead	Zinc
Lower	20	1000	1000	16	300	750	2500
Upper	40	1500	1750	25	400	1200	4000

** Different emission limit values, including for other parameters, may be adopted further to a risk-based assessment if there is no negative impact on the recipient environment.*
*** To be defined based on local conditions including soil pH.*

Table 3: Limit values for concentrations of heavy metals in soil to which biosolids is applied ($mg.kg^{-1}$ DS) *							
Range**	Cadmium	Chromium	Copper	Mercury	Nickel	Lead	Zinc
Lower	1	100	50	1	30	50	150
Upper	3	150	140	1.5	75	300	300

** Different emission limit values, including for other parameters, may be adopted further to a risk-based assessment if there is no negative impact on the recipient environment*
*** To be defined based on local conditions including soil pH*

9. The Contracting Parties shall specify the conditions for use of sludge in its different states (stabilized, treated, untreated) taking into consideration the proximity of sludge application to various types of human activities and civil structure facilities/natural features. To this aim, the Contracting Parties agree to formulate a common guideline.

10. In the event that limit values set in Tables 1 to 3 cannot be met, the Contracting Parties shall apply alternative means to agricultural use including incineration and regulated landfilling ensuring in both cases, that there is no negative impact on the environment (particularly for water sources) and human health, and that disposal of sewage sludge in coastal areas is prohibited.

11. The Contracting Parties shall apply adequate treatment processes to reduce volatile organic compounds and diminish possible odor emissions in the different stages of sludge treatment, transport and application in agriculture and other suitable uses.

III. Sewage sludge use and energy/nutrient recovery

12. The Contracting Parties shall establish the required infrastructure for the implementation of the requirements of the applicable measures of this Regional Plan with regards to the use for agricultural land applications and/or for energy/nutrient recovery at the latest by 2035.

IV. Considerations for reducing impacts of climate change

13. The Contracting Parties shall reduce energy costs and increase water savings during treatment by using BAT and applying BEP including the use of alternative and renewable energy sources based on advanced technologies such as anaerobic digestion, pyrolysis/gasification, mass burning and other technologies.

14. The Contracting Parties shall implement technologies targeting energy efficient treatment of sludge such as pretreatment of sludge, solar drying, bio-drying, composting, etc.

15. The Contracting Parties shall promote implementation of adaptation measures for climate change protection including:
    i. Taking advantage of the biosolids as an important source of nutrients and organic matter;
    ii. Using biosolids as soil amendment to combat desertification; improve infiltration of water (precipitation or irrigation water); ensure better drainage in high rainfall areas; and decrease surface water runoff;
    iii. Increasing on-site carbon sequestration potential.

V. Monitoring

16. The Contracting Parties shall take measures to ensure monitoring of the quality of sewage sludge in the WWTP or after treatment outside the WWTP, whichever constitutes the last treatment process before use, with the aim of determining sludge class as provided for in Article IV of this Regional Plan, and accordingly, to select the adequate monitoring programmes to the extent possible as indicated in Table [4] on the frequency of monitoring for pollutants, pathogen

densities, and vector attraction reduction in sewage sludge. To this aim, the Contracting Parties collaborate to formulate common agreed technical guidelines on routine monitoring of treated sewage sludge.

Table 4: Frequency of monitoring for pollutants, pathogen densities, and vector attraction reduction in Sewage Sludge

Amount of biosolids [Dry matter] Tons per 365-day period	Tons per day	Frequency
> 0 to < 290	> 0 to < 0.80	Once per year
≥ 290 to < 1,500	≥ 0.80 to < 4.10	Once per quarter (4 times per year)
≥ 1,500 to < 15,000	≥ 4.10 to < 41	Once per 60 days (6 times per year)
≥ 15,000	≥ 41	Once per month (12 times per year)

ARTICLE VI
Technical Assistance, Transfer of Technology and Capacity Building

17. For the purpose of facilitating the effective implementation of the measures and monitoring obligations under Article V of this Regional Plan, the Contracting Parties are urged to consider the techniques provided for in this Plan and to exchange and share best practices directly or with the support of the Secretariat including BAT, BEP, sustainable consumption and production, circular economy, resource efficiency, WEFE Nexus in the design, construction, operation and maintenance of the urban wastewater treatment plants.

ARTICLE VII
Timetable for Implementation

18. The Contracting Parties shall implement the measures included in this Regional Plan as per the timelines associated with these measures.

ARTICLE VIII
Reporting

19. The Contracting Parties shall report on implementation of measures stipulated in this Regional Plan in line with the reporting requirement and timelines provided in Article 26 of the Convention and Article 13, paragraph 2(d) of the LBS Protocol.

ARTICLE IX
Entry into Force

20. The present Regional Plan shall enter into force and become binding on the 180th day following the day of notification by the Secretariat in accordance with Article 15, paragraphs 3 and 4, of the LBS Protocol.

Appendix 5

Draft Updated Regional Plan for Marine Litter Management in the Mediterranean in the Framework of Article 15 of the LBS Protocol

Part I – General provisions [6]

ARTICLE 1
Rationale for the Regional Plan

1. Marine litter may have significant implications for the marine and coastal environment at a global level. These impacts are environmental, economic, health and safety and cultural, rooted in our prevailing production and consumption patterns. The problem originates mostly from land-based activities and sea-based activities, as well as lack of governmental financial resources, general lack of understanding of the public's co-responsibility, and the optimisation of the application of legal enforcement systems could limit pollution.

2. The rationale for the preparation of this Regional Plan is to improve the quality of the marine and coastal environment in accordance with the provisions of the LBS Protocol and to achieve the goals set by the decisions of the 17th meeting of the Contracting Parties in 2012, Decision IG.20/4: "Implementing MAP ecosystem approach roadmap: Mediterranean Ecological and Operational Objectives, Indicators and Timetable for implementing the ecosystem approach roadmap" and Decision IG 20/10: "Adoption of the Strategic Framework for Marine Litter management," at the considerable lower cost than with the no action scenario.

ARTICLE 2
Area and Scope of Application

3. The area to which this Regional Plan applies is the area defined in Article 3 of the LBS Protocol paragraphs (a), (c) and (d).[7] The Regional Plan shall apply to discharges referred to in Article 4(a)[8] of the LBS Protocol and any operational discharge from ships, platforms and other man-made structures at sea.

ARTICLE 3
Definition of Terms

4. For the purpose of this Regional Plan:

   a) Abandoned, lost or otherwise discarded fishing gear or parts thereof (ALDFG) or *Derelict fishing gear (DFG)* are the collective terms for commercial and recreational fishing gear or

---

[6] *Text highlighted in gray reflects the updates undertaken to the Regional Plan compared to the 2013 version.*

[7] Article 3 of the LBS Protocol: Protocol Area:
The area to which this Protocol applies (hereinafter referred to as the "Protocol Area") shall be:
(a) The Mediterranean Sea Area as defined in article 1 of the Convention.
(c) Waters on the landward side of the baselines from which the breadth of the territorial sea is measured and extending, in the case of watercourses, up to the freshwater limit.
(d) Brackish waters, coastal saltwater including marshes and coastal lagoons, and ground waters communicating with the Mediterranean Sea.

[8] Article 4 of the LBS Protocol Application:
This Protocol shall apply: (a) To discharges originating from land-based point and diffuse sources and activities within the territories of the Contracting Parties that may affect directly or indirectly the Mediterranean Sea Area. These discharges shall include those which reach the Mediterranean Area, as defined in article 3(a), (c) and (d) of this Protocol, through coastal disposals, rivers, outfalls, canals, or other watercourses, including ground water flow, or through run-off and disposal under the seabed with access from land.

aquaculture-related items that have been abandoned, lost or otherwise discarded into the marine environment;

b) *Barcelona Convention* means the Convention for the Protection of the Marine Environment and the Coastal Region of the Mediterranean, 1995 hereinafter referred to as the Barcelona Convention;

c) *Best Available Techniques (BAT)* as defined in Annex IV for the Land-Based Source and Activities (LBS) Protocol;

d) *Best Environmental Practice (BEP)* as defined in Annex IV for the Land-Based Source and Activities (LBS) Protocol;

e) *Circular economy,* an approach contributing to Sustainable Consumption and Production patterns, refers to a system where products, materials and resources maintain their value and use in the economy, for as long as possible, thus minimizing waste by sharing, leasing, reusing, repairing, refurbishing, remanufacturing and recycling, instead of throw-away or take-make-dispose models;

f) *Extended Producer Responsibility* means a set of measures taken by Contracting Parties to ensure that producers of products bear financial responsibility or financial and organisational responsibility for the management of the waste stage of a product's life cycle;

g) *Fishing gear* means any item or piece of equipment that is used in fishing or aquaculture to target, capture or rear marine biological resources or that is floating on the sea surface, and is deployed with the objective of attracting and capturing or of rearing such marine biological resources;

h) *Garbage* includes all kinds of food, domestic and operational waste, all plastics, cargo residues, incinerator ashes, cooking oil, fishing gear, and animal carcasses generated during the normal operation of the ship and liable to be disposed of continuously or periodically. Garbage does not include fresh fish and parts thereof generated as a result of fishing activities undertaken during the voyage, or as a result of aquaculture activities;

i) *LBS National Action Plan* means the national action plans containing measures and timetables for their implementation developed by the Contracting Parties in accordance with Article 5 of the LBS Protocol as endorsed by the 14th and 19th meetings of the Contracting Parties with the view to implement the Strategic Action Programme (SAP-MED) to combat land-based sources in the Mediterranean adopted by the Contracting Parties in 1997 and UNEP/MAP's ecosystem approach-based ecological objectives on pollution and litter;

j) *LBS Protocol* means the Protocol for the Protection of the Mediterranean Sea against Pollution from Land-Based Sources and Activities, 1996, hereinafter referred to as the LBS Protocol;

k) *Leakage* means unintentional disposal of wastes into the marine environment;

l) *Lightweight plastic carrier bag* means a plastic carrier bag with a wall thickness below 50 microns;[9]

m) *Marine litter,* regardless of the size*,* means any persistent, manufactured or processed solid material, discarded, disposed of, or abandoned in the marine and coastal environment;

n) *Marine Litter monitoring* the long term, standardized measurement, observation and assessment of litter on beaches, in the water column including the sea surface and the seabed and in biota in order to determine litter types, quantities, sources and pathways and assess the effectiveness of measures and whether GES has been achieved by comparing with established baseline and threshold values;

o) *Microlitter* means the fraction of marine litter of less than 5 mm in size with a further division into *Large Micro Particles* (1-5 mm) and *Small Micro Particles* (<1 mm);

p) Microplastics, most commonly defined as manmade solid particles composed of mixtures of polymers and functional additives, smaller than 5 mm;

q) *Plastic* means a material consisting of a polymer, to which additives or other substances may have been added, and which can function as a main structural component of final products, with the exception of natural polymers that have not been chemically modified;[9]

r) *Primary microplastics* are tiny particles designed for direct commercial use (such as cosmetics, detergents and paints components), or for indirect use (such as pre-production pellets);

s) *Secondary microplastics* means the fraction of microplastics in the marine environment which results from the breakdown of larger plastic items into numerous tiny fragments due to mechanical forces and/or photochemical processes, as well as from other degradation sources such as water bottles, fibres in wastewater from washing clothes and particles of rubber lost from tyres due to normal wear;

t) *Single Use Plastics (SUPs):* means an item or product that is made wholly or partly from plastic and that is not conceived; designed or placed on the market to accomplish, within its life span, multiple trips or rotations by being returned to a producer for refill or re-used for the same purpose for which it was conceived;

u) *Waste* means substances or objects which are disposed of or are intended to be disposed of or are required to be disposed of by the provisions of national law.[9]

ARTICLE 4
Objectives and Principles

Objectives

5. The main objectives of the Regional Plan are to:

a) Prevent and reduce to the minimum marine litter pollution in the Mediterranean and its impact on ecosystem services, habitats, species (in particular the endangered species), public health and safety, as well as reduction of the socioeconomic costs it causes;

b) Remove to the extent possible already existent marine litter by using environmentally sound methods;

c) Ensure that the management of marine litter in the Mediterranean is performed in accordance with accepted international standards and approaches as well as those of relevant regional organizations and as appropriate in harmony with programmes and measures applied in other seas;

d) Enhance knowledge and understanding on marine litter and its impacts;

e) Support Contracting Parties in the development, implementation, and coordination of programmes for litter reduction, including National Action Plans (NAPs).

Principles

6. In implementing the Regional Plan, the Contracting Parties shall be guided by:

a) *Integration* by virtue of which marine litter management shall be an integral part of the solid waste management and other relevant strategies;

b) *Prevention* by virtue of which any marine litter management measure should aim at addressing the prevention of marine litter generation at the source;

---

[9] *Definition proposed by Malta and agreed by the Contracting Parties in email correspondences received by the Secretariat with no modifications or objections*

c) *Precautionary principle* by virtue of which where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation;

d) *Polluter-pays principle* by virtue of which the costs of pollution prevention, control and reduction measures are to be borne by the polluter, with due regard to the public interest;

e) *Ecosystem-based approach* by virtue of which the cumulative effects of marine litter on marine and coastal ecosystem, habitats and species with other contaminants and substances that are present in the marine environment should be fully taken into account;

f) *Public participation and stakeholder involvement*;

g) *Sustainable Consumption and Production* by virtue of which current unsustainable patterns of consumption and production must be transformed to sustainable ones that decouple human development from environmental degradation, in particular through the use of systemic approaches addressing environmental impacts along the entire value chain, including circular economy.

ARTICLE 5
Preservation of Rights

7. The provisions of this Regional Plan shall be without prejudice to stricter provisions respecting marine litter management measures contained in other existing national, regional or international instruments or programmes.

Part II – Measures and Operational Targets

ARTICLE 6
Coherence and Integration of Measures

8. The Contracting Parties shall make best effort that the measures provided for in Articles 7 to 10 are implemented, as specified in the respective articles, in a coherent manner to achieve good environmental status and relevant targets on marine litter. Various actors shall be involved in the development and implementation of agreed measures as provided for in Article 17.

ARTICLE 7
Integration of marine litter measures into the LBS National Action Plans (LBS NAPs)

9. The Contracting Parties in accordance with Article 5 of the LBS Protocol shall elaborate and implement, individually or jointly, as appropriate, national and regional action plans and programmes, containing measures and timetables for their implementation. In doing so, the Contracting Parties shall consider updating periodically the LBS NAPs to integrate marine litter in accordance with the provisions of this Regional Plan and other means to perform their obligations.

10. The LBS National Action Plan shall include:

a) Development and implementation of appropriate policy, legal instruments and institutional arrangements, including adequate management plans for solid waste also including those originating from sewer and storm water systems, which shall incorporate marine litter prevention and reduction measures

b) Monitoring and assessment programmes for marine litter;

c) Measures and targets to prevent and reduce marine litter;

d) Measures and targets to increase plastic waste collection and recycling;

e) Programmes of removal and environmentally sound disposal of existing marine litter according to the national legislation about management of this kind of waste; and

f) Awareness raising and education programmes.

ARTICLE 8
Legal and Institutional Aspects

11. For the purpose of implementing the Regional Plan, the Contracting Parties shall adopt, as appropriate, the necessary legislation and/or establish adequate institutional arrangements to ensure efficient marine litter including plastic waste and microplastics reduction and the prevention of its generation. To this aim the Contracting Parties shall endeavor to ensure:

    a) Institutional coordination, where necessary, among the relevant national policy bodies and relevant regional organizations and programmes, in order to promote integration;

    b) Close coordination and collaboration between national, regional and local authorities in the field of marine litter management;

12. By the year 2028, at the latest, the Contracting Parties shall take adequate regulatory measures to integrate the informal sector[10] into regulated waste collection and recycling schemes;

13. By the year 2025, the Contracting Parties shall establish, as appropriate, a regulatory framework for compostable plastics to be integrated into national waste management policies;

14. The Contracting Parties shall give due consideration to the implementation of the relevant related provisions of the Protocols[11] of the Barcelona Convention affecting marine litter management to enhance efficiency, synergies and maximize the results.

ARTICLE 9
Prevention of Marine Litter

15. In conformity with the objectives and principles of the Regional Plan the Contracting Parties shall:

---

[10] Informal recycling sector (IRS) refers to individuals or community enterprises who are involved in the recovery of material and waste management activities which are not necessarily sponsored, financed, recognized, supported, organized, or acknowledged by the formal solid waste authorities.

[11] Specifically in the framework of the Protocol Concerning Cooperation in Preventing Pollution from Ships and, in Cases of Emergency, Combating Pollution of the Mediterranean Sea, 2002 (Port reception facilities); Protocol for the Prevention and Elimination of Pollution of the Mediterranean Sea by Dumping from Ships and Aircraft or Incineration at Sea, 1995 (waste dumping prohibition); Protocol concerning Specially Protected Areas and Biological Diversity in the Mediterranean, 1995 (Regional Plans to protect endangered species; establishment of SPA and SPAMIs); Protocol for the Protection of the Mediterranean Sea against Pollution Resulting from Exploration and Exploitation of the Continental Shelf and the Seabed and its Subsoil, 1994 (prohibition of the disposal of garbage from offshore installations); and the Protocol on the Prevention of Pollution of the Mediterranean Sea by Transboundary Movement of Hazardous Wastes and their Disposal, 1996.

15.1 Apply to the extent possible instruments needed to regulate and prevent marine litter pollution including plastic waste from land-based and sea-based sources, in particular the implementation of **economic instruments**, bans and design requirements:

a) Extended Producer Responsibility;

b) Safe/formal markets for recycled plastics that incentivize the collection of plastic waste and, hence, reduce marine litter generation;

c) Fiscal and economic incentives or other equally effective measures (e.g. market restrictions) to promote the phasing out,-of light weight plastic carrier bags and other single-use plastic items which are most found and cause the most impact on the marine and coastal environment;

d) Innovative business practices to prevent plastic waste generation in line with the Extended Producer Responsibility approach by:

   i. Establishment of Deposit/Refund System for expandable polystyrene boxes in the commercial and recreational fishing and aquaculture sectors.

   ii. Establishment of Deposit/Refund System for food and beverage packaging, prioritizing when possible their reuse and recycling including deposit refund systems for bottles, containers and cans (e.g. glass, plastic and aluminium).

e) Best practices to create incentives for:

   i. Fishing vessels to retrieve derelict fishing gear, collect other items of marine litter, and deliver it to port reception facilities;

   ii. Delivering waste in port reception facilities such as the non-special fee system.

15.2 Apply by the year 2025, prevention measures aiming to achieve, to the extent possible, **a circular economy for plastics**:

a) Regulate the use of primary microplastics, as appropriate, by promoting voluntary commitments (e.g. certification schemes) or other actions (e.g. legal instruments);

b) Implement Sustainable Procurement Policies prioritizing the phase out of single-use plastic products and promoting reuse options. To this aim, the Contracting Parties may consider the list of Single Use Plastic items presented in Annex I to the regional Plan;

c) Establish voluntary agreements with retailers and supermarkets to set an objective of reduction of light weight plastic carrier bags consumption as well as selling dry food or cleaning products in bulk and refill special and reusable containers;

d) Establish procedures and manufacturing methodologies together with the plastic industry in order to minimize the decomposition characteristics of plastic and reduce microplastic;

e) Identify single-use plastic products which are most found and cause impacts on the marine environment and implement sound measures to phase out consumption and production and minimise the risk to end up in the marine environment. To this aim, the Contracting Parties may consider the list of Single Use Plastic items presented in Annex I to the Regional Plan;

f) Set targets to phase out production and use of nonreusable, non-recyclable, and non-compostable plastic products;

g) Take adequate measures to increase the reuse and recycling of plastics toward total plastic products;

h) Phase-out chemical additives used in plastic products, that may have serious and often irreversible effects on human health and the environment, and in particular those chemicals already listed under the Stockholm Convention contained as annex II of this Regional Plan;

i) Promote the use of recycled plastics and disincentivize the use of plastic, resins and additives which hinder products recyclability;

j) Endeavor to substitute plastics causing substantial impacts on the marine environment with materials with net positive impacts verified by life cycle assessment;

k) Implement standards for product labelling (including on packaging) to provide consumers with clear and reliable information on sustainable choices;

l) Establish dedicated collection and recycling schemes supported by Extended Producer Responsibility approach for end-of-life products;

m) Implement measures to minimize the amount of marine litter associated with fishing/aquaculture;

n) Scale-up and replicate sustainable models providing solutions to reduce single-use plastic products consumption;

15.3 Land-based Sources

a) By the year 2025, base urban solid waste management on reduction at source, applying the following waste hierarchy as a priority order in waste prevention and management legislation and policy: prevention, preparing for re-use, recycling, other recovery, e.g. energy recovery and environmentally sound disposal;

b) By the year 2019, implement adequate waste reducing/reusing/recycling measures in order to reduce the fraction of plastic packaging waste that goes to landfill or incineration without energy recovery;

c) Take the necessary measures by the year 2020 to close to the extent possible the existing illegal dump sites on land in the area of the application of this Regional Plan;

d) Take the necessary measures by 2027 to identify and, to the extent possible, restore and contain, the coastal landfills that are a source of marine litter;

e) Apply in accordance with national and regional legislation enforcement measures to combat dumping, littering on the beach, illegal sewage disposal from land sources in the sea, the coastal zone and rivers in the area of the application of this Regional Plan;

f) Taking into consideration the occurrence and extent of marine litter accumulations, identify and assess by the year 2025, impacts of these accumulations in upstream regions of rivers and their tributaries, and apply measures to prevent or reduce their leakage into the Mediterranean, particularly during flood seasons and other extreme weather events;

g) Apply enforcement measures to prevent, reduce and sanction illegal dumping and illegal littering in accordance with national and regional legislation, in particular on coastal zones and rivers in the area of the application of the Regional Plan;

15.4 Sea-based Sources

h) In accordance with Article 14 of the Prevention and Emergency Protocol, explore and implement by 2017, to the extent possible, ways and means to charge reasonable cost for the use of port reception facilities or when applicable, apply No-Special-Fee system. The Contracting Parties shall also take the necessary steps to provide ships using their ports with updated information relevant to the obligations arising from Annex V of MARPOL Convention and from their legislation applicable in the field;

i) Implement targeted measures by 2025 aiming at preventing and reducing marine litter impact in Marine Protected Areas (MPAs) and Specially Protected Areas of Mediterranean Importance (SPAMIs);

j) Explore and implement to the extent possible by the year 2017 "Gear marking to indicate ownership" concept and "reduced fishing catches through the use of environmental neutral upon degradation of nets, pots and traps concept," in consultation with the competent international and regional organizations in the fishing sector;

k) Apply by the year 2020 the cost-effective measures to prevent any marine littering from dredging activities taking into account the relevant guidelines adopted in the framework of Dumping Protocol of the Barcelona Convention;

l) Take the necessary measures to ensure that cruise ships flying their flag or entering their ports implement the procedures for minimizing, collecting, storing, processing and disposing of garbage;

m) Take the necessary measures to promote best practices to prevent plastic waste and particularly single use plastic products in tourism and leisure activities including cruise shipping, including through regional cooperation;

n) Implement measures on prevention, response and remediation regarding litter from maritime accidents, including containers lost at sea.

ARTICLE 10

Removing Existing Marine Litter and its Environmentally Sound Disposal

16 The Contracting Parties shall, where it is environmentally sound and cost effective, remove existing accumulated litter, subject to Environmental Impact Assessment procedure, in particular from Marine Protected Areas (MPAs) and Specially Protected Areas of Mediterranean Importance (SPAMI) and litter impacting endangered species listed in Annexes II and III of the SPA and Biodiversity Protocol. To this aim the Contracting Parties undertake to explore and implement to the extent possible the following measures by the year 2019. To this aim the Contracting Parties undertake to explore and implement to the extent possible the following measures by the year 2019:

a) Identify, in collaboration with relevant stakeholders, accumulations/hotspots of marine litter at sea and implement, as appropriate, national programmes on their regular removal and sound disposal;

b) Implement National Marine Litter Cleanup Campaigns on a regular basis and evaluate their effectiveness;

c) Implement Cleanup Campaigns on a regular basis driven by beach; concessionaries/ managers/ local authorities, including outside the touristic season;

d) Participate in International Coastal Cleanup Campaigns and Programmes;[12]

e) Apply as appropriate 'Adopt-a-Beach' or similar practices and enhance public participation role with regard to marine litter management;

f) Apply Fishing for Litter in an environmentally sound manner, based on agreed guidelines and best practice, in consultation with the competent international and regional organizations and in partnership with fishermen and ensure adequate collection, sorting, recycling and/or environmentally sound disposal of the fished litter;

g) Charge reasonable costs for the use of port reception facilities or, when applicable apply No-Special-Fee system, in consultation with competent international and regional organizations,

[12] e.g. International Coastal Clean-Up Day; the Ocean Day; etc.

when using port reception facilities for implementing the measures provided for in Article 10.

17 The Contracting Parties shall explore and implement to the extent possible by the year 2017 the "Fishing for Litter" environmentally sound practices to facilitate clean-up of the floating litter and the seabed from marine litter caught incidentally and/or generated by fishing vessels in their regular activities including derelict fishing gear. [To this aim, the Contracting Parties shall establish, to the extent possible [and as appropriate] by the year 2030, ALDFG removal and recycling programmes].

18 The Contracting Parties shall explore and implement to the extent possible by the year 2025, targeted activities for the localization and retrieval, and where possible, reuse or recycling of derelict fishing gear including through new environmentally sustainable technologies.

Part III – Assessment

ARTICLE 11
Assessment of Marine Litter in the Mediterranean

19 The Contracting Parties shall assess in the framework of ecosystem approach the state of marine litter, the impact of marine litter on the marine and coastal environment and human health, as well as the socio-economic aspects of marine litter management based on coordinated and, if possible, common agreed methodologies, national monitoring programmes and surveys.

20 The Secretariat shall prepare the assessment of marine litter in the Mediterranean every six years using results of the national monitoring programmes and applied measures with the view to address priority issues and major information and data gaps, using all other available relevant regional and international data and where appropriate responses by the Contracting Parties to specific marine litter related questionnaires prepared by the Secretariat.

21 The first Assessment of the state of marine litter in the Mediterranean based on the existing information shall be submitted to the meeting of the Contracting Parties two years after entry into force of the Regional Plan.

ARTICLE 12
Mediterranean Marine Litter Monitoring Programme

22 Based on ecosystem approach ecological objectives and integrated monitoring programme, and in synergy with the relevant international and regional guidelines and documents, the Contracting Parties, on the basis of the proposals of the Secretariat, shall:

a) Prepare the Regional Marine Litter Monitoring Programme, as part of the Integrated Monitoring and Assessment Programme (IMAP);

b) Establish in the year 2016 the Regional Data Base on Marine Litter which should be compatible with other regional or overarching databases;

c) Establish by the year 2014 Expert Group on Regional Marine Litter Monitoring Programme, in the framework of the implementation of the Ecosystem Approach.

23 For the purpose of this Regional Plan and in compliance with the monitoring obligations under Article 12 of the Barcelona Convention and Article 8 of the LBS Protocol, the Contracting Parties shall design by the year 2017 National Monitoring Programme on Marine Litter.

24 The National Monitoring Programmes should address:

a) The need for harmonization and consistency with the integrated regional monitoring programme based on ecosystem approach and consistency with other regional seas;

b) Aspects related to monitoring litter originating from riverine inputs;

c) The need for litter monitoring in high sensitivity areas (endangered species, key habitats, etc.), and in Specially Protected Areas in the Mediterranean (SPAMIs).

25 To this aim, the Secretariat shall prepare, in collaboration with the relevant regional organizations, by the year 2014 the Guidelines for the preparation of the National Marine Litter Monitoring Programmes.

Part IV – Support to Implementation

ARTICLE 13
Research Topics and Scientific Cooperation

26 The Contracting Parties agree to cooperate, with support from the Secretariat, with competent international and regional organizations and relevant scientific institutions, on marine litter issues that due to their complexity require further research.

ARTICLE 14
Specific Guidelines

27 The Secretariat in cooperation with relevant international and regional organizations, shall prepare specific guidelines, taking into account where appropriate existing guidelines, to support and facilitate the implementation of measures provided for in articles 9 and 10 of the Regional Plan. Subject to availability of external funds such guidelines shall be published in different Mediterranean region languages.

ARTICLE 15
Technical Assistance

28 For the purpose of facilitating the implementation of the measures and monitoring obligations as provided for in Articles 7 to 10 and 12 of the Regional Plan, technical assistance, transfer of knowhow and technology shall be provided, including capacity building, by the Secretariat to the Contracting Parties in need of assistance.

ARTICLE 16
Enhancement of Public Awareness and Education

29 Due to the nature of the marine litter management issue, enhancement of public awareness and education, and co-responsibility of all stakeholders are very important components of the marine litter management.

30 To this aim the Contracting Parties shall undertake to the extent possible, where appropriate, in synergy with existing initiatives in the field of education for sustainable development and environment, and in partnership with civil society, public awareness and education activities, with adequate duration and follow up, with regard to marine litter management including activities related to prevention and promotion of sustainable consumption and production.

ARTICLE 17

Major groups and Stakeholder Participation

31 For the effective implementation of the Regional Plan, the Contracting Parties shall encourage appropriate involvement of, and partnerships with, various stakeholders including local authorities, civil society, private sector (producers, garbage collection and treatment companies, etc.) and other stakeholders as appropriate:

a) Regional, National and local authorities;
b) Maritime sector;
c) Tourism sector;
d) Fisheries and Aquaculture;
e) Agriculture;
f) Industry; and
g) Civil society.

ARTICLE 18

Regional and International Cooperation

32 For the purpose of facilitating the implementation of the Regional Plan the Secretariat shall establish institutional cooperation with various relevant regional and global institutions and initiatives.

33 The Contracting Parties shall cooperate directly or with the assistance of the Secretariat or the competent international and regional organizations to address transboundary marine litter cases.

ARTICLE 19

Reporting

34 In conformity with Article 26 of the Barcelona Convention and Article 13, paragraph 2(d), of the LBS Protocol the Contracting Parties shall report on a biennial basis on the implementation of this Regional Plan, in particular the implementation of the above measures, their effectiveness and difficulties encountered and data resulting from monitoring programme as provided for in Article 12 of this Regional Plan.

35 The Contracting Parties shall review biennially the status of implementation of the Regional Plan upon its entry into force, on the basis of the regional report prepared by the Secretariat.

Part V – Final Provisions

ARTICLE 20

Implementation Timetable

36 The Contracting Parties shall implement this Regional Plan, in particular the above measures according to the timetables indicated in the respective Articles of the Regional Plan.

ARTICLE 21

Entry into Force

37 The present Regional Plan shall enter into force and become binding on the 180th day following the day of notification by the Secretariat in accordance with Article 15, paragraphs 3 and 4, of the LBS Protocol.

ARTICLE 22
Enforcement of Measures

38 The Contracting Parties shall take the necessary actions to enforce the measures in accordance with their national regulations.

ANNEX I: List of Single Use Plastic (SUP) Items

*Mediterranean priority list of SUPs per group of items**

Group of items	Items
Packaging	Bags
Smoking-related	Cigarette filters
Food and beverage packaging	Drink bottles, caps and lids
	Crisp packets and sweet wrappers
On-the-go food and beverage packaging	Cutlery, plates and trays
	Straws and stirrers
	Drinks cups and cup lids
	Food containers including fast food packaging
WC flushed items	Sanitary applications, including cotton buds, wet wipes and sanitary towels
Personal protective equipment	Masks and gloves

** Source of information: Regional Guidelines to tackle single use plastic products in the Mediterranean (UNEP/MAP SCP/RAC 2021)*

Annex II: List of Chemical Additives of Concern Used in Plastic Production

List of persistent organic pollutants (POPs) used as additives in plastics and listed in Annex A (elimination) and Annex B (restriction) to the Stockholm Convention as of 2021:[13]

Annex A:

- Decabromodiphenyl ether (commercial mixture, c-decaBDE).
- Hexabromobiphenyl.
- Hexabromocyclododecane (HBCDD).
- Hexabromodiphenyl ether and heptabromodiphenyl ether (commercial octabromodiphenyl ether).
- Tetrabromodiphenyl ether and pentabromodiphenyl ether (commercial pentabromodiphenyl ether).
- Short-chained chlorinated paraffins (SCCPs).
- Perfluorooctanoic acid (PFOA), its salts and PFOA-related compounds.
- Polychlorinated biphenyls (PCB).
- Polychlorinated naphthalenes.

Annex B:

- Perfluorooctane sulfonic acid (PFOS), its salts and perfluorooctane sulfonyl fluoride (PFOSF)

List of additives used in plastics and identified as substance of concern in the information document of the 2019 Meetings of the conferences of the Parties to the Basel, Rotterdam and Stockholm conventions (UNEP/POPS/COP.9/INF/28/Add.1 - Plastic and toxic additives, and the circular economy: the role of the Basel and Stockholm Conventions) and main sectors concerned:

1. Substances of concern:

- **Flame-retardants**: polybrominated diphenyl ethers (PBDEs) including commercial pentabromodiphenyl ether (tetraBDE and pentaBDE), commercial octabromodiphenyl ether (hexaBDE and heptaBDE), decabromodiphenyl ether (decaBDE); decabromodiphenylethane (DBDPE); tetrabromobisphenol A (TBBPA); phosphorous flame retardants (e.g. tris(2-chloroethyl)phosphate (TCEP) and tris(2-chlorisopropyl) phosphate (TCPP); short-, medium- and long- chain chlorinated paraffins (SCCPs, MCCPs, LCCPs); boric acid; hexabromocyclododecane (HBCDD); Dechloranes in all its forms (e.g. Dechlorane 602, Dechlorane 603, Dechlorane 604 and Dechlorane Plus); hexabromobiphenyl (HBB); 1,2-bis (2,4,6- tribromophenoxy) ethane (BTBPE); hexabromobenzene (HBBz).
- **Perfluorinated chemicals**: perfluorooctane sulfonic acid (PFOS), its salts and perfluorooctane sulfonyl fluoride (PFOSF), perfluorohexane sulfonic acid (PFHxS), its salts and PFHxS-related compounds, perfluorooctanoic acid (PFOA), its salts and PFOA-related compounds.
- **Phthalates:** phthalic acid esters (phthalates); di(2-ethylexyl) phthalate (DEHP); diisononyl phthalate (DiNP); diisodecyl phthalate (DiDP); di(2-Propyl Heptyl) phthalate (DPHP).
- **Bisphenols**: bisphenol A; 4-tertiary-octylphenol; bisphenol B; bisphenol F; and bisphenol S.
- **Nonylphenols**: nonylphenols (NP); nonylphenol ethoxylates (NPE).

[13] As of 2021 - New additives are under revision by the POPs Review Committee, for inclusion under the Stockholm Convention: Dechlorane Plus (flame retardant) and UV-328 (antioxidant). Likewise, the POPs Review Committee recommended to list PFHxS, it's salts and PFHxS-related compounds under Annex A to the Stockholm Convention (Elimination).

2. Polymers and their additives are extensively used in the following categories of consumer products:

- Children's products.
- Packaging: food and beverage contact materials.
- Electrical and electronic equipment (EEE) and related waste (WEEE/E-waste).
- Textile, upholstery and furniture.
- Construction sector.

Appendix 6

Updated Baseline Values and Proposal for Threshold Values for IMAP Common Indicator 22

1. Objective

1. The objective of the present document is to elaborate/formulate/update marine litter assessment criteria at regional and sub-regional levels, taking into account recent developments on the national and regional levels concerning marine litter monitoring and assessment, and most importantly the outcomes of implementation of the Integrated Monitoring and Assessment Program of the Mediterranean Sea and Coast and Related Assessment Criteria (IMAP). This document includes a proposal for updated the Baseline Values (BV) for IMAP Common Indicator 22 (CI22) (beach macro-litter), to replace those agreed in 2016 (Decision IG.22/10 – Annex III), as well as to establish Threshold Values (TV) for IMAP CI22 underpinning comparable and compatibly assessment criteria at regional and sub-regional levels.

2. Conceptual Approach, Definition and Estimation of Marine Litter Baseline and Threshold Values

2.1 Baseline Values

2. After the adoption of the Regional Plan on Marine Litter Management in the Mediterranean in 2013 (Decision IG.21/7), UNEP/MAP adopted in 2016 the Marine Litter Baseline Values (Decision IG.22/10 – Annex II) against which the implementation of the Regional Plan programs of measures could be assessed. These baseline value would enable the establishment of Marine Litter Environment Reduction Targets (Decision IG.22/10), as well as assessing whether Good Environmental Status (GES) is met. They also provide guidance on the way forward for the effective marine litter management in the region.

3. Definition of Baseline Values: According to definition provided by the UNEP/MAP Informal Online Group on Marine in 2015[14], "*A baseline is a description of environmental state at a specific point against which subsequent values of state are compared. It may refer to a specified level of an impact or a pressure and act as a reference against which limit can be set or trends for the assessment of GES. Baselines can be derived from reference conditions, initial assessment values, the present state or a potential/predicted issue."*

4. The Joint Research Centre (JRC) of the European Commission (EC), introduced a similar definition: "*A baseline value for marine litter refers to the information related to marine litter abundance that can be used as reference point in time in order to test the achievement of quantitative litter reduction goals (JRC, 2019).*"

5. In the framework of the Ecosystem Approach (EcAp), UNEP/MAP adopted in 2016 a series of Baseline Values for marine litter based on a thorough analysis of existing marine litter data and information, taking into consideration the IMAP marine litter-related indicators 22, 23 and 24. This analysis was conducted by the UNEP/MAP Informal Online Group on Marine Litter in 2014-2015 and was considered and approved by the Meeting of the Integrated Monitoring Correspondence Group in 2015 (Athens, Greece, 30 March – 1 April 2015).

6. Baseline values will and can be used at different organizational levels for evaluating the compliance with reduction goals, and thus their setting is crucial in the entire process for reducing marine litter.

2.2 Threshold Values

[14] UNEP/MED WG.411/Inf.10: First Report of the Informal Online Group on Marine Litter. Meeting of the Integrated Monitoring and Assessment Group (Athens, Greece, 30 March – 1 April 2015).

7. Definition of Threshold Values: The New GES Decision (2017/848) of the European Commission (EC) provides a definition for the Threshold Values for marine litter: "*Threshold value means a value or range of values that allows for an assessment of the quality level achieved for a particular criterion, thereby contributing to the assessment of the extent to which good environmental status is being achieved.* "

8. For the determination of Threshold Values (TV), pristine or next to pristine areas/ environments should be considered. Due to the ubiquity of plastic in the marine environment worldwide, it is very difficult to define/find a pristine area, which for some experts does not even exists (Matiddi M. et Al., 2019).

9. The European Union (EU) Marine Strategy Framework Directive (MSFD) Technical Group on Marine Litter (TGML) proposes a threshold value, not based on evidence of ecological harm, which cannot be assessed in practice. Rather, it considers that there is some degree of freedom to establish a threshold value and an assessment method which shows a good level of ambition, is feasible (e.g. by selecting a low percentile value; percentile 1 and percentile 5), practical, and robust to apply (e.g. using the low percentile threshold value and the median assessment value). In that respect, a lower threshold value results in a lower residual risk of ecological harm (Willem van Loon et al. 2019).

10. For the determination of the baseline and threshold values in the Mediterranean, UNEP/MAP has embarked on the IMAP implementation, establishing and implementing national monitoring programmes for marine litter across the Mediterranean. Relevant data sets deriving from national monitoring programmes will be gradually available during the 2020-2021 biennium. These programmes are expected to support the process for achieving GES with quality controlled and quality assured data.

3. Data Sets and Data Management

11. Marine litter Baseline and Threshold Values are strongly linked and associated with data availability and data quality. Data should be acquired through harmonized monitoring methodologies in order to provide comparable data. This continues to be a challenge, though much progress has been made in the framework of IMAP, whereby data are streamlined through the development of relevant information standards (i.e. Data Standards (DS) and Data Dictionaries (DD)) for the pollution and marine litter indicators, as well as the finalization of the IMAP InfoSystem.

12. Quantitative data necessary to assess abundance, trends and distribution of marine litter are required in order to put in place and implement targeted and effective prevention and reduction measures for marine litter in the Mediterranean. While monitoring of marine litter has been ongoing for several years, it is not yet possible to get a comprehensive overview and thus to analyze the abundance of marine litter; distribution; categories; and trends in different spatial scales from local areas throughout the Mediterranean Sea. In that regard, there is still a need to further harmonize data collection methods, protocols and their analysis at all levels (e.g. categories, units, etc.).

13. The following information and data are required in order to establish marine litter baseline values:

- Ideally, data collected using the same, or a comparable, monitoring protocol;
- Data with sufficient spatial coverage;
- Data with sufficient temporal coverage;
- Data with sufficient "fit-for-purpose" quality;
- Agreement on a procedure for data clean-up; and
- Agreement on a baseline calculation method.

14. Moreover, it is crucial to agree on several variables related to data management and treatment (JRC, 2019), which include the following:

- The time period from which data is used for the calculation of baselines;
- The temporal aggregation of data;
- The spatial aggregation of data; and
- The mathematical procedure used for baseline calculation.

15. Guidance elements, to further strengthen data submission via corresponding data flows, as well as how these can be used for the determination of baseline and threshold values for marine litter are provided under Annex I to the present document.

4. Methodological Approach to determine Baseline and Threshold Values on Marine Litter at Regional and Sub-Regional Levels in the Mediterranean

16. For the definition of baseline and threshold values for each common IMAP marine litter indicator (i.e. beaches, sea bottom and water column), the data used correspond to data collected from Contracting Parties to the Barcelona Convention between 2016 and 2018 deriving from monitoring programmes, projects and initiatives, after taking into consideration the comparability of the submitted data sets. The selection of the 2016-2018 period is due to the availability of full years data in a significant number of countries compared to previous years in which data availability was rather limited.

17. Considering all available information from Contracting Parties, all steps have been undertaken in close collaboration with, scientific community and other sources from the literature. The discussion and set-up of baseline values has also taken into consideration the ongoing discussions on marine litter monitoring, top-litter item identification and establishment of threshold values (i.e. JRC, 2019).

4.1 IMAP Candidate Indicator 22: Beach Marine Litter

18. For IMAP Common Indicator 22 (beach marine litter), thirteen (13) Countries have contributed with data for the present exercise. The set of data resulting from different surveys and initiatives were based on protocols with several differences. Therefore, the datasets were homogenized towards ensuring comparability, before performing the statistical analysis. Under the present exercise, it is presumed that data provided by the respective Focal Points have undergone thorough quality checks and do not contain erroneous data.

19. All the surveys have been collected in a database in accordance with the templates proposed by UNEP/MAP in accordance with monitoring programs on marine litter in the Mediterranean (UNEP/MAP, 2017). The extreme values that have been observed (outliers) were retained in the datasets and were checked and verified case by case. The number of surveys conducted in each country and the year when it was undertaken for beach marine litter (IMAP CI22) are presented in Table 1.

Table 1: Number of surveys by country (beach litter)

Sub-regions[15]	Country	Surveys	Years	Sources
WM	Algeria	111	2018	SWIM H2020 Support Mechanism
	France	88	2016, 2017, 2018	MED POL Focal Point France
	Italy	162	2016, 2017, 2018	MEDPOL Focal Point Italy

[15] Western Mediterranean (WM); Central Mediterranean (CM); Adriatic Sea (AS); Eastern Mediterranean (EM)

Sub-regions[15]	Country	Surveys	Years	Sources
	Malta	24	2017, 2018	MED POL Focal point Malta
	Morocco	16	2018	MED POL Focal point Morocco
	Spain	139	2016, 2017, 2018	MED POL Focal Point Spain
CM	Greece	3	2018	MED POL Focal Point Greece
	Italy	66	2016, 2017, 2018	MED POL Focal Point Italy
	Libya	12	2018	MED POL Adopt-a-Beach Pilots in Libya
AD	Italy	132	2016, 2017, 2018	MED POL Focal Point Italy
	Slovenia	16	2017	MED POL Focal Point Slovenia
	Montenegro	4	2018	MED POL Adopt-a-Beach Pilots in Montenegro
	Albania	4	2018	MED POL Adopt-a-Beach Pilots in Albania
	Croatia	6	2017, 2018	MED POL Focal Point Croatia
EM	Cyprus	31	2016, 2018	EMODnet
	Israel	8	2017, 2018	MED POL Focal Point Israel

5. Determination of Baseline and Threshold Values

5.1 IMAP Candidate Indicator 22: Beach Marine Litter

20. For each country and subregion, the basic statistical values have been calculated together with average and median values corresponding to the total amounts of marine litter found in each survey by year and then by country as illustrated in Table 4. The beach litter data distribution is shown in Fig. 1.

Table 4: Descriptive statistics parameters by country

Country	Average	Standard Deviation	Median
Albania	757	375	681
Algeria	782	587	625
Croatia	936	928	768
Cyprus	339	409	218
France	893	1513	436
Greece	1502	1501	708
Israel	157	154	128
Italy	762	872	475
Libya	2206	1185	2002
Malta	204	237	127
Montenegro	1440	1372	968
Morocco	1744	1398	1327
Slovenia	374	273	328
Spain	306	367	167
Total average	**924**	**832**	**659**

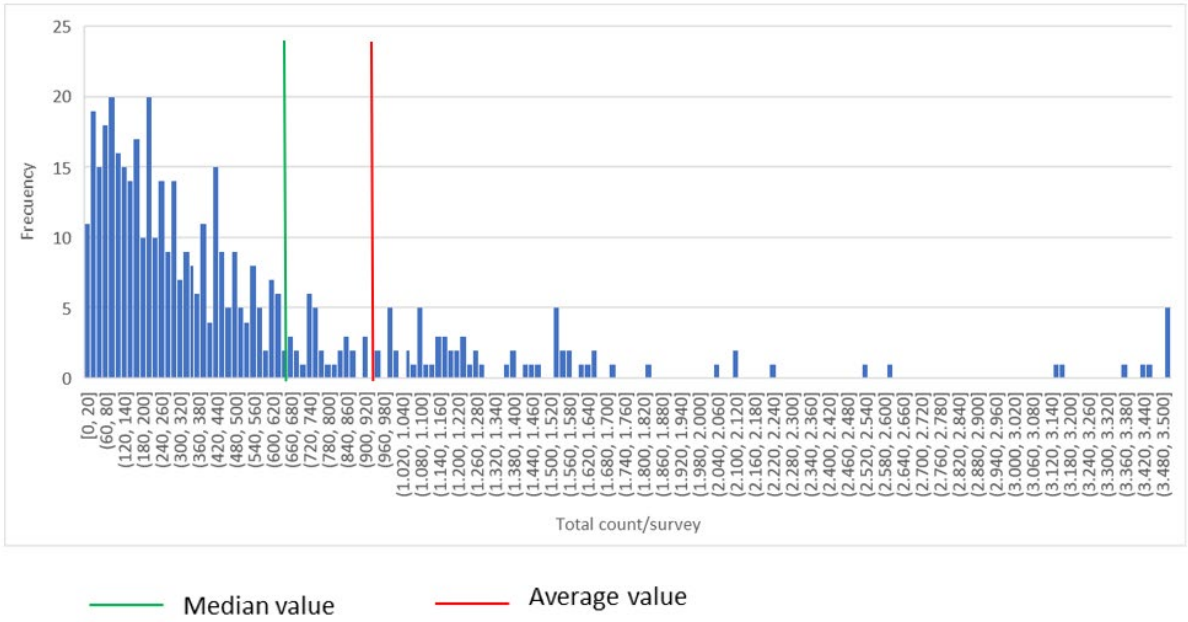

Figure 1: Beach litter data distribution

21. As can be seen, non-symmetrical distributions are predominant in the marine litter count (Table 4 and Figure 1). Further examination of data presented in both Figure 5 and Table 2 indicate that the standard deviation is very high, even greater than the average for some countries, and at the level of the Mediterranean, it gives a very wide range of average values (i.e. Spain: average 306 items/100 m; standard deviation 367 items/100 m, Table 4). The graphic representation under Figure 1 shows that the data distribution for IMAP CI22 (beach marine litter) is very irregular; and thus, **the median value is the most representative**. In fact, the median value is considered a better measure of the central location of a value than the average value in the case of a non-symmetric distribution (Baggelaar, Paul K. and Van der Meulen Eit C.J., 2014; Willem van Loon et al., 2019). This is due to the reason that, the median value is not sensitive to extreme values (Willem van Loon et al. 2019). For example, the median beach litter abundance values of France (Table 4) are much more comparable with other countries' median abundance values than the average values. Extreme values may sometimes occur, e.g. due to a storm event or an accidental loss of litter at sea. For all countries, the use of the median value will make the assessment insensitive to these occasional extreme values (Willem van Loon et al. 2019).

22. The best spatial coverage is considered to be the combination of "Country" and "Sub-region" (i.e. Country-SubRegion) (JRC, 2019). The Top-X calculation was conducted for each consecutive year for the period 2016-2018 (i.e. 2016, 2017 and 2018), and for each Country-SubRegion (e.g. IT-AD, IT-CM, IT-WM, etc.).

23. The Mediterranean Top-X marine litter items list that contributed to the 80th percentile of the total recorded items for the period 2016-2018 for each Country-SubRegion are presented in Table 5 (Baggelaar, Paul K. and Van der Meulen Eit C.J., 2015). The Top-X and Top-10 marine litter lists per country can be found under Annex II to this document.

Table 5: Relative and cumulative frequency of marine litter in the Mediterranean (Top 10 and Top X)[16]

		UNEP Code	Item name	Relative Frequency.[17]	Cumulative Frequency
Mediterranean Top-10 Marine Litter Items	Mediterranean Top-X (80%) Marine Litter Items	G76	Plastic/polystyrene pieces 2.5 cm > < 50 cm	0,16504423	0,16504423
		G27	Cigarette butts and filters	0,12921627	0,2942605
		G21/G24	Plastic caps and lids (including rings from bottle caps/lids)	0,08743357	0,38169407
		G95	Cotton bud sticks	0,05249481	0,43418888
		G7/G8	Drink bottles	0,04973091	0,48391979
		G30/G31	Crisps packets/sweets wrappers/Lolly sticks	0,03998183	0,52390162
		G124	Other plastic/polystyrene items (identifiable) including fragments	0,03299665	0,55689827
		G50	String and cord (diameter less than 1 cm)	0,02712216	0,58402043
		G208a	Glass fragments >2.5cm	0,02302928	0,60704971
		G200	Bottles (including identifiable fragments)	0,02032637	0,62737608
		G73	Foam sponge items (i.e. matrices, sponge, etc.)	0,01956879	0,64694487
		G34/G35	Cutlery, plates and trays / Straws and stirrers	0,01892997	0,66587484
		G3	Shopping bags incl. pieces	0,0179509	0,68382574
		G10	Food containers incl. fast food containers	0,01342144	0,69724718
		G33	Cups and cup lids	0,01306833	0,71031551
		G204	Construction material (brick, cement, pipes)	0,01288535	0,72320086
		G152	Cigarette packets	0,01184849	0,73504935
		G67	Sheets, industrial packaging, plastic sheeting excluding agriculture and greenhouse sheeting	0,01109412	0,74614347
		G4	Small plastic bags, e.g. freezer bags incl. pieces	0,01085015	0,75699362
		G175	Cans (beverage)	0,01072495	0,76771857
		G54	Nets and pieces of net > 50 cm	0,01030122	0,77801979
		G158	Other paper items (including non-recognizable fragments)	0,01023381	0,7882536
		G145	Other textiles (including pieces of cloths, rags, etc.)	0,01013108	0,79838468

24. The Mediterranean Top-X list includes 23 items (from G76 to G145) and represents approximately 80% of the information collected, while the Top-10 list only represents 63% of the information (Table 5).

25. The parameter used in the analysis (median) was defined and a weighing factor was applied. The weighing factor has been calculated as the percentage of the length of the coast corresponding to each country within its subregion and within the entire Mediterranean coast (JRC, 2019) (Table 6).

26. Accordingly, it was found that the data provided by the Contracting Parties represent 60% of the total length of the Mediterranean coastline. The analysis must take into account a weighting factor

[16] The Relative and cumulative frequency for the full UNEP/MAP list for beach marine litter items is presented under Annex III.
[17] Objects with relative frequencies <0.01 are excluded from the Top X (Baggelaar, Paul K. and Van der Meulen Eit C.J., 2015).

based on the length of coast of each country in each subregion, and of each subregion in the total Mediterranean coast to increase spatial representativeness. This approach significantly increased the data representativeness as illustrated in Table 6.

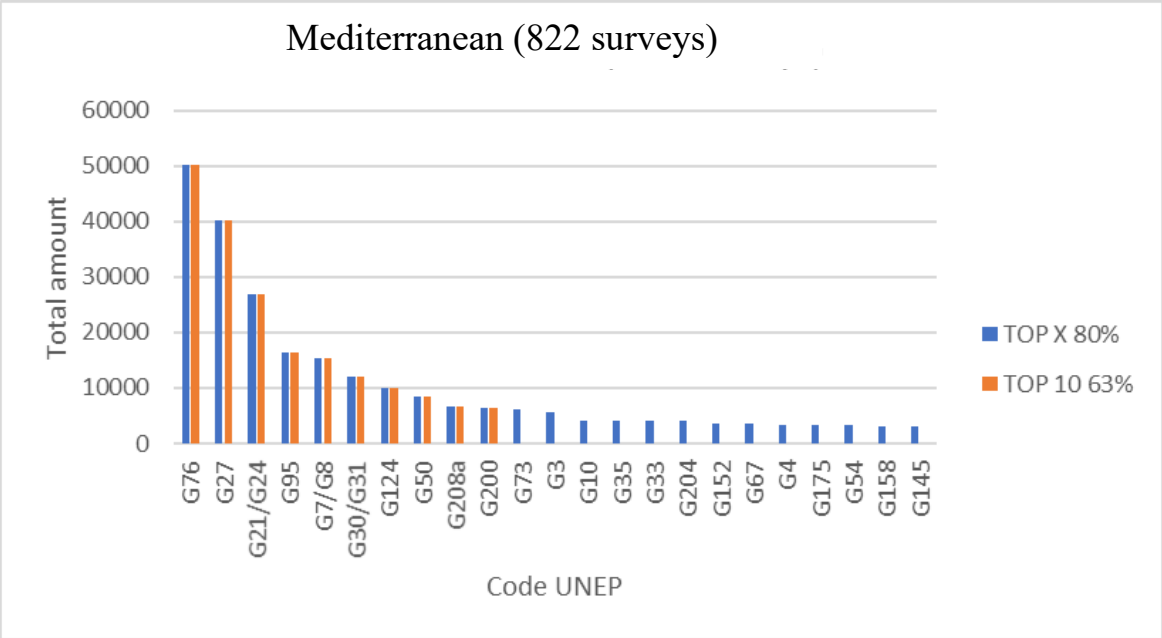

Figure 2: Top-X vs. TOP-10 marine litter items per Mediterranean (Table 6)

Table 6: Percentage of the Mediterranean coast by country (World Resources Institute, 2016)

		TR	47

27. This methodology was applied to 100% of the data obtained to determine the baseline that will be compared to the values previously proposed (UNEP/MAP, 2016). Further to the above analysis, the baseline values for beach marine litter were calculated as depicted in Table 7:

Table 7: Median by sub-region and Mediterranean

	Median (item/100m)
Mediterranean Sub-regions	**100% data set**
WM	384
CM	338
AD	547
EM	205
Mediterranean Sea AVERAGE	**369**

28. Hence**,** for **IMAP Common Indicator 22 (beach marine litter), the proposed, updated Baseline Value for the Mediterranean is 369 item/100 m** (Table 8). The beach litter baseline proposed by 19th Ordinary Meeting of the Contracting Parties to the Convention for the Protection of the Marine Environment and the Coastal Region of the Mediterranean and its Protocols (Athens, Greece, 9-12 February 2016) was 450-1400 items/100 m.

29. To calculate the threshold value, it was proceeded with the estimation of the 15th percentile of the baseline results (Willem van Loon, David Fleet and Georg Hanke, 2019). Against which to compare the state of beach marine litter in the Mediterranean, following the marine litter descriptor aim.

30. In order to give each sub-region an equal contribution, it is proposed to give each an equal weight while calculating the corresponding threshold value/s in accordance with the 15th percentile as shown in Table 8. This method will prevent data of one or more countries with many surveys or with extremely high or low total abundance values from dominating the threshold value (Van Loon et al, 2019).

31. As can be inferred from Table 8 (Q15), for **IMAP Common Indicator 22 (beach marine litter), the proposed Threshold Value is 130[18] items/100 m**.

Table 8: Percentile calculation

Sub regions	**Q15 (items/100m)**
	100% data set
WM	87
CM	135
AD	225
EM	73

[18] The proposal of a Threshold Value is a strategic decision. The value 177 items/100m corresponds to the average value for the Mediterranean.

Total average	**130**

32. In order to reach achieve GES, a reduction percentage should be applied in order to give overall information about the reduction level that should be applied on the baseline value in order to comply with the proposed/calculated Threshold Value. The reduction percentage is calculated as per Van Loon et al. (2019) as follows:

$$\text{Reduction Percentage} = ((\text{median} - \text{TV}) / \text{median}) \times 100$$

33. Accordingly, it is found that the reduction percentage between the proposed Baseline Values and the proposed Threshold Value for the Mediterranean is approximately 65%

6 Proposal for Updated Baseline Values and Establishment of Threshold Values for Marine Litter

34. Based on the datasets that were made available to UNEP/MAP and its MED POL Programme and the relevant analysis elaborated to the present document a proposal for updated Baseline Values and Threshold Values, at this stage can be considered only for IMAP Common Indicator 22 (beach macro-litter). Those proposals are presented hereunder under Table 12.

Table 11: 2016 (Agreed) and 2019 (Proposed/Updated) Baseline Values; Proposed Threshold Values; and percentage reduction in baseline values to achieve GES.

IMAP Indicators	Categories of Marine Litter	BV-2016	Proposed BV-2021	Proposed TV-2021
CI22	Beach Marine Litter	450-1400 items/100m	**369 items/100m**	**130 items/100m**

Annex II: Guidance elements, to further strengthen data submission and corresponding data flow for marine litter, for the determination of baseline and threshold values

1 Field guides and litter identification tools are important elements which ensure sampling consistency throughout the region. Guides should be developed in local languages and address cultural aspects.

2 Under UNEP/MAP IMAP framework, the most comprehensive document for data collection is provided through the "Integrated Monitoring and Assessment Guidance" (UNEP, 2016) where the sampling and data collection methodologies are detailed for different environments under study. The aforementioned document addresses the following survey categories:

A. Beach litter surveys.
B. Benthic litter surveys, which include:
    a. Observations made by divers, submersibles or camera tows.
    b. Collection of litter via benthic trawls.
C. Floating litter surveys, which include:
    a. Observations made from ship or aerial based platforms.
    b. Collection of litter via surface trawls.

3 During the 2019 Meetings of the MED POL Focal Points (Istanbul, Turkey, 29-31 May 2019), and 7th EcAp Coordination Group (Athens, Greece, 9 September 2019), Data Standards (DS) and Data Dictionaries (DD) for marine litter IMAP Common Indicators were agreed based on the work of CorMon on Marine Litter (Podgorica, Montenegro, 4-5 April 2019), including a detailed list of parameters and relevant elements that should be recorded during the monitoring surveys. Based on these parameters, single forms in excel format were recommended for reporting of marine litter data in different environments (e.g. beach, seafloor, floating, etc.). The forms are to include relevant information for subsequent data analysis (e.g. country, sub-region, location, survey date, etc.). The following steps are recommended for the submission and analysis of relevant data for marine litter items in a coherent and coordinated manner:

4 Step 1: Development of Datasets

5 Contracting Parties' Focal Points should send a file in excel format annually with data corresponding to each survey category.

6 The file name should have the following labeling:

Sub-regionCode_CountryCode_Year (yyyy)

7 Step 2: Statistical analysis (beach macrolitter, seafloor macrolitter and floating macrolitter)

8 The collected marine litter data and relevant excel sheets are subsequently developed in R-Language19 with which data files are read and analyzed. Accordingly, a final report is generated.

9 For the exercise elaborated under the present document, the 2016-2018 datasets were consolidated in R-Language in ".csv" format under schematic representation shown in Figure 1:

[19] Statistical programme

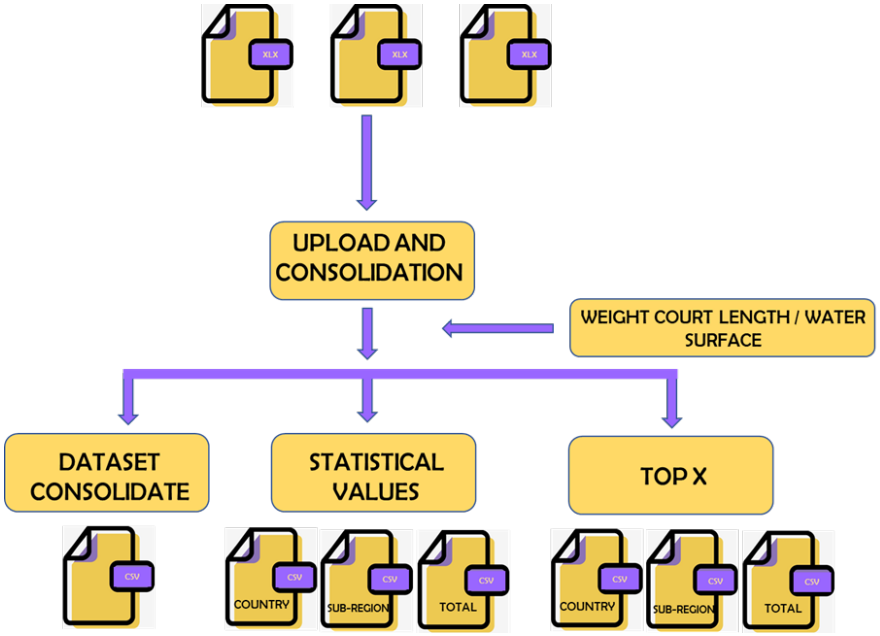

Figure 1: Schematic representation of the methodological approach for the collection of the available datasets and the statistical treatment of the data.

10 Step 3: Calculation of Baseline and Threshold Values

A. Baseline Values: The schematic representation of the methodological approach for the calculation of baseline values based on median approach are depicted in Figure 2.

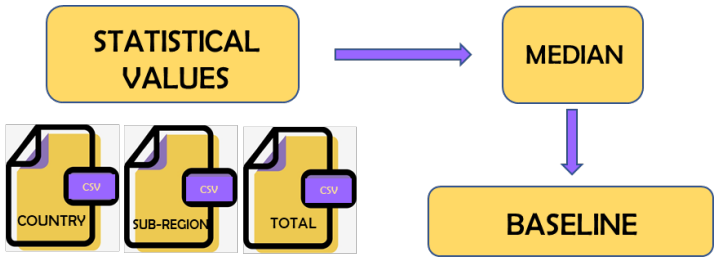

Figure 2: Schematic representation of the methodological approach for the calculation of baseline values.

B. Threshold Values: There is some freedom to establish a threshold value and an assessment method which shows a good level of ambition and is considered feasible and realistic. Here we show one possibility based on the 15Q) (Figure 3).

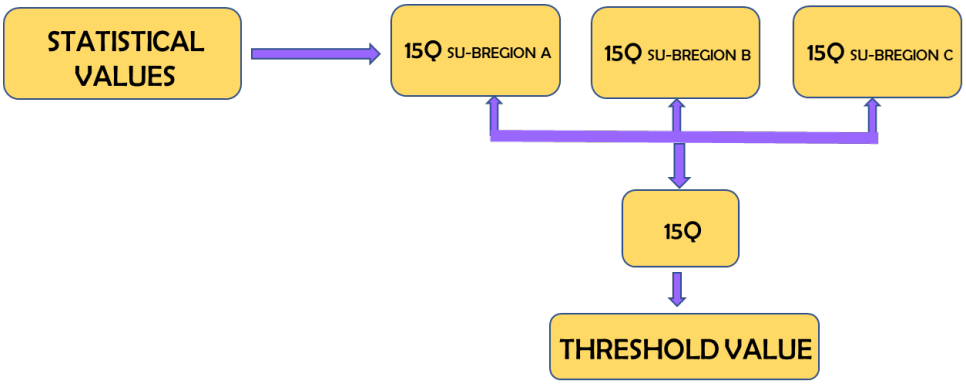

Figure 3: Schematic representation of the methodological approach for the calculation of threshold values.

Appendix 7

Background (Assessment) Concentrations (BC/BAC) for Common Indicator 17 and Upgraded Approach for Environmental Assessment Criteria (EAC) for IMAP Common Indicators 17, 18 and 20

1 Introduction

1. The criteria established by Decisions IG.22/7 (COP 19)[20] and IG. 23/6 (COP 20)[21] are reviewed in Section 2 of present document, whereas Section 3 provides an in-depth analysis of the data available for present upgrade of the assessment criteria. New upgraded regional and sub-regional Mediterranean BC and BAC values for CI17, as well as a proposal of the criteria for IMAP CI20 are presented in Section 4. This section also proposes an approach to upgrade the Mediterranean EACs.

2. The data used for developing updated assessment criteria were collected in the IMAP Pilot Info System during its testing phase, and in particular after launching a formal call for reporting of monitoring data in June 2020, as well as monitoring data stored in MEDPOL database that have not been previously used for calculation of the assessment criteria applied in the 2017 and 2019 assessments. It also took into account data from EU data center (European Marine Observation and Data Network - EMODnet), as a reliable external data source, as well as data collected from the scientific literature. A detailed compilation of the available new data is given in Section 3.

2 The assessment criteria for IMAP Common Indicators 17 and 18

3. Deriving and setting up criteria to determine environmental status is not an easy task. It gets more complicated going from the local to sub-regional and regional assessments. While there are many methodologies to derive criteria, the first step is aimed at defining the background or reference conditions from which to measure/determine the status and trends. In the framework of UNEP/MAP (UNEP/MAP 2016, 2019), the background concentration (BC) is defined as "The concentration of a contaminant at a "pristine" or "remote" site based on contemporary or historical data". The BC of anthropogenic (man-made) substance was defined as zero.-The same definitions are used by OSPAR and the Marine Strategy Framework Directive (MSFD) based on the Water Framework Directive (WFD) (Tornero et al. 2019)[22].

4. In line with these definitions, the BC determination is the first step of the derivation of indicators that are defined as the measure, index or model used to estimate the current state and future trends, along with thresholds for possible management action.

2.1 Methodology for background concentration (BC) determination

5. Several methods can be used to derive BC values for natural occurring elements/substances in different environmental matrices (i.e. sediment and biota)[23]. Briefly, they include using global average concentrations; pre-industrial age data; current data from pristine sites; data from monitoring programmes, whereas known polluted sites are excluded.

2.2 The methodology for the determination of Background concentration (BC) used by UNEP/MAP

6. The BCs were derived using data from sediment cores compiled from the scientific literature (UNEP/MAP 2011) and data from the MEDPOL database (UNEP/MAP 2011, 2016, 2019). A complete explanation of the used methodologies is given in these documents, as well as in UNEP/MAP WG.492/Inf.11 submitted for consideration of present Meeting.

2.2.1 Trace Metals (Cd, Hg and Pb) in sediments

7. The approved BCs for Trace Metals (TM) in sediments are summarized in Table 1. Briefly, in 2016, the first step was to choose the stations to be considered as reference at a country level. For each country, each parameter was grouped by year and the years without temporal trend chosen. Next, the parameters were grouped by stations and the overall median value computed. Stations where the 75th percentile of the data were below the overall median were chosen as reference stations. Data of the

[20] UNEP/MAP (2015). Decision IG.22/7 on Integrated Monitoring and Assessment Programme of the Mediterranean Sea and Coast and Related Assessment Criteria (Annex II), (COP 19, 2015).
[21] UNEP/MAP (2017). Decision IG.23/6 on Mediterranean Quality Status Report (COP20, 2017).
[22] Additional definitions for BC can be found in the literature and are explained in UNEP/MAP WG.492/Inf 11 submitted for information to present meeting.
[23] See document UNEP/MAP WG.492/Inf 11.

reference stations were aggregated for the whole Mediterranean Sea and the MedBC computed as the median value of all reference stations. In 2019, BC values were computed in a similar way for 3 out of the 4 Mediterranean sub-regions[24]: Western Mediterranean (WMS), Adriatic Sea (ADR) and Aegean-Levantine Seas (AEL)[25]. No data were available to calculate BC for the Central Mediterranean (CEN). It was recommended to normalize the concentrations to Al (5%) concentrations[26].

Table 1. Background concentrations (BC) and Background assessment concentrations (BAC) calculated for trace metals (TM) in sediments for the Mediterranean Sea and sub-regions in 2011 and 2019. The table also presents the MedBAC and MedEAC values agreed upon in Decisions IG.22/7 and IG.23/6. Concentrations are given in µg/kg dry wt, as requested by IMAP[27].

	Decisions IG.22/7 and IG.23/6 (COP 19 and COP 20)			**UNEP/MAP (2011)**		**UNEP/MAP (2019)**			
	MedBAC	MedBAC	MedEAC*	Med BC	Med BC	Med BC	BC	BC	BC
TM	IG.22/7	IG.23/6	IG.23/6	Sed cores	Surf Sed	Ref Stn	WMS	ADR	AEL

Pb	30000	25425	46700	20000	2310	16950	20465	13932	4920

* ERL (Effects Range Low, Long et al. 1995, idem OSPAR values). Sediment (Sed); Surficial (Surf); Reference stations (Ref Stn); Western Mediterranean (WMS); Adriatic (ADR) Aegean; Levantine Sea (AEL). No data were available to set up BCs for the Central Mediterranean (CEN).

8. Further to this work, present document (Section 4) provides updated BC and BAC values for TM in sediments. They were calculated by using the new data and the same methodologies as applied in 2016 and 2019

2.2.2 Naturally occurring organic compounds (PAHs) in sediment

9. MedBC values for PAHs in sediments are summarized in Table 2. The BCs were computed based on data derived from sediment cores compiled from the scientific literature, as well as data available in MEDPOL database (UNEP/MAP 2011). Normalization of organic compounds concentrations to total organic carbon (TOC) (2.5%) was recommended.

Table 2. Background concentrations (BC) calculated for PAHs in sediments for the Mediterranean Sea in 2011. The table also presents the MedEAC values agreed upon in Decisions IG.22/7 and IG.23/6. Concentrations are given in µg/kg dry wt, as requested by IMAP.

	Decisions (COP 19 and COP 20)	**UNEP/MAP (2011)**	
PAH compounds	**EAC* IG.22/7 and IG.23/6**	**BC Sed cores**	**BC Sur sed**
Naphthalene (N)		4	
Acenaphthylene (ACY)		0.5	1.05
Acenaphtene (ACE)		0.38	0.45
Fluorene (F)		0.75	0.33
Phenanthrene (P)	240	4.55	3.95

[24]Although sub-regional values for the BCs in sediment were proposed, an updated 2019 assessment used the ones calculated in 2016, awaiting further confirmation of sub-regional values when new reference datasets will be available, whilst for mussels the proposed sub-regional values of BCs were exercised.
[25] The Mediterranean sub-regions and subareas are initially proposed according to availability of database sources for calculation of the assessment criteria (UNEP(DEPI)/MED WG.427/Inf.3; UNEP/MED WG.463/8; UNEP/MED WG.467/7).
[26]Normalization should be used with care, and only if field data support that normalization is valid for the area. An explanation on normalization practice for monitoring of IMAP Common Indicator 17 is provided in Monitoring (Guidelines/Protocols for Sample Preparation and Analysis for sediments (UNEP/MAP WG.482/12) and biota (UNEP/MAP WG.482/14)).
[27]UNEP/MED WG.467/5. IMAP Guidance Factsheets: Update for Common Indicators 13, 14, 17, 18, 20 and 21: New proposal for candidate indicators 26 and 27; UNEP/MED WG.467/8. Data Standards and Data Dictionaries for Common Indicators related to Pollution and Marine Litter.

PAH compounds	Decisions (COP 19 and COP 20) EAC* IG.22/7 and IG.23/6	UNEP/MAP (2011) BC Sed cores	BC Sur sed

* ERL. ERL for Naphthalene (160 μg/kg dw) and Total PAHs (4022 μg/kg dw) were derived by Long et al., 1995, but they do not appear in the COPs decisions

10. Further to this work, present document (Section 4) provides updated BC and BAC values for PAHs in sediment. They were calculated by using the new data and the same methodologies as applied in 2016 and 2019 for trace metals.

2.2.3 Naturally occurring trace metals (Cd, Hg and Pb) and organic compounds (PAHs) in biota[28]

11. Unlike the sediments, there are no values of the pristine, pre-industrial concentrations of naturally occurring compounds in biota. In 2011, the BC concentrations were computed based on the whole MEDPOL database (excluding known polluted stations), as the median of the lower 5% of the data. In 2016 and 2019, the BC concentrations were computed as for trace metals in sediments, based on the data sets from the selected reference stations. The calculated BC values for TM are presented in Table 3 for mussel and fish. The calculated BCs for PAHs in mussel are presented in Table 4. It should be emphasized that BC concentrations are species specific as well as tissue specific (i.e. natural concentrations in muscle are different from the natural concentrations in liver). In addition, BC concentration may depend on age of the specimens, with length and weight usually used as a proxy to age[29].

Table 3. Background concentrations (BC) calculated for trace metals in mussel and fish for the Mediterranean Sea and sub-regions in 2016 and 2019. The table also present the MedBAC and MedEAC values agreed upon in Decisions IG.22/7 and IG.23/6. Concentrations are given in the units requested by IMAP.

* EC, maximum levels for certain contaminants in foodstuffs based on European policy (EC/EU 1881/2006, 1259/2011 Directives and amendments 488/2014 and 1005/2015). # most data below detection limit. In red, sub-regional BC values higher than MedBAC (MedBAC= 1.5 MedBC, see Section 2.3.1)

12. Further to this work, present document (Section 4) provides updated BC and BAC values for TM in biota and PAHs in mussel. They were calculated using the new data and the same methodologies as applied in 2016 and 2019.

2.2.4 Synthetic substances (non-naturally occurring) in sediments and biota

13. The BC of any anthropogenic (man-made) substance is defined as zero. However, analytically, it is impossible to measure a concentration that equals zero. Therefore, the BC determination is based on the detection limits of the methods used and its uncertainty (precision and accuracy), as determined from CRMs (Certified reference materials) and proficiency testing. IMAP addresses organochlorinated compounds (PCBs and pesticides) as detailed in Table 5. This table summarizes the EAC values for the Mediterranean, agreed upon in Decisions IG.22/7 (COP19) and IG.23/6 (COP20). No BC nor LC (Low concentrations) were calculated for the Mediterranean in 2016 nor in 2019 (UNEP/MAP, 2016, 2019).

Table 5. EAC values for organochlorinated contaminants in sediments, in mussel (*Mytilus galloprovincialis*) soft tissue and muscle tissue in fish (*Mullus barbatus*) to be used in the Mediterranean Sea. The values were agreed upon in Decisions IG.22/7 and IG.23/6 and follow OSPAR's recommendations. Concentrations are given in the units requested by IMAP.

14. Further to this work, present document (Section 4) shows that the data were not sufficient to provide BC and BAC values for organochlorinated contaminants in sediment and biota.

2.3 The methodologies for thresholds` determination used by UNEP/MAP

15. UNEP/MAP has adopted the threshold assessment methodology, based on the "traffic light" approach, by defining 2 values to classify 3 environmental categories: 1) good (acceptable, not different from BC); 2) above background but with low risk for environment and biota population, or below dietary limits for fish and sea food concerning human health; and 3) unacceptable. The two values defined were i) the Background Assessment Concentration (BAC) (or T_0) and ii) the Environmental Assessment Criteria (EAC) for TM and organic contaminants in sediments and biota, or EC for TM and organic contaminants in biota, (or T_1). The above Tables 1-5 tabulate the values of BAC and EAC adopted or proposed to be used for the assessment of the quality status of the Mediterranean Sea (IMAP Decisions 22/7 (COP 19) and 23/6 (COP 20)).

2.3.1 Background Assessment Concentration (BAC) determination

16. BAC are the concentrations below which no deterioration of the environment can be expected. Observed concentrations are said to be near BC if the mean concentration is statistically significantly below BAC. For calculation of BAC values from BC concentrations UNEP/MAP adopted the methodology that corresponds to the OSPAR methodology. The BAC values were computed as the BC concentration multiplied by a factor that was determined based on the uncertainty (precision and accuracy) of the determinations. The multiplication factors were as follows: MedBAC=1.5 x MedBC (for mussel and sediment matrices); MedBAC=2.0 x MedBC (fish).

17. The MedBAC values endorsed in Decisions IG.22/7 and IG.23/6 are as follows: MedBAC for TM in sediments, mussel and fish (Tables 1,3) and PAHs in mussel (Table 4). In 2019, the same methodology was used to propose derivation of specific sub-regional MedBAC values.

18. Further to work undertaken in 2019, this document proposes updated regional and sub-regional BAC values for the Mediterranean, using the same methodology as in 2019. The proposed values are presented in Section 4.

2.3.2 Environmental Assessment Criteria (EAC) determination

19. EAC values are the concentrations above which significant adverse effect to the environment or to human health are most likely to occur. Conversely, EAC values are defined as the concentrations below which it is unlikely that unexpected or unacceptable biological effects will occur in exposed marine species. Due to that fact that it was not possible to develop EAC for MED at that time, it was agreed to use the criteria developed by OSPAR and NOAA/USEPA (ERL values) (Long et al. 1995), as the EAC values for the Mediterranean. The EAC values agreed in Decisions IG.22/7 and IG.23/6 are as follows: EAC values for TM, PAHs and organochlorinated contaminants (PCBs and pesticides) are provided for sediments in Tables 1, 2 and 5; TM and organochlorinated contaminants are provided for mussel and fish in Tables 3 and 5 and PAHs are provided for mussel in Table 4.

20. A proposal of a new methodology to derive EAC values specific for the Mediterranean Sea is described in Section 4.

2.3.3 European Union regulations (EC)

21. The EAC values for TM and PAHs in biota as endorsed by Decisions IG.22/7 and IG.23/6 (Table 3) are the concentrations in fish and seafood recommended as dietary limits for human consumption concerning human health (EC). EC values are derived from the following EU Directives regulating maximum levels for certain contaminants in foodstuffs: EC/EU 1881/2006, 1259/2011, 488/2014 and 1005/2015. Section 4.3 gives more details about EC values. It should be mentioned that these values were set up to protect human health and may be too lenient to protect the environment.

22. A proposal of new methodology to derive EAC values for the Mediterranean Sea is described in Section 4.

2.4 The assessment criteria for IMAP Common Indicator 18

23. By Decisions IG.22/7 and IG. 23/6, the Contracting Parties endorsed BAC and EAC values for the following biomarkers for the mussel (*Mytilus galloprovincialis*): Acetylcholinesterase activity (AChE), Metallothioneins (MT), Micronuclei frequency (MN), Lysosomal membrane stability (LMS-NRR and LMS-LP methods) and Stress on Stress (SoS). These values are indicative and serve as the initial assessment criteria.

24. Presently there are no new data that can be used to update the biomarkers` assessment criteria. Therefore, they were not addressed in Section 4. More information on biomarkers and related criteria derivation is given in UNEP/MAP WG.492/Inf 11.

3 Survey of relevant data not used previously neither for preparation of the Mediterranean Quality Status Report (2017 MED QSR) nor for the State of Environment and Development Report (2019 SoED)

25. New relevant data not used previously neither for the 2017 MED QSR nor for update of the assessment for EO9 within preparation of the 2019 SoED were collected from the following 4 data sources:

1. New data from IMAP Pilot Info System that include national monitoring data uploaded in the system during its testing phase, and in particular after launching formal call for reporting of data in June 2020.
2. New data from the MEDPOL Database not used previously for calculation of assessment criteria;
3. The EU data center (European Marine Observation and Data Network - EMODnet);
4. Published papers collected from the scientific literature.

26. Details of the available data from these sources are given below.

3.1 IMAP Pilot Info System and MEDPOL Database

27. Tables 6 and 7 provide a detailed examination of the new available data sorted by matrix, country and sampling year. The datasets used in the 2017 and 2019 assessments are given in UNEP/MAP WG.492/inf 11.

28. It can be seen that the IMAP and MEDPOL data included only TM and organic contaminants in sediment and biota (CI17). No new data were available for biomarkers (CI18). New biomarker data were not available also for assessments that contributed to 2019 SoED.

Table 6: An overview of available new data from IMAP Pilot Info System. The numbers next to the years are the number of observations for each parameter, sorted by country and sampling year. The number of below detection limit (BDL) observations is given in parenthesis.

3.3 Data from the scientific literature

30. Below Table 9 lists the available scientific papers used in the preparation of this document. It is important to note that the papers are usually limited in scope, both spatially and temporally. Moreover, they usually include contaminated and reference sites, so care should be taken when utilizing the data for BC calculation or verification. The search was geared towards finding recent data, from samples collected since 2012, and towards data from the southern Mediterranean countries. Detailed elaboration of relevant scientific literature is provided in UNEP/MAP WG.492/inf 11 (Annex 2).

Table 9. Data available from the scientific literature. The characterization of information provided in table is as follows: Data – all data could be retrieved from the paper; BC – paper specifies the background concentrations; Statistics – only statistics of the data are given (i.e. mean, standard deviation)

Country	Sampling year	Matrix	Parameter	Data	Reference
Algeria	2015	S	Cd, Pb	Statistics, BC	(Ahmed et al. 2018)

S-Sediment, B-Biota, ng- not given; *- data used for present update of BC/BAC values; **- data not used since were related to polluted sites

3.4 Examination of the new data

31. The new data available were examined and used for BC and BAC`s calculation, as appropriate. The computed values were then compared with the environmental criteria for the Mediterranean Sea as endorsed in Decision 23/6 (COP 20). Those are presented in section 4.

32. Data were very limited, therefore data from different years were aggregated per country and outliers identified (using box plots) and not considered in the calculation of the median values. When needed, data were transformed to the concentration units requested by IMAP. It should be mentioned that sediment data were not normalized.

33. In addition, for biota, it was not always clear if the concentrations were reported in dry or wet weight. When not specified, it was assumed that the data were reported to IMAP Info System/MEDPOL database as requested by IMAP.

34. This comparison was undertaken in order to confirm data relevance for computing the updated BC and BAC values (Section 4). An in-depth examination of the data is presented in UNEP/MAP WG.492/inf 11 (Annex 3).

4 Critical examination of recommended environmental criteria and proposals for their update

35. In line with Decision 22/7 (COP 19), the assessment criteria for the Mediterranean Sea should follow the "traffic light" system for both contaminant concentrations and biological responses where two thresholds and three status categories are defined. As explained above, the two values defined were the Background Assessment Concentration (BAC) (T_0) and the Environmental Assessment Criteria (EAC) or EC values (T_1), (see Section 2).

4.1 Updated BC and BAC values for IMAP CI 17

36. The new data presented and critically analyzed above in Section 3 were used to calculate BC values for the sub-regional areas of the Mediterranean and for the whole Mediterranean Sea using the same methodology as initially applied in 2016/2017 and replicated in 2019 (see detail explanation in Section 2). BAC values are calculated by multiplying the BCs by a factor, as follows: MedBAC=1.5 x MedBC (for mussel and sediment matrices); MedBAC=2.0 x MedBC (fish). When most of the data originated from one sub-region, and there were significant differences among them, the BC values were calculated for the sub-region(s) only.

37. Tables 10-12 present the new updated BC and BAC values. The tables include also the values of the assessment criteria as endorsed in Decision 23/6 (COP 20), as well as their values updated in 2019.

Table 10. BC and BAC values for trace metals in sediments, calculated from the new data. The table shows also the previously endorsed/updated values. Concentrations are given in µg/kg dry wt, as requested by IMAP. The number of data points (n) taken to calculate the BCs appear below the values.

BCs							
TM	Med (cores)	Med (surf)	Med	WMS	ADR	CEN	AEL
	2011[31]		**2019**				
Cd	100	20	85	91.2	92.3		56
Hg	30	10	53	60	106.8		31.2
Pb	20000	2310	16950	20465	13932		4920
Proposed new updated BC values (2021)							
Cd			116	115	166		113

[31] The values calculated in 2011 are shown for comparison. The values were calculated from data compiled from the scientific literature (UNEP/MAP 2011) and need no recalculation

n			135	*56*	*41*		38
Hg			32.6	25.0	54.1	2-69*	50.3
n			113	*33*	*37*	*6*	37
Pb			15900	12000	27066		17700
n			229	*58*	*44*		127
BACs							
		IG.23/6	Med	WMS	ADR	CEN	AEL
		2017	**2019**				
Cd		127.5	127.5	136.8	138.5		84.0
Hg		79.5	79.5	90.0	160		46.8
Pb		25425	25425	30698	20898		7380
Proposed new updated BAC values (2021)							
Cd			158	173	249		169
Hg			49.2	37.5	81.2		75.5
Pb			24269	18000	40599		26550

38. It can be seen that the updated regional Mediterranean BC values for Cd and Hg are very similar to the ones calculated in 2011 from sediment cores while value for Pb is lower. Comparison to the BCs values updated in 2019 shows that presently updated regional BC values for Cd is higher, Hg is lower and Pb slightly lower (4%). Comparison of the sub-regional BC values calculated in 2019 and 2021 shows differences as well. Possible reasons for these differences could be due to different sediment mineralogical composition and the location of the sampling stations. In addition, for the regional BC values, an unbalanced number of data points among the sub-regions taken for the calculation, possibly gives an unproportionate weight.

Table 11. BC and BAC values for PAHs in sediments, calculated from the new data. The table presents also the previously endorsed/updated values. Concentrations are given in mg/kg dry wt, as requested by IMAP. The number of data points (n) taken to calculate the BCs appear to the right of the values. No data were available for the AEL sub-region.

Total PAHs			248		249		327		9.9	

39. Concentrations of PAH compounds in the sediments were available for 29 - 44 data points, while for Total PAHs, 71 data points were available. The calculated BC values for some of the compounds were higher than the BC concentrations measured in sediment cores and surficial sediments of the Mediterranean Sea in 2011, while for other compounds they were similar. This could be due to the limited number of datapoints used for the calculation both in 2011 and 2021. Therefore, it is proposed to use presently updated values of BC/BAC for preparation of input assessments for 2023 MED QSR, along with further update of the assessment criteria if more data will be reported by the CPs[32]. Moreover, it is recommended to add the concentration of Total PAHs to the list of parameters.

Table 12. BC and BAC values for trace metals in mussel (*M. galloprovincialis*) and BC values for trace metals in other biota species calculated from the new data[33]. The table presents also the previously endorsed/updated values. The units of concentrations are given as requested by IMAP. The number of data points (n) taken to calculate the values appear below the values.

[32] The values for a few of the compounds in Table 11 are 0, meaning that the concentrations measured were BDL. Paragraph 46 below addresses the topic of BDL concentrations.

[33] BAC values were calculated just for *M galloprovincialis*. Data for the other mandatory species (*M. barbatus*) were not enough to calculate Med BACs. To calculate BACs from the BCs the following factors should be applied: BAC=1.5 x BC (mussel); BAC=2.0 x BC (fish).

#MedBAC in Decision IG.23/6; * Most values BDL; ^ questionable values, may be related to hot spot stations, therefore not taken for the calculation of regional MedBC; > it is recommendation to use the values calculated in 2019.

40. The regional MedBC values for Cd, Hg and Pb in *M. galloprovinciallis* calculated in 2021 were lower than those calculated in 2019. The subregional BCs for the WMS and the ADR were also different: WMS BC for Cd was higher and for Pb lower in 2021 compared to 2019, while WMS BC for Hg was similar. In the Adriatic the BC concentrations were much lower in 2021 than in 2019: ADR BC for Cd and Pb decreased by about one order of magnitude, while for Hg it was about 3 times lower. The differences in the Adriatic could be due to different locations of the sampling stations and to a temporal decrease. However, the most important point is the differences in concentrations between the WMS and the other sub-regions. The BC concentrations in the WMS were much higher for all three trace metals. Therefore, it is recommended to use the sub-regional BCs for *M. galloprovinciallis*. Since new data were not available in the AEL to update BC/BAC values for *M. galloprovinciallis*, it is recommended to use the values calculated in 2019. Comparison of BC concentrations calculated in 2021 for Cd and Pb in M. barbatus from the AEL to the BCs in Decision IG23/6 showed that they are

[34] *C. chione* in the WMS, *ML and R.ruditapes* in the CEN, *M.corralina* in the AEL. See section 4.
[35] *S. pilchardus, B. boops, T. trachurus, S. sphyraena, D. annularis, P. acarne, P. erythrinus, M. barbatus, M. surmuletus, S. notata, S.scrofa, C. conger, D. sargus, L. mormyrus, S. rivulatus, S. rubrum.* See Section 3.

low and similar. Calculated Hg concentrations calculated in 2021 were lower than the concentration in Decision IG23/6

41. The mussel *M. galloprovinciallis* and the fish *M. barbatus* are agreed as IMAP mandatory species. However, they may not be always found in all the areas of the Mediterranean Sea. Therefore, the addition of other (mandatory area specific) species to the monitoring program is recommended for further consideration. The species should be chosen based on their presence in the sub-regions, and relevance as pollution indicators, what will allow a better environmental assessment. Data from different species are presented in Table 12. It should be noted that the concentrations measured are specific to each species and comparison should be made within the same species (see Section 2).It may be useful to consider in the future an upgrade of IMAP in order to include larger number of species.BC concentrations of organochlorinated contaminants (PCBs and pesticides) in sediments and biota were not calculated either in 2011, 2016 or in 2019. The availability of new data is not sufficient to calculate BC values for these contaminants (see section 3).

42. For determination of BC values for CI17, the following key findings can be provided:

- For some parameters there is a marked difference among the Mediterranean sub-regions. Therefore, it is proposed in those cases (i.e. Pb in sediments, Cd and Pb in *M. galloprovincialis*, sum of PAHs in sediments), to consider using the sub-regional Mediterranean Sea assessment criteria.
- A statistical treatment of BDL data should be agreed upon. It is recognized that the different BDLs make it hard to use half of the BDL concentration for these values. However, it is not reasonable not to take BDL values into consideration.
- An in-depth examination of more data points, that need to be reported by CPs, should be performed in particular when large differences were observed between the BC values calculated in 2016 and in 2021. This is true for TM in sediment and biota in all sub-regions. The examination should include, among others, characterization of the stations used (hot spot, reference, other), analytical methodology, normalization, temporal trends.
- For the other parameters, such as PAHs in biota, and organochlorinated contaminants in sediment and biota, new additional data are needed to recalculate the BCs. Before new data availability will allow their recalculation, present values remain valid for preparing assessment inputs for the 2023 QSR.

4.2 An upgraded approach for updating EAC values for IMAP CI 17

43. As explained above (see Section 2), the EAC values endorsed for use in the Mediterranean Sea were NOAAs ERLs (for TM, PAH and pesticides in sediments) and the ECs from EU Directives to protect human health (for TM and organic contaminants in biota). They may be too lenient if the goal is to achieve and maintain GES where the contaminants cause no significant impact on coastal and marine ecosystems. However, EAC values cannot be updated based on existing monitoring data. It needs a very specific in-depth research of the ecotoxicological and environmental scientific literature.

44. Therefore, the methodology detailed in European Commision Guidance Document (2018) and in Long et al. (1995) is recommended for the update of Mediterranean EAC values. It includes a thorough examination of the scientific literature conducted to study where data on no effect or adverse biological effects are given in conjunction with chemical data in the environment and in the biota at the same site and time. Those include but are not limited to sediment toxicity tests, aquatic toxicity tests in conjunction with equilibrium partitioning (EqP) and field and mesocosm studies. The data should be assembled into a detailed database and analyzed, as well as the extent of the effect determined. The emphasis should be given to Mediterranean biota species.

45. Upgrade of the EAC values for Mediterranean Sea as recommended above is a long-term task that needs a dedicated, very specific, scientific research.

4.3 Proposal of new EAC values for IMAP CI 20

46. Proposal of the EAC values for IMAP CI 20 related to actual levels of contaminants that have been detected and number of contaminants which have exceeded maximum regulatory levels in commonly consumed sea food is based on a survey of existing sources, including Directives of EU related to the maximum permitted levels for contaminants in fish and seafood for the protection of human health. Table 13 details the concentrations cited at different sources for TM (Cd, Hg and Pb) and for organic contaminants (PCBs, dioxin).

47. From Table 13 it is possible to see that the criteria are taxa specific (fish, mussel, crustacean), as well as species specific. For example, maximum allowable Hg concentration in fish muscle is 0.5 mg/kg ww, excluding listed species such as bonito, marlin, halibut, mullet species, among others, in which the maximum allowable Hg concentration in the muscle is 1.0 mk/kg ww (see EC/EU Directive 1881/2006).

48. In addition, Decision IG.23/6 details the indicative regional EAC values for PAHs in mussels (*Mytilus galloprovincialis*) and for organic contaminants in mussel (*Mytilus galloprovincialis*) and fish (*Mullus barbatus*) that are considered biota matrix of IMAP Common Indicator 17. These values are given in Tables 4 and 5. As these values were set up to protect human health, they may be too lenient to protect the environment (see paragraph 22). However, since the values are based on the maximum levels for certain contaminants in foodstuffs as provided in EC/EU Directives 1881/2006, 1259/2011 and amendments 488/2014 and 1005/2015, they are proposed to be also used for IMAP CI 20.

Table 13. Compilation of maximum levels for trace metals in fish and seafood for the protection of human health[36]. The concentrations are presented in mg/kg ww.

Source	**matrix**	**Cd**	**Hg**	**Pb**
		mg/kg ww

49. The maximum levels of organic contaminants in fish and seafood for the protection of human health are as follows: NOAA, 0.5 and 2 PCB (mg/kg ww) in fish and other seafood, respectively; EU Directive 1881/2006, 2-5 and 6 (mg/kg ww) of benzo(a)pyrene and 12-30 and 35 (mg/kg ww) for the

[36] The following sources are used in Table 13 and paragraph 52:
NOAA (National Oceanic and Atmospheric Administration) tabulation of the export requirements by country for fish and seafood (among others) (https://www.fisheries.noaa.gov/export-requirements-country-and-jurisdiction-f). Requirements by Australia, Brazil, Chile, China and Equador for trace metals;
EU directives for maximum levels for certain contaminants in foodstuffs (EC/EU 1881/2006 , 1259/2011 Directives and amendments 488/2014 and 1005/2015);
CODEX Alimentarius international food standards, guidelines and codes of practice. Joint FAO/WHO Food Standards Programme .

sum of benzo(a)- pyrene, benz(a)anthracene, benzo(b)fluoranthene and chrysene in smoked fish muscle and on smoked bivalve mollusc, respectively; EU Directive 1259/2011 – 3.5 pg/g ww for the sum of dioxins in fish muscle and liver and in eel muscle; 6.5, 10 and 20 pg/g ww for the sum of dioxins and dioxin like PCBs in fish muscle, in eel muscle and in fish liver, respectively; and 75, 300 and 200 ng/g of the sum of PCB28, PCB52, PCB101, PCB138, PCB153 and PCB180 in fish muscle, in eel muscle and in fish liver, respectively. As for TM, the maximum allowable concentrations are taxa specific.

50. The values as established by above EU Directives are submitted for consideration to present meeting in order to guide the Secretariat and the Parties on their application as EAC values for IMAP CI 20. These values are in the low and mid-range of criteria used around the world and has the advantage to be consistent with regulations of EU. Their consistent application across the region is necessary. It should also be highlighted that these values were agreed at EU level also considering the ecosystem characteristics of Mediterranean Sea.

4.4 The way forward

51. As indicated in this document the work on the assessment criteria is a long way that requires very good quality of data and long time series. There is good progress in the last ten years in developing the assessment criteria, whereby better progress for BC/BAC has been achieved than for EAC. There is room to further reflect on how to upgrade work for calculation of Mediterranean EAC values for IMAP CIs 17 and 18, including by creating a database of scientific literature, as a long-term task, with support of the Online Working Group (OWG) for Contaminants (EO9), in order to complement real-time monitoring data to be reported from the Contracting Parties into IMAP Pilot Info System.

52. Scientific and expert contribution of the OWG for Contaminants is necessary to ensure analysis of the proposed updated sub-regional and regional BC and BAC values, against the new data that are expected to be provided by the members of the OWG or all the Contracting Parties in the IMAP Info System.

53. The criteria presently used for IMAP assessments are single parameter criteria. Each parameter is analysed separately to decide if the concentration is above or below the threshold. In view of the preparation of the assessment inputs for 2023 MED QSR, it is recommended to aggregate thresholds, that would better describe the environmental status and be a step towards determination of the overall environmental status. To that effect the NEAT and CHASE+ approaches should be considered, taking also into account their additional merit to achieve consistency with the EU MSs (see UNEP/MED WG.492/Inf. 11).

Appendix 8

Assessment Criteria Methodology for IMAP Common Indicator 13: Pilot Application in Adriatic Sub-region

Introduction

Eutrophication is a process driven by enrichment of water by nutrients, especially compounds of nitrogen and/or phosphorus, leading to: increased growth, primary production and biomass of algae; changes in the balance of nutrients causing changes to the balance of organisms; and water quality degradation (IMAP, 2017[37]). Seawaters depending on nutrients loading and phytoplankton growth are classified according to their level of eutrophication. Low nutrient/phytoplankton levels characterize oligotrophic areas, whilst water enriched in nutrients is characterized as mesotrophic and water rich in nutrients and algal biomass is characterized as eutrophic.

Good environmental status (GES) with regard to eutrophication is achieved when the biological community remains well-balanced and retains all necessary functions in the absence of undesirable disturbance associated with eutrophication (e.g. excessive algal blooms, low dissolved oxygen, declines in sea-grasses, kills of benthic organisms and/or fish) and/or where there are no nutrient-related impacts on sustainable use of ecosystem goods and services. Specifically, for IMAP Common Indicator 13 related to key nutrients in water column GES is achieved when concentrations of nutrients in the euphotic layer are in line with prevailing physiographic, geographic and climate conditions.

Coastal waters (CWs) are among the most highly impacted ecosystems in the world presenting inherently high variability over both spatial and temporal scales (Reyjol et al., 2014[38]). In those environments, the greatest impacts of increasing nutrient concentrations have been observed at sites with restricted water exchange, resulting in phytoplankton and macroalgal blooms (Tett et al., 2003[39]; Teichberg et al., 2010[40]).

A significant amount of research has been done in developing and intercalibrating biological indicators to assess impact of eutrophication in coastal waters (Borja et al., 2013[41]). Phytoplankton is the most suitable for assessing eutrophication due to direct response to nutrient conditions (Devlin et al., 2007[42]). However, less attention has been directed to linking ecological status to management actions and establishing meaningful and consistent nutrient criteria to support achievement of GES (Hering et al., 2015[43]).

The European experience is relevant in the field. A comparison of nutrient boundaries set for the Water Framework Directive (WFD) and the Marine Strategy Framework Directive (MSFD) in transitional, coastal and marine waters across EU Member States (Dworak et al., 2016[44]) revealed a huge variability in nutrient concentrations boundaries, but also in other relevant aspects such as the nutrient parameters and metrics used, the time of year assessed, the reference conditions established. It also revealed that often MSs` boundary values of nutrient concentrations do not follow relevant Regional Seas Conventions (RSCs) nutrient standards.

The possible implications of the wide variations in the nutrient concentration boundaries need to be understood in the context of establishing appropriate nutrient boundaries to achieve GES. A Best Practice Guide (BPG, Phillips et al., 2018[45]) has been elaborated in this context. Its purpose is to help in achieving GES in surface waters. It complements previous guidance on eutrophication assessment (EC, 2009[46]) by providing more targeted advice on how to link nutrient concentrations in surface waters to specific policy objectives. The new guide includes a tool kit to facilitate the application of the different statistical approaches proposed to establish the nutrients` targets.

The statistical approaches proposed in the BPG in coastal and transitional waters focus on the pressure-response relationships found between the nutrients and phytoplankton. Most of the EU MSs use the concentration of Chlorophyll a (Chl *a*) as a proxy measure for phytoplankton biomass within intercalibration, whereas most of the indicators of other sub-elements (phytoplankton composition and blooms) have not yet been intercalibrated (Garmendia et al., 2013[47]). This corresponds to monitoring of IMAP Common Indicator 13 (i.e. concentration of key nutrients in water column) and Common Indicator 14 (i.e. concentration of Chl *a*) that does not define the criteria/sub-indicators related to the harmful algal bloom; photic limit (transparency) of the water column; relative abundance or depth distribution of macrophyte communities; as well as the species composition and relative abundance of macrofaunal communities, as mandatory parameters within IMAP implementation.

Nitrogen or phosphorus limitation

All sub-indicators/parameters related to IMAP CIs 13 and 14 are monitored or have been defined for regular monitoring within implementation of recently prepared national IMAP Pollution Cluster monitoring programmes. The temporal scales are well harmonized among Parties. Only two Parties have already defined the scales according to the type of waters and the rest will do so during the 1st implementation phase.

However, in the Mediterranean region there are many differences in the nutrients` parameters assessed, the assessment period (summer, year-round, i.e. annual), and in the statistic used (mean, median or 90th percentile) within assessment of the conditions of saline waters. These differences can be also observed within the four marine ecoregions defined by the MSFD and even between transitional, coastal and marine waters at national levels (Dworak et al., 2016).

In general nitrogen, rather than phosphorus, is considered to be the most likely limiting nutrient in many temperate coastal waters (Tsirtsis, 1995[48]). However, for the Mediterranean area it is the opposite and can be summarised as presented here-below.

In the Mediterranean phosphorus is often the limiting nutrient (Lazzari et al., 2016[49]; Thingstad et al., 2005[50]), although it is closely followed by nitrogen in this limiting role (Estrada, 1996[51]). The dissolved nitrogen to phosphorus ratio in the Mediterranean has been reported at about 21 to 23 in the

[51] Estrada, M. (1996). Primary production in the Northwestern Mediterranean. Sci. Mar. 60, 55–64.

western part (Bethoux et al., 1992[52]), and even higher in the eastern basin (Krom et al., 1991[53]), which is quite different from the ratio of 16 found in the global ocean (Tyrrell, 1999[54]).

This has been proved by the model-based reconstruction of inorganic phosphate and nitrate distributions presented by Lazzari et al. (2016). The model demonstrated that when nutrient limitation occurs, in the vast majority of cases, phosphorus is the limiting nutrient, with the notable exception of the Alboran Sea, which is mainly nitrogen limited, and the southwest basin, in which both nitrogen and phosphorus can limit plankton growth. Ramirez et al. (2005[55]) showed nitrogen-limitation in the upper layers (first 20 m) of the north-west Alboran Sea during the winter, summer and autumn while Dafner et al. (2003[56]) suggested phosphorus limitation in the Strait of Gibraltar area. However, phosphorus limitation in the upper layers of this area is not due to very low phosphorus concentrations but rather to a very high Nitrogen:Phosphorus (N:P) ratio in the area east of Gibraltar, caused by the upwelling of deep Mediterranean waters. The Adriatic Sea is mostly phosphorus-limited (Rinaldi, 2014[57]). Along the coast of the northern and central Adriatic Sea, 90 % of the overall chlorophyll *a* variability is explained by Total Phosphorous (TP) (Giovanardi et al., 2018[58]). The high N:P ratios in the Adriatic Sea (>50) demonstrate that nitrogen does not limit algal growth. The Po River has a major effect on the whole Adriatic basin, determining patterns of both spatial and temporal variation.

Total or inorganic dissolved fraction, assessment period and statistics

During phytoplankton blooms, dissolved inorganic nutrients in surface layers may be almost completely consumed, leading to nutrient limitation at periods of peak of biological activity. This results in large seasonal variability of nutrients` concentrations. For this reason, Dissolved Inorganic Nitrogen (DIN) and Dissolved Inorganic Phosphorus (DIP) are usually measured and assessed when biological activity is lowest.

Total Nitrogen (TN) and Total Phosphorus (TP), which include all forms of nitrogen and phosphorus compounds, are also important parameters that should be assessed in addition to the dissolved nutrients, as it is already common practice for example by HELCOM and in Swedish, Finnish and Estonian coastal waters (HELCOM, 2009[59]). Adding total nutrients alongside inorganic nutrients, as core indicators, strengthens the link from nutrient concentrations in the sea to nutrient enrichment. These parameters may also allow consideration of climate change in the eutrophication assessment since higher temperatures will lead to year-round phytoplankton proliferation and/or possible changes in zooplankton communities.

In addition, there are other considerations that are not directly linked to setting of nutrients` thresholds but that are nevertheless important. Total nutrients are essential for determining nutrient budgets (i.e. an estimation of how much nutrient enters and leaves an area). Such budgets have particular

importance in coastal and marine waters that are influenced by transboundary nutrients` transport and receive nutrients` inputs from other countries.

Furthermore, total nutrients are also essential parameters for establishing nutrient reduction targets. This means that monitoring and assessing both total and dissolved nutrients forms is necessary for good understanding of the trend in nutrients` concentrations in the marine environment. However, within present monitoring of eutrophication, both within implementation of IMAP and MSFD, the measurement of all total (TN, TP) and dissolved (ammonia, nitrite, nitrate, orthophosphate, orthosilicate) forms are requested, in order to allow the calculation of all aggregated form as DIN and DIP.

To enable a consistent management approach, it is important to ensure a consistency between transitional, coastal and marine waters, at least within a region or subregion, in relation to monitoring and assessment of nutrients` parameters.

A final consideration is the choice of statistical measures used to aggregate nutrients` samples from a chosen assessment period in order to determine the concentrations of monitored parameter/indicator. Most of the Regional Seas Conventions use mean concentrations to ensure cross-comparisons. However, there might be cases where using the median is more robust, since it is less influenced by outliers. The choice of the appropriate statistics depends very much upon sampling size and quality of monitoring.

Since statistical distributions of chlorophyll *a* and nutrients tend towards log-normality, the parameter that better estimates the value around which central clustering occurs, is represented by the geometric mean, i.e. the arithmetic mean of log-data reconverted into numbers. The normalization of the data distributions by means of log transformation stabilizes the variance, with a standard deviation (sd) practically constant in the case of decimal log-transformation (Giovanardi and Tromellini, 1992[60]). These statistical properties indicate that the use of the annual geometric mean of data as the metric for setting the assessment criteria in Mediterranean is appropriate statistical measure.

Further to above considerations and given limited data availability as presented here-below, present document paves the way for calculation of the reference conditions and boundary values for Dissolved Inorganic Nitrogen (DIN) and Total Phosphorous (TP).

Data availability

The elaboration of data availability for calculation of the assessment criteria for DIN and TP includes the following 3 sources*:*

1) New data from IMAP Pilot Info System that include national monitoring data reported during its testing phase, and in particular after launching formal call for data reporting in June 2020;
2) All monitoring data from MEDPOL Database (i.e. data reported before 2012 that were uploaded into MEDPOL Database along with data reported to MEDPOL outside MEDPOL Database in the format of old metadata templates in period 2013-2019) that are in the process of their migration into IMAP Pilot Info System;
3) The EU data center (European Marine Observation and Data Network - EMODnet).

IMAP Pilot Info System and MEDPOL Database

A summary of both data reported both to IMAP Pilot Info System and MEDPOL Database are presented in Table 1.

[60] Giovanardi, F., Tromellini, E., 1992. An empirical dispersion model for total phosphorus in a coastal area: the Po River-Adriatic system. Sci. Total Environ. Supplement 201–210.

*Both validated and not validated data have been used for assessing sources for calculation of the assessment criteria for DIN and TP, given temporary not validated status may be assigned to data due to certain technical issues in IMAP Info System

It can be concluded that data available for calculation of the assessment criteria (i.e. reference conditions (RCs) and boundary values) for both DIN and TP are insufficient. Namely, for calculation of the RCs and boundary values as a minimum the following datasets need to be provided: three continuous years of monitoring with a minimum monthly frequency for Water types I and II and bimonthly to seasonal for Type III. It should also be noted that other supporting parameters (i.e. temperature, salinity and dissolved oxygen) need to be available for defining the water typology,

Data available in the EU data center (European Marine Observation and Data Network - EMODnet)

Given scarcity of data reported into IMAP Pilot Info System and MEDPOL Database, data availability in EMODnet has also been explored (Table 2). However, it must be noted that EMODnet data are limited only to Croatia, France, Greece, Israel, Italy, Montenegro, Spain, Tunisia and Turkey. There is also different format of EMODnet data compared to data reported into IMAP Pilot Info System. Therefore, a significant further work is needed to correlate and aggregate two data sources.

Table 2: Datasets for Chlorophyll *a* and nutrients available at EMODnet, for period 2015-2020.

Country	Total available data	Unrestricted
Croatia	429	-
France	2344	493
Greece	229	-
Israel	29	29

Italy	2156	1247
Montenegro	146	-
Spain	244	-
Tunisia	29	-
Turkey	726	180

In line with above elaborated data availability, the following Mediterranean sub-regions/sub-areas may be indicated for calculation of the reference conditions and boundary values for DIN and TP: Adriatic, North Western Mediterranean Sea, Tyrrhenian Sea, Aegean Sea and Levantine Sea. They are proposed also considering the areas that were initially proposed for calculation of the assessment criteria for contaminants[61]. This can be considered the initial phase for establishing reference conditions and boundary values for nutrients, whereas the values can be proposed for entire Mediterranean upon data reporting from CPs that will fill present data gaps.

Online Working Group for EO5 needs to substantively contribute to increased data availability and statistical calculation of data in above indicated areas.

The calculation of the assessment criteria for DIN and TP in Adriatic Sub-region

The scientific experience related to eutrophication in Adriatic Sea is huge and relay on the problems derived from the eutrophic pressure connected with the Po River watershed where live around 16 000 000 inhabitants. Near the scientific experience also a huge data set exists that enabled development of TRIX (Volenweider et all., 1998[62]), an index for the assessment of the eutrophication, and a regional approach for development of classification criteria based on Chlorophyll *a* within IMAP (Giovanardi et al, 2018).

This ensures further development of a harmonized approach to the definition of reference conditions and boundary values for DIN and TP based on the relationship between pressure and responses. To that effect the necessary steps are presented here below, whilst detail elaboration of this approach is provided in UNEP/MED WG.492/Inf.12 submitted for information of present Meeting.

Water typology

The Water typology is very important for further development of classification schemes of a certain area. The major coastal water types and related criteria in the Mediterranean were defined following on their inter calibration, that was applicable for phytoplankton only, as provided in Decision IG.22/7 on IMAP (COP 19, 2016[63]).

The water typology, a parameter having a robust numerical basis, can describe the dynamic behaviour of a coastal system. The assessment criteria are built per Water types that are mainly focused on hydrological parameters and characterization of water bodies' dynamics and circulation/ They are based on the introduction of density, the static stability parameter (derived from temperature and salinity values in the water column) for characterising of water bodies.

The first step in setting reference conditions and boundary values for an area i.e. Adriatic Sea sub-region is to identify present Water types and to attribute the data related to the density or salinity boundaries (Table 3).

---

[61] The Mediterranean sub-regions and subareas are initially proposed according to availability of database sources for calculation of the assessment criteria for contaminants (UNEP(DEPI)/MED WG.427/Inf.3; UNEP/MED WG.463/8; UNEP/MED WG.467/7).

Table 3. Major coastal water types relevant for Adriatic Sea with density and salinity boundaries

	Type I	Type IIA, IIA Adriatic	Type IIIW
σ_t (density)	<25	25<d<27	>27
S (salinity)	<34.5	34.5<S<37.5	>37.5

Reference condition

Reference Conditions (RCs) represent "a description of the biological quality elements that exist, or would exist, at high status". That is, with no, or very minor disturbance from human activities. The objective of setting reference conditions` standards is to enable the assessment of ecological quality against these standards (WFD CIS Guidance Document No. 5 (2003[64])).

An acceptable approach is to use a comprehensive pressure indicator that is able to address the potential transport of nutrients (natural loads plus anthropogenic loads) from the mainland to the sea, and that also measure, albeit roughly, this transport verifying the eventual absence of pressures of some importance exerted by human activities. For this purpose, use of dilution factor is considered as it was the case when the RCs for the Adriatic and Tyrrhenian Sea were developed (Giovanardi *et al.*, 2018).

The dilution factor is formulated as follows: F_dil=[(S-s)/S]*100, where S = open sea salinity, s = measured salinity at a given coastal sampling point (Giovanardi and Vollenweider, 2004[65]).

The role of the F_dil factor in assigning the chlorophyll *a* RCs is depicted in Figure 1.

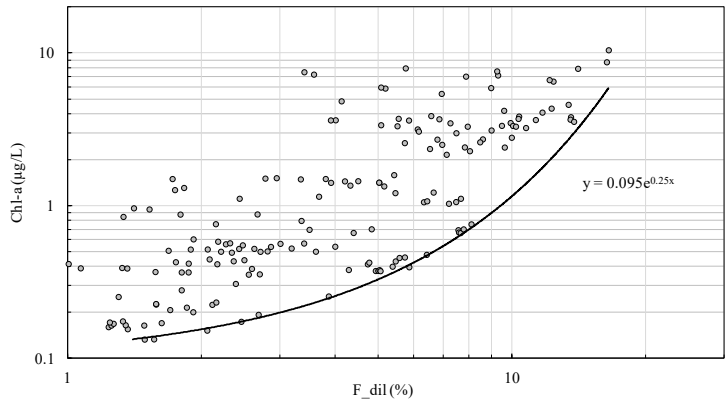

Figure 1. Scatter plot of annual *G_means* of chlorophyll *a* (Chl-a) against the dilution factor (F_dil) for Types I and II A. The curve marks the boundary of the lower limit of chlorophyll *a* reference conditions values (RCs). Original Figure from Giovanardi *et al,* 2018.

This separation line can be interpreted as the threshold between natural and anthropogenic pressures. It is assumed that the nutrient loads, either natural or generated by minor human activities, determine a response of the coastal systems that is well-represented by concentrations of chlorophyll *a* lying on the curve (Figure 1). Thus, the assessment of RCs does not derive from theoretical considerations or expert judgments but refers to real situations occurring along the Adriatic coast.

The same approach cannot be used for the nutrients, given the dilution factor represents an integrated measure of the nutrient's pressures to the ecosystem. However, defining the reference conditions for chlorophyll *a* for different water types, precedes to setting of the reference conditions for nutrients,

[64] WFD CIS Guidance Document No. 5 (2003) Transitional and Coastal Waters Typology, Reference Conditions and Classification Systems.
[65] Giovanardi, F., Vollenweider, R.A., (2004). Trophic conditions of marine coastal waters: experience in applying the Trophic Index TRIX to two areas of the Adriatic and Tyrrhenian seas. J. Limnology 63, 199–218.

whilst the nutrients RCs will be derived from the pressure to effects relationship as presented here-below.

In order to define more accurately chlorophyll *a* RCs for each water type, the data corresponding to individual Adriatic types were considered separately. Then it was possible to plot the curves separately for all types (Figure 2), which represent the RCs for each type.

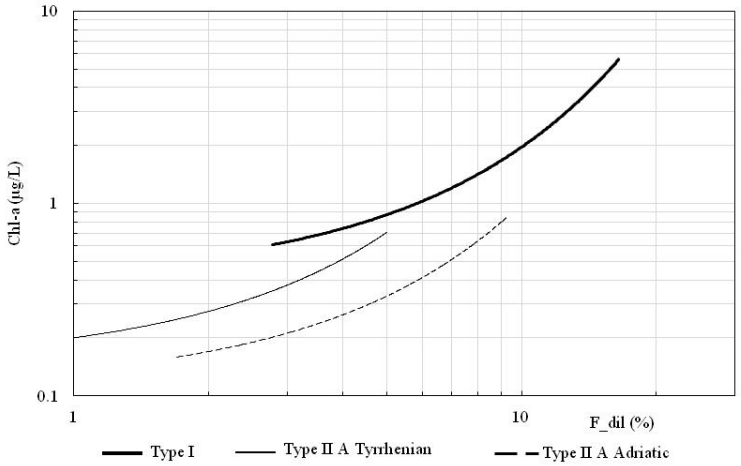

Figure 2. Reference conditions for chlorophyll *a* (Chl a) corresponding to different water types, depending on the gradient of the dilution factor (F_dil). Original Figure from Giovanardi *et al,* 2018.

The best functional relationships between chlorophyll *a* RC and F_dil were always exponential. The equations describing these relationships have been used to derive a unique chlorophyll *a* RCs per water types corresponding to the mean value of F_dil. Table 4 summarizes the results.

Table 4. Summary table for BQE phytoplankton reference conditions (RC) based on chlorophyll *a*.

Type	Functional relationships	F_dil (%) *Mean value*	RC - Chl-a (µg/L) as *G_Mean*
Type I	$y = 0.388\ e^{0.162x}$	7.9	1.40
Type II A Adriatic	$y = 0.109\ e^{0.221x}$	4.96	0.33

Pressure to effect relationship

Defining pressure to effect relationship is critical for nutrients RCs setting. Furthermore, a complete understanding of the functional relationship which links pressures to ecological effects result at the end with the programmes and measure as the final goal of the assessment process. To define the pressure to effect relationship, there is a need to apply relevant statistical analyses.

First the sensitivity of the selected metrics to different pressure indicators, with multiple regression analysis with linear models (LMs), was performed. By means of this stepwise regression technique, the variations of chlorophyll *a* concentration were tested against the pressure indicators available in dataset for Adriatic Sea (i.e. nutrient concentrations, oxygen saturation, dilution factor and Secchi depth). Annual geometric means of the parameters were used for this analysis.

The statistical analyses were performed using statistical packages offered by the program R and the exact statistical procedure is explained in UNEP/MED WG.492/Inf.12[66] submitted for information of present meeting.

Data processing involved the use of techniques of regression analysis provided by the package *stats*. For Type I among all the possible combinations, the stepwise regression technique provided the following linear model:

lm (formula = Chl-a ~ F_dil + aD_O + TP + DIN, data = Type_I)

The fitted linear model explains 89% of the total chlorophyll *a* variability and the maximum weight in determining this variability accounts to TP.

For Type II A coastal water the linear model provided by the stepwise regression technique was:

lm (formula = Chl-a ~ F_dil + TP, data = Type_II A)

The linear model is quite simple. Only two regressors were chosen with a largely dominant weight of TP over the weight of F_dil and the amount of chlorophyll *a* variability explained by this model is 78%. As TP accounts for the maximum weight in determining the variability of chlorophyll *a*, for both Type I and Type II A Adriatic, this parameter can be considered as the most eligible indicator of the pressure gradient. In this case the phosphorus pool in the water column (TP) can be considered as an internal measure of external phosphorus enrichment.

The above calculated relationships showed that chlorophyll *a* sensitivity, considered as the response of coastal systems to the availability of nutrients in terms of phytoplankton biomass production, is largely controlled by total phosphorus, which can therefore assume the role of the main pressure indicator.

The important regression equations used subsequently for the construction of the ecological classification criteria are summarized in Table 5.

Table 5. List of functional relationships of interest per water types. For each regression equation, the sample size N and the R-squared values are provided.

Functional link	Type I	Type II A Adriatic
1.TP vs TRIX	[TP] = exp [(TRIX – 6.064)/1.349] N = 15	[TP] = exp [(TRIX – 6.148)/1.583] N = 52
2. Chl-a *vs* TP	[Chl-a] = 10.591 [TP] $^{1.237}$ N = 15; R^2 = 0.835; *P* = 4.45 10^{-6}	[Chl-a] = 3.978 [TP] $^{1.347}$ N = 52; R^2 = 0.896; *P* = 2.2 10^{-16}

The nature of these relationships is almost always *log-log* type, which provides the highest degree of correlation. The equations in row 1 were obtained from the inverse relationship between the TRIX index and its component TP. For Type I and II A Adriatic these equations were prepared separately per water type, using the same data as those used to assess the functional relationships between TP and chlorophyll *a*. Finally, equations in row 2 exploit the relationship between TP and chlorophyll *a*, with the aim of fixing the limits among the ecological quality classes of the classification criterion, both for RCs and boundaries values.

The DIN was not elaborated further as the stepwise regression (i.e. the linear models) showed that it is not explaining the variability of the chlorophyll *a* and precise boundaries for DIN cannot be set.

Boundaries setting

With the definition of nutrients` RCs for Type I and Type II A coastal waters and the unveiling of their pressure-impact relationships, all the necessary tools are provided for defining the classification

[66] UNEP/MED WG.492/Inf.12. Analysis of the Methodologies Available for Establishment of the Assessment Criteria for IMAP Common Indicator 13.

criteria for Biological Quality Element (BQE) phytoplankton in Adriatic coastal waters. Given the Trophic Index (TRIX, Vollenveider et al, 1998) was developed first for the northern Adriatic and it ecological use is well known, it was used as an internal scale in setting the boundaries.

The first step was to calculate the RCs for type I and Type II Adriatic from the functional relationship between Chla and TP (Table 5, row 2) and resulting in 0,19 µmol/L and 0,16 µmol/L, respectively.

The next in setting the boundaries was the definition of the most important boundary i.e. the Good/Moderate (G/M) boundary, which delimits the need for taking measures in case of good ecological status failure. Firstly, the boundary was set for TP, as it appeared to be the best pressure indicator for phytoplankton as explained above. The G/M boundary for TP was calculated using the equations in row 1 of Table 5, at the corresponding TRIX boundary between Good and Mediocre Trophic Status (TRIX = 5; Giovanardi et al, 2018), which matches the transition from mesotrophic to eutrophic conditions in the coastal ecosystem.

This boundary was used for Type II A Adriatic Sea giving the values of 0.48 µmol/L. For Type I, the value of TRIX for deriving the G/M boundary was increased to 5.25, in order to take into account the nutrient loads originating from natural sources carried by the Po River into the Adriatic Sea, presumably in not negligible amounts. In this way, the G/M boundary for TP was set at 0.55 µmol/L for Type I. In the same manner all boundaries` values for Types I and II A Adriatic were calculated (Tables 6 and 7).

The identified P/B boundaries refer to "virtual" conditions, since it was not possible to detect real situations related to ecological class “Bad” in any of the datasets analysed in this work. TP concentrations characterizing “Bad” ecological class have been extrapolated from the functional relationships extended to the area of the diagrams not actually covered by observations. It is impossible to predict how coastal systems would behave with such high concentrations of phosphorus, especially since annual averages need to be determined. Therefore, this class is considered as indicative, but not strictly necessary for proper ecological classification of the BQE phytoplankton based on TP concentration.

Table 6. Reference conditions and boundaries of ecological quality classes for BQE phytoplankton expressed by different parameters for Type I coastal waters.

Boundaries	TRIX	Chl-a annual *G_Mean*	TP annual *G_Mean*
		µg/L	µmol/L
Reference Conditions	-	1.40	0.19
H/G	4.25	2.0	0.26
G/M	5.25	5.0	0.55
M/P	6.25	12.6	1.15
P/B	7	25.0	2.00

Table 7. Reference conditions and boundaries of ecological quality classes for BQE phytoplankton expressed by different parameters for Type II A Adriatic coastal waters.

Boundaries	TRIX	Chl-a annual *G_Mean*	TP annual *G_Mean*
		µg/L	µmol/L
Reference Conditions	-	0.33	0,16
H/G	4	0.64	0.26
G/M	5	1.5	0.48
M/P	6	3.5	0.91
P/B	7	8.2	1.71

Type III W Adriatic

Following the same approach used for Type I and II A waters, overall G_means of nutrients` concentrations were related to the dilution factor for Type III W. No correlation was found for DIN

(R2=0.05; P=0.303), while for the TP the relationship was even inverse to the one expected (Giovanardi et al, 2018). Additionally, overall values of G_mean of chlorophyll *a* range from around 0.1 to around 0.4 µg/L. Since the ecological classification scheme consists of 5 ecological quality classes, the discrimination limit between two contiguous chlorophyll *a* annual G_mean values would not be suitable for proper and safe classification (Giovanardi et al, 2018). For that reason, a single threshold value is therefore proposed for Type III W coastal waters that is the H/G value for Type IIA Adriatic of 0,26 µmol/L.

Other suggested methodologies for boundaries setting

The Best Practice Guide (BPG, Nutrient boundaries definition toolkit, JRC)

The document "*Best practice for establishing nutrient concentrations to support good ecological status*" is developed by the Joint Research Centre (JRC), the European Commission's science and knowledge service (Phillips et al, 2018). The purpose of the document is to help EU MSs achieve good ecological status (GES) in surface waters. It complements the Common Implementation Strategy (CIS) Guidance document on eutrophication assessment in the context of European water policies (EC, 2009) by providing advice on how to link nutrient concentrations in surface waters to specific policy objectives. It can be used to check existing boundaries` values or to develop new ones. The guidance is supported by a toolkit in the form of an Excel workbook and a series of scripts which can be run using R, an open-source language widely used for statistical analysis and graphical presentation (R Development Core Team, 2016[67]). The toolkit provides the full R code, together with a series of examples which can be used to explore the methods.

This toolkit includes different statistical approaches to derive nutrients` boundaries, as elaborated here-below.

Univariate linear regression: Assuming a linear relationship between the ecological quality ratio (EQR) and nutrients, three regression types are implemented: two ordinary least squares OLS linear regressions between EQR and log nutrients concentration, where each variable is alternatively treated like the independent variable (because none of our two variables in practice can be considered to be free of error); and a third, type II regression, the ranged major axis (RMA) regression. The predicted range of nutrients` threshold values are then determined from the range of results obtained from these regressions' parameters.

Logistic regression: This approach treats ecological status as a categorical variable where a logistic model is fitted between categorical data using a binary response, "biology moderate or worse" = 1 or "biology good or better" = 0 and log of nutrient. Nutrient concentrations are determined where the probability of being moderate or worse was 0.5. In the case that additional pressures, other than nutrients, are suspected, a nutrient concentration value was determined at a probability of 0.75 instead of 0.5.

Categorical methods: Nutrient concentrations associated with a particular ecological status class could also be expressed as a distribution from which an upper quantile might be chosen to indicate a nutrient concentration above which good status was very unlikely to be achieved, or a lower quantile below which good status was very likely to be achieved (average of upper and lower quartiles of adjacent classes), so long as nutrients are the main driver of status. The average of the median of adjacent classes and the upper 75th percentile distribution are two additional categorical approaches tested.

Minimisation of mismatch of classification: Estimates the nutrient threshold value that minimizes the mismatch between status (good or better and moderate or worse) for the ecological and the supporting element.

---

[67] R Development Core Team (2006). R: A language and environment for statistical computing. R Foundation for Statistical Computing, Vienna, Austria.

Linear quantile regression: Useful alternative when the nutrient-biology interactions are confounded by other stressors, or environmental factors, leading to wedge-shape, or inverted- wedge, type of distributions. In such cases, the quantile regression allows different rates of change in the response variable to be predicted along the upper (in the presence of stressors) or lower (in the presence of mitigating environmental factors) quantiles of the distribution of the data (Cade and Noon, 2003[68]). Detailed information about the methods included in the toolkit is provided in the Guidance (Phillips et al., 2018).

Experience of Spain in establishment of nutrient boundary values for coastal waters of Catalonia

The FAN (Phosphate-Ammonium-Nitrite) and FLU (FLUviality) indices method assesses the physicochemical state of coastal waters and allows nutrient boundary values to support GES to be established. This method is based on a distinctly different process to establish these values than those described in this document. Rather than using nutrient and BQE data simultaneously, it assesses the physicochemical state of coastal waters and then it relates this to the BQE. Nutrients` boundary values are then established from this relationship. This approach considers several dissolved inorganic nutrients concentrations and their stoichiometry at the same time rather than focusing on a single nutrient, as is the case when applying the toolkit.

The FAN and FLU indices method was developed using the physicochemical database of the Catalan Coastal Water Monitoring Programme. The data are representative of the north-west Mediterranean and comprise 20,102 records from 268 sampling stations collected between 1994 and 2014. A factorial analysis performed with this database revealed that the main pressures impacting coastal waters are *continental influences* (CI), which are related to gradients of dissolved inorganic nutrients, and freshwater content (inverse of salinity). An assessment of the physicochemical state of coastal waters based on the CI yielded results nearly equivalent (correlation of 0.93) to those obtained with the Trophic Index (TRIX) of Vollenweider et al. (1998). A further rotation applied to the factorial analysis revealed that CI is divided into two distinct gradients: levels of dissolved inorganic ammonium, phosphate, and nitrite define a gradient of urban influences while levels of dissolved inorganic silicate, and nitrate as well as the freshwater content, represent a gradient of freshwater influences or fluviality. The former is considered to reflect urban influences and the latter natural continental pressures on coastal waters (although freshwater influences are partly related to nitrate enrichment from agricultural sources).

These gradients of urban and freshwater influences were the basis for development of the FAN and FLU indices. The FAN index is scaled into five categories of water quality (high, good, moderate, poor and bad) and the FLU index into five categories of fluviality (very low, low, medium, high, and very high). The combined results provide a final assessment of the CI reaching coastal waters (urban, fluvial, mixed, or none) and, therefore, an assessment of their physicochemical state. The indices can be applied using data from inshore (0-200 m from the shore) or offshore (> 200 m from the shore) waters or both. The procedure, equations, and boundaries to apply the FAN and FLU indices together with detailed information on the method are available in Flo (2017[69]).

Elaboration of the assessment criteria i.e. reference conditions and boundary values for DIN and TP

Although setting of the assessment criteria for nutrients, transparency and oxygen was recognized as a minimum to address needs identified in 2017 Mediterranean Quality Status Report, data availability

[68] Cade, B.S. and Noon, B.R. (2003). A gentle introduction to quantile regression for ecologists. Frontiers in Ecology and the Environment 1: 412-420.
[69] Flo, E. (2017). Opening the black box of coastal inshore waters in the NW Mediterranean Sea: environmental quality tools and assessment. PhD. 372 pages.

indicates that setting of RCs and boundary values is possible for DIN and TP only, and even for them in several sub-areas, but not at regional Mediterranean level.

To that effect the following datasets need to be provided as a minimum requirement: three continuous year of monitoring with a minimum monthly frequency for Water Type I; bimonthly frequency for Water Type II although preferable monthly; and seasonal frequency for Water Type III.

Further to analysis of monitoring data availability, the most suitable methods for setting the assessment criteria are recognized for each sub-area (Table 8). As explained above, data availability survey also indicates that data with unrestricted use from EMODnet may be used to supplement data sets available in IMAP Pilot Info System/MEDPOL.

Table 8. The Mediterranean sub-regions/subareas[70], where setting of the assessment criteria for DIN and TP is found possible in line with availability of monitoring data, along with relevant methods for setting of the boundary values.

Sub-regions	Sub-division (e.g. subareas/seas)	Availability of data (IMAP database + EMODNet)	Boundary setting method considered
Western Mediterranean Sea (WMS)	Alboran Sea (ALBS)	CPs contribution needed; data availability is restricted only to the northern part (Spain)	FAN/FLU, BPG toolkit
	North Western Mediterranean Sea (NWMS)	Probably sufficient; CPs should further improve data availability	Methodology for Adriatic sub-region, BPG toolkit
	Tyrrhenian Sea (TYRS)		Methodology for Adriatic sub-region
	Western Mediterranean Islands and Archipelago (WMIA)	Insufficient data	-
Adriatic Sea (ADR)	North Adriatic (NADR) Middle Adriatic (MADR) South Adriatic (SADR)	Probably sufficient data available; Adriatic Sea needs to be considered as a whole; CPs should further improve data availabilit;	Methodology for Adriatic sub-region
Central Mediterranean (CEN)	Central Mediterranean (CEN) Ionian Sea (IONS)	Insufficient data	-
Aegean and Levantine Seas (AEL)	Aegean Sea (AEGS) Levantine (LEVS)	Probably sufficient data available for the northern part, only; CPs should improve data availability	BPG Toolkit, Methodology for Adriatic sub-region

The Online Working Group (OWG) on eutrophication needs to support present work through data collection, elaboration and application of the methods for setting boundary values including relevant statistical approaches.

The setting of RCs and boundary values for DIN and TP is the essential step in supporting application of present assessment criteria for chlorophyll *a,* as established by Decisions IG.22/7. The G/M threshold for DIN and TP is the most important boundary which delimits the need for taking measures

[70] (UNEP(DEPI)/MED WG.427/Inf.3)

in case of GES failure. The development of the boundary values for the full scale of the relationship between pressures and effects will also allow monitoring of mitigation measures.

Within the scope of present IMAP implementation, development of the assessment criteria for transparency and dissolved oxygen is premature mainly due to the fact that elements of the measurements presently unrelated to primary production (Fleming-Lehtinen, 2016[71]) cannot be clearly identified. That is particularly true for shallow and coastal areas that are the most of our interest.

This proposal for setting the assessment criteria for DIN and TP within implementation of IMAP CI 13 corresponds well with the most recent findings related to EU WFD and MSFD implementation (Salas Herrero et al, 2020[72]). These findings refer to comparison between the information reported by EU MSs to WISE on the standards for general physico-chemical quality elements, including nutrients and the information on methodologies used to assess eutrophication in coastal waters in accordance with MSFD, with the methodological standards agreed and used for the assessment of the elements for eutrophication criteria (i.e. nutrient conditions, transparency, and dissolved oxygen) at regional sea level.

Programme of Work for Biennium 2022-2023

Rationale for the Proposed Programme of Work 2022-2023

1. Decision IG.24/14 "Programme of Work and Budget 2020-2021", adopted by the 21st Meeting of the Contracting Parties (COP21) in December 2019, in Naples, Italy, mandates the Secretariat to prepare, in consultation with the Bureau, for consideration and approval by COP22, a result-based Programme of Work (PoW) and Budget for 2022-2023, explaining the key principles and assumptions on which it is based and taking into account the progress achieved during the implementation of the 2020-2021 Programme of Work, and in full alignment with the MTS. The new MTS is built around 7 Programmes. MED POL will contribute to Programme 1, 5,6 and 7 as explained below.

Thematic Programme 1: Towards a Pollution and Litter Free Mediterranean Sea and Coast Embracing Circular Economy

2. More specifically, the proposed 2022-2023 PoW envisages:
   a) Boosting the implementation of the Regional Plan on Marine Litter management through national, subregional and regional actions, with a particular focus on plastics;
   b) Implementation of Regional Plans addressing priority pollutants and sectors, including through development of regional standards and guidance;
   c) Developing new Regional Plans for the management of pollutants' releases from Agriculture, Aquaculture and Storm Water;
   d) Updating guidelines and strengthening national capacities for the implementation of the Dumping Protocol;
   e) Undertaking pilot actions to prevent, eliminate and dispose in an environmentally sound manner obsolete chemicals;
   f) Strengthening the capacity of individual coastal states to respond efficiently to marine pollution incidents; improving pollution event follow-up and enhancing the level of enforcement and the prosecution of discharge offenders;
   g) Supporting public and private actors in preventing marine litter and toxic chemicals, addressing the circular economy approach;
   h) Developing and implementing the One Health approach in the Mediterranean in relation to pollution links with human health;
   i) Supporting the creation and development of circular economy businesses in key sectors of activity which are main sources of pollution;

Foundational Programme 5: Governance

3. With regards to MED POL contribution to this Programme the following activities are proposed:
   a) Supporting national efforts for further progressing on the ratification of the Pollution related Protocols to the Barcelona Convention;
   b) Reinforcing Contracting Parties' capacities on enforcement of, compliance with, and reporting on legally binding provisions of the MAP Barcelona Convention framework; with a particular focus on Pollution related Protocols;
   c) Contribute to the evaluation of the implementation of the Ecosystem Approach Roadmap and IMAP, and elaborating a new/updated Roadmap as appropriate;
   d) Contribute to the strengthening SPI networks with a focus on IMAP;
   e) Strengthening partnerships with MEA of relevance, Global and regional networks in the scope of the application of the Pollution related protocols of the Barcelona Convention as well as of Regional Plans adopted in the framework of Article 15 of the PBS Protocol;

f) Expand and strengthen the Marine Litter Regional Platform in close collaboration with European Regional Seas and GPML of the UNEP/GPA

g) Promoting gender mainstreaming into MED POL operations and activities.

Enabling Programme 6: Together towards a Shared Knowledge and Foresight of the Mediterranean Sea and Coast

4. With regards to MED POL contribution to this Programme the following activities are proposed:

a) Delivering a data-based 2023 Mediterranean Quality Status Report in line with its implementation Roadmap adopted by COP 21 (Decision IG. 24/4); for EO 5,9 and 10 including GES integrated assessment aspects

b) Further developing IMAP for the Pollution and Litter clusters (developing or upgrading monitoring and assessment criteria for IMAP common indicators (CIs), establishing scales of assessment, and defining integration and aggregation rules, Data Standards (DSs) and Data Dictionaries (DDs) etc.);

c) Implementing IMAP at national and as appropriate sub-regional level; deliver quality assured data, organize proficiency exercises to enhance national capacities in delivering and reporting quality assured data;

d) Completing and maintaining the IMAP Info System for all IMAP Common Indicators and ensuring full implementation of the InfoMAP Spatial Data Infrastructure (InfoMAPNode), including coordination with relevant Regional Organizations Infosystems and databases; for the Pollution and Litter Cluster

Enabling Programme 7: For Informed and Consistent Advocacy, Awareness, Education and Communication

5. With regards to MED POL contribution to this Programme the following activities are proposed:

a) Producing and disseminating communication material, i.e. press releases, news items, articles, videos, brochures, web series, social media products etc. and organizing outreach events; based on the deliverables of MED POL work.

b) MTS Programme 1. Towards a pollution and litter free Mediterranean Sea and Coast embracing circular economy

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
Outcome 1.1. Strategies and Action plan addressing marine litter and plastics developed and implemented through comprehensive, coherent and collaborative approaches						
1.1.1. Undertake national, subregional, regional actions to boost the implementation of the Marine Litter Regional Plan in the Mediterranean (in-house expertise, consultancy, regional/ sub-regional meetings, regional platform, pilots and national capacity building)	**a)** Pilot actions implemented in at least 14 sites in 6 countries on fishing for litter, adopt a beach, waste management at ports measures through the application of common MAP Regional Adopted Guidelines.	MED POL	SCP/RAC, REMPEC	EU funded Water and Environment Support (WES) Project, EU funded EPPA, GIZ,	12.4; 12.5; 14.1	MTF and EU funded ML MED II
	b) Best practices shared at national, regional/subregional level, including with local authorities, on the effective implementation of Marine Litter Regional Plan, addressing improving separate waste collection/ transportation systems, combating marine and coastal pollution from open dumpsites, cost-benefit dimension of measures implementation and promoting zero waste initiative.			UNEP GPA, OSPAR, Black Sea Commission, GPML		
	c) Membership to the Regional Platform for Marine Litter in the Mediterranean expanded.	CU, MED POL	SCP/RAC, REMPEC, SPA/RAC	ML MED Regional Platform (over 20 regional and global actors), Plastic Partnership (Basel Convention), GIZ,	12.4; 12.5; 14.1	MTF and EU ML MED Project
	d) Joint Work Plan of the members of the Regional Platform agreed annually and implemented; at least two joint activities implemented with Partners.	MED POL				

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
1.1.1. Undertake national, subregional, regional actions to boost the implementation of the Marine Litter Regional Plan in the Mediterranean (in-house expertise, consultancy, regional/ sub-regional meetings, regional platform, pilots and national capacity building)				WES, EPPA		
	e) Technical support provided to CPs, which so request, to implement the IMO Action Plan to address marine plastic litter from ships and the related provisions of the Regional Plan on Marine Litter Management in the Mediterranean, where appropriate. **f)** Relevant activities of the IMO-FAO-Norway GloLitter Partnerships Project facilitated in the Mediterranean, as appropriate. **g)** Synergies between the amended Regional Plan on Marine Litter Management in the Mediterranean and the IMO Action Plan/Strategy to address marine plastic litter from ships, as well as other relevant plans or initiatives, maintained and strengthened.	REMPEC, CU	MED POL	IMO, FAO, GFCM, EBRD	12.4; 12.5; 14.1	External resources
1.1.3. Implement and scale up a robust policy framework to reduce and prevent plastic use (in-house expertise, consultancy, cooperation agreements, regional meetings/webinars)	**a)** National cooperation agreements between public and private stakeholders to prevent plastic pollution and reduce plastic waste in 2 countries; guidance provided.	SCP/RAC	MED POL, CU	TBD	12.1; 12.4; 12.5; 14.1	MTF
	b) Legal and technical support provided to public authorities to strengthen policy framework to reduce plastic use, addressing in particular Single Use Plastic Products.					DG ENV (Marine Litter Med II) + DG NEAR (WES) + MTF
	c) Sharing existing solutions and good practices to prevent plastic use and pollution by applying eco-innovation, life cycle thinking (including eco-design). **d)** 3 webinars on solutions to prevent plastic pollution.					MTF

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
	e) 20 Food services located in coastal areas supported to implement measures to reduce food and beverage packaging ending-up as Marine Litter.					External resources expected from IMELS
1.1.4. Enhance stakeholders 'capacity, in particular public authorities, to prevent plastic and microplastic pollution (in house expertise, consultancy, national and regional trainings)	**a)** 1 regional training on microplastics organized. **b)** 3 national trainings on EPR/SUPs/solutions to prevent ML organized.	SCP/RAC	MEDPOL, PAP/RAC	TBD	12.4 ;12.5; 12.a; 14.1	DG NEAR (WES) + DG ENV (Marine Litter Med II) + MTF
	c) 1 training programme on ML prevention targeting coastal municipalities organized and good practices shared.					MTF
Outcome 1.2. A holistic and efficient response to land and sea-based pollution, [as a part of overall Ecosystem Approach for Mediterranean policy] (chemicals, contaminants, eutrophication, noise, oil and emerging pollution) for a sustainable Mediterranean coastal and marine ecosystem is implemented						
1.2.1. Develop new regulatory measures in line with article 15 of the LBS Protocol for priority sectors as provided for in the Decision IG.24/10 (in house expertise, consultancy, consultation, regional meetings)	**a)** Regional Plan on Agriculture and Aquaculture.	MED POL, CU	Plan Bleu, SCP/RAC	(WES) Project	6.3; 12.4; 14.1	MTF
	b) Regional Plan on Storm Water management.					
	c) State of Play Report on pre-treatment of industrial effluents standards for industries discharging into urban wastewater collection systems prepared.					

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
1.2.2. Take national and regional actions including enabling investments, to implement Regional Plans on WasteWater and Sludge Management (in-house expertise, consultancy, national trainings/capacity building activities, regional meeting)	**a)** Preparatory studies on investment potential for wastewater treatment/collection network projects addressing NAP hotspots in three countries (Egypt and Lebanon) or completed (Tunisia).	CU, MED POL	SCP/RAC	GEF, European Investment Bank, UNEP, GPA	5.c; 6.5; 6.6; 6.a; 12.4; 13.1; 14.1	GEF
	b) Capacity building programs for national water and sanitation agencies/companies initiated (Egypt and Lebanon) or completed (Tunisia)					
	c) Action plans for gender mainstreaming in the wastewater sector initiated (Egypt, Lebanon and Tunisia).					
	d) Regional standards for urban wastewater treatment and sewage sludge management developed including wastewater reuse, and energy efficiency and monitoring protocol for microplastics in wastewater. **e)** Best practices shared.	MED POL		GEF, European Investment Bank, UNEP, GPA		External (MedProgramme)
1.2.3. Promote sustainable Desalination Sector in the Mediterranean (in-house expertise, consultancy, publication, regional meeting)	**a)** State of play of Desalination in the Mediterranean made available through maps or publication. **b)** Recommendations elaborated in a decision support tool to assist sustainable investment decision-making & dissemination of the tool through participation in events.	Plan Bleu	MED POL	MedProgramme, AFD, UNIDO	6.3; 6.a; 12.4; 14.1	MTF, External funds

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
	c) Regional standards on desalination technologies. **d)** Best practices to minimize environmental impact of desalination compiled and shared.	MED POL	Plan Bleu			
1.2.4. Enhance the implementation of MED POL reporting tools developed to assess pollution loads from land based sources and activities (in-house expertise, consultancy, regional meeting)	**a)** PRTR/NBB Guidelines implemented and data reported including diffuse sources. **b)** Pollution trends assessed at national and sub-regional/regional levels.	MED POL	CU	EEA, UNECE, OECD, EPPA	9.4; 12.4; 14.1	MTF
	c) Best practices shared at regional level to exchange knowledge on reporting (PRTR, NBB , NAP/H2020 indicators).					
1.2.5. Undertake national and regional action to enhance the implementation of the Dumping Protocol (in-house expertise, consultancy, regional meeting)	**a)** Best practices shared to support the implementation of Dumping Protocol Guidelines adopted by COP 21 (Artificial reefs).	MED POL	CU	LC/LP, IMO, IMPEL	12.4; 14.1	MTF
	b) Guidelines on dumping of uncontaminated inert materials updated in synergy with the IMO London Protocol.					
1.2.6. Undertake pilot actions to prevent, eliminate and dispose in a environmentally sound	**c)** Training activities to engage the private sectors in using alternatives to toxic chemicals organized in 3 counties.		MEDPOL			GEF (MedProgramme)

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
manner obsolete chemicals. (in-house expertise, consultancy, national trainings/capacity building activities, field visits, regional meeting)	**d)** 500 tons of PCBs in Algeria and Lebanon collected and disposed; PCBs inventory in Algeria, Morocco, Tunisia, Albania, Bosnia and Herzegovina, and Montenegro) updated.	MED POL	CU, SCP/RAC	MedProgramme, Stockholm Convention, Minamata Convention, UNEP Chemicals		GEF (MedProgramme)
	e) EMP for mercury stocks in Algeria, B&H, Morocco and Tunisia; 50 tons of Mercury in Algeria, B&H, Morocco and Tunisia collected and disposed.					
	f) Best practices for management of obsolete/in stock chemicals (focus on PCBs, POPs, mercury), including on compliance and enforcement shared. **g)** Capacity building provided to relevant national authorities with a focus on inspectorate bodies.					
1.2.7. Strengthen and implement national frameworks to regulate/ ban the use of POPS/toxic chemicals (in-house expertise, consultancy)	**a)** Support provided to 3 countries to regulate/ban the use of POPs/toxic chemicals. **b)** Mechanisms developed to accompany companies in phasing out certain chemicals.	SCP/RAC	MED POL	MedProgramme	12.1; 12.a; 14.1	GEF (MedProgramme)

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
1.2.8. Increase access to information on chemicals in products (in-house expertise, consultancy, national trainings, public webinars, awareness raising)	**a)** Facility, hub, awareness campaigns to increase knowledge on chemicals in products in cooperation with companies and citizens associations. **b)** Master module on toxic chemicals in plastics prepared and delivered in 3 countries.	SCP/RAC	MEDPOL	SwitchMED II, UNIDO, MehMEd Network, University of Girona	12.8	BRS Secretariat (only for Master module)+ MTF
	c) Interactive web platform to raise awareness on chemicals in plastic products prepared.					MTF
	d) 3 public webinars on strategies to prevent chemicals in products organized.					BRS Secretariat (only for 2 Webinars)+ MTF
Outcome 1.3. Systemic approaches for Circular Economy as well as Sustainable Consumption and Production incorporated into key sectors of activity which are main sources of pollution						
1.3.1. Promote SCP/Circular economy approaches in key sectors of LBS Protocol (in-house expertise, consultancy)	**a)** Circular economy approach for biowaste implemented in one country.	SCP/RAC	MED POL	SwitcMed	12.1; 12.a	MTF Funding required
Outcome 1.4. One Health approach developed and implemented, linking human and ecosystems health with pollution reduction and prevention, taking into account lessons learnt from the COVID-19 pandemic						

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
1.4.1. Develop and implement a one-health approach for the Mediterranean, in partnership with WHO and FAO (2022/2023) (in-house expertise, consultancy, regional conference)	**a)** Comparative assessment of impact of environmental factors on health in the Mediterranean region conducted through literature review. **b)** A Med-wide conference on One-Health approach for the Mediterranean; Conference report published and disseminated.	Plan Bleu	All MAP Components	WHO, FAO, UNEP, UNESCO, One Health High-Level Expert Council	3.9; 14.1; 14.2	MTF
1.4.2. Implement the agreed Med SOx ECA Road Map (Decision IG.24/8), and explore the possible designation of the Mediterranean Sea, as a whole, as an Emission Control Area for nitrogen oxides (in-house expertise, consultancy, national workshops, regional meeting)	**a)** Technical support and capacity building provided to CPs, which so request, to ratify and effectively implement MARPOL Annex VI.	REMPEC	CU, MED POL, PB/RAC	IMO		MTF
	b) Joint and coordinated proposal for the designation of the proposed Med SOx ECA submitted to the IMO, and discussions at MEPC facilitated, as appropriate. **c)** Mediterranean Action Plan (MAP) nitrogen oxides (NOx) Emission Control Area (ECA)(s) Technical Committee of Experts established			IMO	3.9; 12.4; 14.1	MTF
	d) Terms of Reference for a specific Technical and Feasibility Study to assess the relevant existing studies and gather further knowledge on the possible designation of the Mediterranean Sea, as a whole, as an Emission Control Area for nitrogen oxides, developed and validated by the NOx ECA(s) Technical Committee of Experts.	REMPEC	CU, MED POL, PB/RAC	IMO, HELCOM, OSPAR, Bonn Agreement		MTF

d) MTS Foundational Programme 5: Governance

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
Outcome 5.1. Effective Implementation and Enforcement by the Contracting Parties of the Barcelona Convention, its Protocols, MAP Policies, including Ecosystem Approach related COP decisions, the MSSD and Programmes of Measures achieved at regional and national levels						
5.1.1. Strengthen Contracting Parties action to comply with legally binding obligations under Barcelona Convention and its Protocols (in-house expertise, consultancy, technical national assistance, regional meeting)	**d)** Contracting Parties develop national policies, legislation and mechanisms for the implementation and enforcement of the BC Protocols. **e)** Technical assistance to CPs to develop national policies, regulatory frameworks and which are consistent with the BC and its Protocols is provided.	CU	MAP Components, (MEDPOL, PAP/RAC SPA RAC, REMPEC)	MEAs, UNEP	All SDG 14 Targets especially 14.2 and14.c; 16.3; 17.14	Both
Outcome 5.2. Systemic strengthening and effective functioning and delivery of MAP decision-making and advisory bodies ensured, and efficiency enhanced with new digital approaches						
5.2.1. Deliver successfully COP 23 of MAP Barcelona Convention (in-house expertise, Host Country Agreement, conference services, venue, side events, travel arrangements)	**a)** COP 23 Declaration, Decisions including the PoW 2024-2025 reviewed and adopted, recommendations of the Compliance Committee and the MCSD reviewed. **b)** Progress achieved during the biennium 2022-2023 reviewed and acknowledged.	CU	MED POL, RACs	Host country, CPs, MAP Partners	All SDG 14 taregst especially 14.c; 16.3; 17.14; to a lesser extent SDGs 6, 12, 13	Both

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
	c) Status of implementation of the Convention and its Protocols reviewed. **d)** MAP visibility and outreach enhanced.					
5.2.4. Organize Compliance Committee Meetings (in-house expertise, conference services, travel arrangements)	**a)** 2 Compliance Committee Meetings successfully convened; Non-compliance situations addressed and brought to the attention of COP 23.	CU, Compliance Commitee	MEDPOL, RACS	Compliance Committes under relevant MEA	All SDG 14 targets especially 14.c; 16.3; 17.14; to a lesser extent SDGs 6, 12, 13	MTF
	b) Interactions and possible joint sessions with Compliance Committees of other MEAs held.					
	c) Compliance Procedures and Mechanisms further developed with additional elements to maximise their effective use and impacts.					
Outcome 5.3. Policy coherence and complementarity ensured among relevant work at global, regional and national levels and among MAP-Barcelona Convention system's policy and regulatory instruments						
5.3.3. Strengthen cooperation for joint reporting under the BC and its Protocols (in-house expertise, national trainings, twinning's)	**a)** Mechanisms for promoting mutual supportiveness with other relevant international instruments when it comes to reporting developed.	CU	RACs, MEDPOL	MEAs	All SDG 14 taregst especially 14.c; 16.3; 17.14; to a lesser extent SDGs 6, 12, 13	Both
	b) Support for reporting provided at national level (e.g. e-reporting modules, twinning approach).					

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
Outcome 5.4. Enhanced partnerships and multi-stakeholder engagement, including with the private sector and science policy interface						
5.4.1. Promote dialogue and enhanced engagement of global and regional organizations and partners (in-house expertise, partnerships, bilateral cooperation, private sector engagement)	**a)** Leading role of MAP further defined and strengthened in existing and new areas. **b)** New areas of cooperation identified and added to existing bilateral cooperation agendas: Focus GFCM, UfM, Biodiversity related organizations, Marine Litter. **c)** Cooperation with new partner institutions, including form private sector, initiated.	CU	RACs, MEDPOL	International and regional organizations, private sector/donors, UNEP, MEAs, CPs	17,17	Both
5.4.2. Strengthen participation and contribution of civil society and private sector to the work of MAP BC system (in-house expertise, support attendance in MAP meetings, round tables)	**a)** MAP Policy on Partnerships updated including an Engagement mechanism/strategy for Civil Society Organisations. **b)** New MAP Partners added and existing MAP Partners renewed; Enhanced engagement of MAP Partners in policy development and implementation. **c)** Annual round table discussions held (back-to-back with other meetings).	CU	RACs, MEDPOL	MAP Partners, NGOs, CPs	17,17	Both

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
5.4.3. Strengthen SPI networks and enhnace partnership with scientific instiutions to support MAP Barcelona Convention system (in-house expertise, consultancy, pilot action(s), national thematic events/workshops)	**b)** Partnership Agreement signed with scientific Institutions to support integrated assessment of GES. **c)** SPI platform set up to support IMAP implementation at national and regional levels.	CU	All MAP Components, IMAP Task Force	Scientifc institutions; UNESCO; IOC; CNR		
	d) National thematic IMAP SPI networks/hubs established in two countries.	Plan Bleu, CU	All MAP Components, IMAP Task Force			
	e) Joint Work Plan 2022-2027 between EEA and UNEP/MAP implemented (main areas of cooperation: Building strengthened knowledge base; Responding to political priorities; Supporting digital transformation; Ensuring coordinated networking, communication and stakeholder interaction).	CU	INFO/RAC, MED POL, Plan Bleu, PAP/RAC	EEA, EIONET, ETC, H2020, DG NEAR		Both
Outcome 5.5. Coordinated approaches implemented to strengthen public institution capacities for the implementation of the Barcelona Convention and its Protocols						
5.5.1. Strengthening national governance frameworks for the BC and its Protocols (in-house expertise, partnerships)	**a)** Short courses designed and organized linked to the implementation and enforcement of the BC and its Protocols in universities and other academic institutions.	CU	MEDPOL, RACs	MEAS, UNEP, Academic institutions, InforMea	All SDG 14 targets especially 14.c; 16.3; 17.14	Both

e) **MTS Enabling Programme 6: Together towards a shared knowledge and foresight of the Mediterranean Sea and coast**

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
Outcome 6.1. Inclusive and participatory foresight activities conducted at regional and national and local levels, with associated capacity-building						
6.1.2. Prepare the Transboundary diagnostic analysis for the Mediterranean Sea (in-house expertise, consultancy)	**a)** Methodology of the Transboundary diagnostic analysis elaborated; priority transboundary problems identified for the Mediterranean Sea; socio-economic characteristics assessed.	CU, MEDPOL	CU, IMAP Task Force (including SPA/RAC, Plan Bleu, INFO/RAC)	National IMAP competent laboratories / authorities; relevant national and international scientific institutions; EU MSFD technical bodies;	14.a	GEF MED Programme: Child Project 1.1.
Outcome 6.2. Science-based IMAP, foresight and other assessments and assessment tools for strengthened science-policy interface and decision making						
6.2.1. Strengthen the implementation of national IMAP-based monitoring programmes for all clusters and deliver quality assured data (in-house expertise, consultancy, IMAP TF, national assistance and trainings)	**d)** Technical and financial support provided to support pollution and litter cluster of IMAP to at least 7 countries to ensure delivery of quality assured data, as well as their reporting using the IMAP Info System.	MEDPOL				

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
6.2.2. Upgrade the assessment component of IMAP including possible integrated assessment for all IMAP clusters: Focus Assessment criteria and thresholds (CI 1, 2, 6, 13, 14, 16, 17, 21, 22, 23) (in-house expertise, consultancy, IMAP TF, CORMONs)	**g)** Updated/new scales of monitoring and assessment proposed for mandatory Common Indicators as applicable (EO 5,9, 10). **h)** GIS atlas prepared for scales of monitoring and scales of assessment to be integrated into IMAP Info System. **i)** IMAP methodology on integrated assessments adjusted and further developed. **j)** Proposals to upgrade IMAP discussed by CORMONs Pollution and Litter and ECAP CG meeting. **k)** Further progress on assessment criteria and thresholds for IMAP Common Indicators 13, 14, 17, 18, 22 and 23, if possible also at sub-regional level, based on data availability.	MED POL				
6.2.4. Deliver 2023 MED Quality Status Report (QSR)(in house expertise, thematic assessments, consultations with partners, GIS maps, IMAP TF, CORMONs)	**b)** Thematic assessments for Ecological Objectives 5, 9 and 10 contributing to 2023 MED QSR whilst progressing towards integration among these 3 EOs and as appropriate with other Ecological Objectives 1, 7 and 8 of IMAP Biodiversity, Coast and Hydrography Cluster, as appropriate and feasible; CORMON Meeting held annually.	MED POL, CORMON Pollution and Litter				

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
	e) Elaboration and spatial data analysis of monitoring data aggregated by MAP components for the purposes of 2023 MED QSR.	INFO/RAC	CU, MAP Components	UNEP-GRID, UNIGE	All SDG 14 targets especially 14.a 12.8	MTF
Outcome 6.3. [IMAP implementation and] Environment and Development Observation provide updated and quality assured data in support of decision-making by Contracting Parties and assessment of GES.						
6.3.1. Strengthen national capacities to apply harmonized and standardized monitoring and assessment practices related to pollution and marine litter in line with IMAP (in-house expertise, consultancy, field survey, national laboratories, training, IMAP TF)	**a)** National MED POL/ IMAP laboratories supported to apply good laboratory practices for monitoring of contaminants in biota and sediment, as well as for biomarkers if feasible, through organization of the proficiency tests (PT) and related Training Courses. **b)** Proposal prepared for inter-calibration proficiency testing and training courses for eutrophication (nutrients and chlorophyll-a) in seawater.	MEDPOL	CU, IMAP Task Force	IAEA;National IMAP competent authorities; Scientific institutions; bodies EU MSFD	14.1; 14.a	Both
6.3.4. Ensure effective operation of the NBB reporting system (in-house expertise, national technical assistance and trainings)	**d)** Relationship with the PRTR and EU Registry component implemented, and assessment functions strengthened at regional, subregional, national and river basin scale.	MED POL		EEA		MTF

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
6.3.6. Complete and maintain IMAP Info System with all IMAP Common Indicators fully implemented for the CPs to upload their monitoring data	**b)** Data Standards (DSs) and Data Dictionaries (DDs) developed for IMAP Common Indicators (all the remaining ones: part of them with the support of the EcAp MED III Project).	CU	MED POL, SPA/RAC, PAP/RAC			Both
	c) Quality control on data formats and data coherence upgraded and developed for IMAP Cis (all the remaining: part of them with the support of the EcAp MED III Project).		MED POL, SPA/RAC, PAP/RAC			Both
	d) Dedicated assistance and support trainings to CPs to organize, upload, validate and release monitoring data in 2022 and 2023. Creating and sharing tutorials on the IMAP site to help CPs in workflow processes.		MED POL, SPA/RAC, PAP/RAC			Both
6.3.12. Develop monitoring protocols and guidelines (in-house expertise, consultancy)	**a)** Monitoring Guidance/Protocols prepared for IMAP CI23 (seafloor macro-litter, beach macro-litter; as well as for floating macro-litter, beach micro-litter, and seafloor micro-litter), as well as for Candidate Indicator 24, as feasible due to availability of relevant scientific inputs.	MED POL			14.1	
	b) Guidelines for monitoring microplastics deriving from WWTP and riverine inputs of marine litter are prepared.	MED POL	SCP/RAC			ML MED II

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
6.3.13. Expand and improve the monitoring and forecasting capacities in the marine environment through integrating networks of observing and forecasting systems (oceanographic observatories) across the Mediterranean Sea(in-house expertise, consultancy, trainings and working meetings)	**a)** Priority needs and actions agreed to strengthen reliable and cost-effective monitoring and GES assessment related to IMAP Pollution Cluster, including use of best available knowledge and technologies within science-policy interface, thereby also contributing to the Implementation Plan of UN Decade on Ocean Science.	MEDPOL	CU, SPA/RAC, PAP/RAC, IMAP Task Force	Scientific institutions; UNESCO; IOC; CNR	14.1 ; 14.a	
	c) Possible application of modeling and forecasting techniques and tools explored, as available and appropriate.	MED POL	IMAP Task Force		14.2 ; 14.a	MTF

g) MTS Enabling Programme 7: For informed and consistent advocacy, awareness, education and communication

Main activity (means of implementation)	Expected deliverable	Lead Component	Other Component(s)	Partners	SDG Targets	MTF/External Resources/Both
Outcome 7.2. Citizen and general public awareness and outreach raised through citizen science and digital campaigns						
7.2.3. Enhance public awareness and outreach on key MAP topics (in-house expertise, external expertise, Communication TF, digital campaigns, web platforms, outreach events, publications, IT services)	**a)** Digital Campaign for enhancing knowledge of Pollution (i.e web page; interactive story; burning issues; story map; Infographics; Twitter cards; Video; articles and interviews; "focus in" section in MED News).	INFO/RAC	MED POL CU and MAP Components		crosscuting especially SDG 14 Targets	MTF

Monitoring Guidelines/Protocols for sampling and sample preservation of seawater for the analysis of CI13 and C14: concentration of key nutrients and chlorophyll *a*

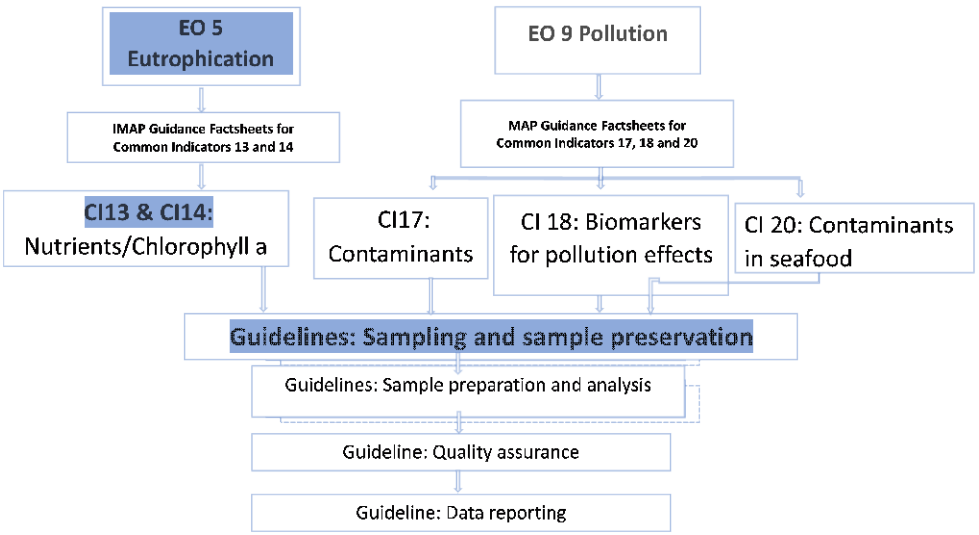
Introduction

1. In the Monitoring Guidelines for sampling and sample preservation of seawater for the analysis of CI13 and C14: concentration of key nutrients and chlorophyll *a*, the protocols for sampling and sample preservation for salinity, nutrients and chlorophyll *a* are elaborated. Sampling and sample preservation are an important step within the monitoring process of the marine environment. Through proper sampling and sample preservation assessment of GES regarding Ecological Objective 5 related to eutrophication as presented in detail in the IMAP Guidance Factsheets (UNEP/MAP, 2019) [73] will be allowed and maintained.

The IMAP Protocols elaborated within this Monitoring Guidelines for sampling and sample preservation of seawater for the analysis of CI13 and C14 regarding concentration of key nutrients and chlorophyll *a* provides detail guidance on the necessary equipment, procedures and identify weak points all endorsed through important notes and possible problems. However, they are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories.

This Monitoring Guidelines builds upon the UNEP/MAP Integrated Monitoring and Assessment Programme (IMAP) respectively IMAP Guidance Fact Sheets for IMAP Common Indicators 13 and 14 (UNEP/MAP, 2019); standardized protocols (UNEP/MAP, 2019a)[74] and Data Quality Assurance schemes (UNEP/MAP, 2019b)[75] in order to allow the comparability of the data and build of regional assessment schemes. They also take into account previous Sampling and Analysis Techniques for the Eutrophication Monitoring Strategy of MED POL (UNEP/MAP/MED POL, 2005)[76], however providing detail procedures that are of relevance for IMAP implementation. With the details of the protocols for sampling and sample preservation the needs of the measurements both in off-shore areas and in narrow coastal areas are addressed.

The below flow diagram informs on the category of this Monitoring Guidelines related to sampling and sample preservation for nutrients and chlorophyll *a* within the structure of all Monitoring guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.



Flow Diagram: Monitoring Guidelines for IMAP Ecological Objective 5 and 9.

Technical note for the sampling of seawater for the determination of hydrographic parameter and the measurement of concentration of key nutrients and chlorophyll *a*

Sampling is an important step within the monitoring process of the marine environment. Although significant efforts have been made in designing procedures for analytical measurements, very little attention has been given to the sampling. Historically, analytical scientists have primarily been concerned with measurements made in the laboratory, and the process of sampling has been conducted by different people, who often even work in different organizations. The analytical scientist's knowledge of the sampling process is therefore sometimes very limited.

Sampling could be defined as a process of selecting a portion of material small enough in volume to be transported conveniently and handled in the laboratory, while still accurately representing the part of the environment sampled. The main difficulties in sampling are representativeness and integrity. Many people think that the analysis starts when the sample arrives in the laboratory. However, sampling is an integral part of the analytical process and sampling is it's starting point. Sampling is so important that, in some cases, it represents the main contribution to the error of the whole analytical process.

Sampling should always start by defining the purpose of the measurement (Stoeppler, 1997[77]). If the different stages are under the responsibility of different people, there needs to be good communication between all parties involved. Sampling planners and analytical scientists need to optimize the whole measurement procedure, including the sampling step. The sampling plan should be written as a protocol that includes the following aspects:

- when, where and how to collect samples;
- sampling equipment, including its maintenance and calibration;
- sample containers, including cleaning, addition of stabilizers and storage;
- sample-treatment procedures (e.g., handling prior to measurements);
- sub-sampling procedures; and
- sample record-keeping (e.g., labelling, recording information, auxiliary information, and chain-of custody requirements).

Sampling frequency is therefore an important factor in terms of representativeness. Low sampling frequency could underestimate the occasional presence of samples with high analyte concentration. Sampling frequency is subject to a number of factors, e.g., transportation, access to the sampling site, the availability of test organisms, and financial constraints.

Under this Technical Note, this Monitoring Guidelines provides the following IMAP Protocols for the sampling of seawater for the determination of hydrographic parameter and the measurement of concentration of key nutrients and chlorophyll a:

- Protocol for the use of a single water sampler attached to a line;
- Protocol for the use of a water sampler attached to a rosette.

Protocol for the use of a single water sampler attached to a line

a. Principle of work

The measurement of salinity and oxygen, nutrients and chlorophyll *a* requires the collection of water samples from various depths. This essential task is achieved with "water bottles". The first water bottle was developed by Fritjof Nansen, the Nansen bottle. It consists of a metal cylinder with two rotating closing mechanisms at both ends. The bottle is attached to a wire. When the bottle is lowered to the desired depth it is open at both ends, so the water flows through it freely. At the depth where the water sample is to be taken the upper end of the bottle disconnects from the wire and the bottle is turned

[77] M. Stoeppler (Ed.), 1997. Sampling and Sample Preparation: Practical Guide for Analytical Chemists, Springer Verlag, Berlin, Germany.

upside down. This closes the end valves and traps the sample, which can then be brought to the surface.

In an "oceanographic cast" several bottles are attached at intervals on a thin wire and lowered into the sea. When the bottles have reached the desired depth, a metal weight ("messenger") is dropped down the wire to trigger the turning mechanism of the uppermost bottle. The same mechanism releases a new messenger from the bottle; that messenger now travels down the wire to release the second bottle, and so on until the last bottle is reached.

The Nansen bottle has now widely been displaced by the Niskin bottle. Based on Nansen's idea, it incorporates two major modifications. Its cylinder is made from plastic, which eliminates chemical reaction between the bottle and the sample that may interfere with the measurement of tracers. Its closing mechanism no longer requires a turning over of the bottle; the top and bottom valves are held open by strings and closed by an elastic band. Because the Niskin bottle is fixed on the wire at two points instead of one (as is the case with the Nansen bottle) it makes it easier to increase its sample volume. Niskin bottles of different sizes are used for sample collection. Nansen and Niskin bottles are used on conjunction with reversing thermometers.

b. Procedure

When the oceanographic cast is lowered to the desired depth, enough time to adapt to the sampling environment must be provided. It is mainly related to the measurement of temperature as the thermometers have to equalize with the local temperature. For digital reversing thermometers 2 minutes is required and 10 minutes for the mercury ones.

After the cast is fired (messenger released) the necessary time to all bottles are closed must be waited.

After the recovery of the bottles, usually they must be put on a sampler holder that provide easy sampling of the content and are not exposed to the direct sunlight, to minimize the heat exchange.

If sampled, the first step is to read the temperature.

The next sub-sampling protocol is maintained:

i) Dissolved oxygen and pH samples using tygon tubing;

ii) Salinity;

iii) then in the order nitrite, other nutrients; and

iv) chlorophyll *a*.

The contamination sources must be avoided:

i) Contamination from the sampling equipment, ship and on- board activities should be avoided while sampling is undertaken. Some details are provided with single parameter.

ii) Sampling bottles should be cleaned with dilute HCL acid and washed with pure water and always be kept closed when not in use.

Protocol for the use of a water sampler attached to a rosette

a. Principle of work

A rosette sampler is made of an assembly of 6 to 36 sampling bottles. Each bottle is a volume that range from a minimum value of 1.2 L to a maximum value of 30 L. All of them constitutes the rosette sampler and are clustered around a cylinder situated in the centre of the assembly where there is a sensing the CTD. The apparatus is attached to a wire rope. A winch on board of the boat unroll the rope during descent and roll up it during the ascent (i.e. at the end of the samples collection). During operations in the ocean, a rosette sampler can approach the seabed at a distance from 1 to 5 m, depending on the particular sea conditions. The opening of each sampling bottle can be automatic (by reaching a certain depth) or manual (by operator, remotely).

b. Procedure

The rosette and CTD is a unique instrument and as many protocols for CTD measurements (WOCE 1991[78], UNESCO 1994[79], UNESCO, 1988[80]) are available and starting from what is suggested by these protocols and taking into account the field experience the protocol as provided hereunder is preferable.

The manufacturer's recommendations on preparations of the CTD and rosette sampler must be followed. If the CTD has not been used for a long time, e.g. the first cast of the cruise, problems with bottles leaking may occur since the O-rings for the bottle's caps are dehydrated. If this is known to happen, it can be prevented by rinsing and filling all bottles with freshwater for at least 1 hour before sampling.

When the CTD is on deck, the CTD pressure is started in the system and temperature is noted in the logbook.

The CTD must be lowered below the sea surface for at least 1 minute before starting the measurements. This gives time for all sensors to acclimatize and air bubbles have time to be flushed out by the pump.

The CTD is bring back to the surface and the measurement of the profile is started. If the sea state is rough, it is recommended to start the downcast from a few meters below the sea surface to prevent bubbles from breaking waves entering the sensors.

Care must be taken to keep the lowering speed as constant as possible, and around 0.5 m s^{-1}. If an Active Heave Compensation (AHC) system is available, a slower speed (0.3 m s^{-1}) can be used.

The CTD as close to the bottom as possible is lowered, though without risking bottom contact. The bottom depth and all the other information required by the CTD log or monitoring protocol are noted.

The rosette bottles should preferably be fired at selected standard depths during the up-cast in order to obtain an undisturbed CTD profile during the down-cast and undisturbed water samples on the way up. If the winch is maneuvered manually between each sampling depth, attention must be paid to approach the set depth as gentle as possible to reduce the disturbance of the water profile. This is especially important in stratified waters.

At each sampling depth the sampling bottles should have time to acclimatize and the effect of dragging water from deeper depth should be avoided. Wait at least 1 minute before the sampling bottles to be fired. If the CTD values still are not stable wait another 3 minutes before firing. If the bottles are equipped with reference sensors do not forget to wait the appropriate time for the sensors to measure after firing the bottle.

However, if the CTD and rosette is equipped and prepared for free-flow sampling bottles, it can be configured to fire water samples on predefined standard depths during the down-cast. Note that samples near the surface should be collected during up-cast to avoid trapping air bubbles mixed into the water by breaking waves and turbulence when the CTD is lowered.

When the CTD is back on deck, the pressure and temperature in the CTD log are noted. The pressure value must be approximately the same as that read before the cast; differences are due to thermal and mechanical hysteresis of the pressure sensor. Deck pressure as offsets to correct pressure is not used. Deck pressure should only be used as consistency check against laboratory measured historical drift.

---

[78] WOCE, 1991.WOCE Operational Manual WHPO 91-1, WOCE Report No68/. (http://whpo.ucsd.edu/manuals.html).
[79] UNESCO, 1994. Protocols for Joint Global Flux Study (JGOFS) Core Measurements. Manual and Guide, 29: 1-181.
[80] UNESCO, 1988. The acquisition, calibration and analysis of CTD data. A report of SCOR Working Group 51. UNESCO Technical Papers in Marine Science, 54: 1-59.

If there is any leakage or malfunction to the CTD, water sampler or water bottles it must be reported. Questionable sensor readouts should also be noted. All events happened during the cast also must be noted. Manufacturer's instructions for cleaning the CTD after each cast must be followed.

Between casts and after the cruise, the CTD and rosette in a way to prevent contamination must be stored.

c. Procedure after CTD/ rosette recovery

After the recovery, the CTD / rosette assembly must be put in a place not exposed to the direct sunlight or covered, to minimize the heat exchange.

The next sub-sampling protocol needs to be maintained:

i) Dissolved oxygen and pH samples using tygon tubing;
ii) Salinity, where sampled for control;
iii) Then in the order nitrite, other nutrients, and
iv) chlorophyll.

The contamination sources must be avoided:

i) Contamination from the sampling equipment, ship and on- board activities should be avoided while sampling is undertaken. Some details are provided with single parameter.
ii) Sampling bottles should be cleaned with dilute HCL acid and washed with pure water and always be kept closed when not in use.

Technical note for the sample preservation of seawater for the determination of hydrographic parameter and the measurement of concentration of key nutrients and chlorophyll *a*

Apart from representativeness, one of the main difficulties in sampling is the preservation of the sample. The initial composition of the sample must be maintained from sampling through to analysis. If this is not the case, the final conclusions will not reflect the initial situation. For all of that, handling and storage of collected samples is of a great importance during sampling.

Proper preservation practices must be followed. Samples requiring preservation should be preserved as soon as possible after collection to maintain the integrity of the sample. Complete and certain preservation of samples, regardless of source, is a practical impossibility. Regardless of the sample nature, complete stability for every constituent can never be fully attained. At best, sample preservation only slows the biological and chemical changes that inevitably continue after the sample is collected. Methods of preservation are intended to retard biological action, retard hydrolysis of chemical compounds and complexes, and reduce volatility of constituents. Preservation methods are limited to pH control, chemical addition, amber or opaque bottles, filtration, refrigeration, and freezing.

9. Under this Technical Note, this Monitoring Guidelines provides the following IMAP Protocols for the sample preservation of seawater for the determination of hydrographic parameter and the measurement of concentration of key nutrients and chlorophyll *a*:

- Protocol for the sample preservation of seawater for the determination of salinity;
- Protocol for the sample preservation of seawater for the determination of concentration of nutrients;
- Protocol for the sample preservation of seawater for the determination of concentration of chlorophyll *a*.

Protocol for the sample preservation of seawater for the determination of salinity

a. Equipment

The equipment for the sample preservation of seawater for the determination of salinity include:

i) Niskin bottles arranged on cable or on a multiple sampler (rosette);

ii) Glass bottles with perfect sealing caps from 120-250 ml (the necessary volume depends on the salinometer in use). To avoid leaks and evaporation, the use of glass bottles with cap and undercap is recommend.

b. Procedure

The sample bottle must be carefully rinsed (at least three times), using the same water as the sample.

The bottle must be filled up to the base of the neck, thus leaving enough space for the eventual thermal expansion of the water.

The cap, the screwing area and the neck of the bottle must be thoroughly rinsed and dried to avoid the formation of salt crystals that could precipitate and dissolve in the sample upon reopening in the laboratory.

The cap and undercap must be thoroughly tighten to avoid evaporation between the time of collection and analysis in the laboratory.

c. Storage of samples

For best results it is preferred to analyse the samples as soon as possible and only when their temperature is in equilibrium with that of the laboratory. Thermal equilibrium is typically achieved in 4-5 hours, but it can be accelerated by ensuring a good flow of air around the bottles or by immersing them in a water bath (Stalcup, 1991[81]). However, if kept at room temperature in bottles well capped, the samples remain unaltered for a few weeks, unless the variations of conductivity due to changes in pH, which can also cause changes in the salinity value to the second decimal place (Grasshoff, 1983)[82]. The tightness and chemical inertia of the bottles are factors determinants for a good conservation of the samples.

d. Important notes

It is advisable to write down the position number on the bottle that collects the sample Niskin bottle on the sampler. This will aid in the sampling phase and will minimize the possibility of collecting the sample on the wrong Niskin.

During the collection of the sample, to avoid contamination, attention must be paid to the water surface dripping from the external parts of the sampler. The same care should be taken in case of rain.

Undercaps should be changed every 2-3 years or when deformations occur.

Protocol for the sample preservation of seawater for the determination of concentration of nutrients

The concentrations of nutrients and other bioactive elements are liable to change due to the activity of microorganisms naturally present in seawater. Therefore, as a rule, samples should not be exposed unnecessarily to light and analysed within a few hours after collection.

Nevertheless, it is sometimes necessary to postpone the analysis for some hours or days because of rough weather or shortage of personnel and laboratory space. There is ample literature on this subject (eg., Kirkwood, 1992[83], 1996[84]; Dore et al., 1996)[85] indicating that no single universal preservation regime will satisfy all requirements. For example, glass containers are not suitable if silicate is to be

determined; in different seasons samples from the same location may contain microorganisms of different species and concentrations, so that a given preservation regime could be effective in spring but not in fall. The following two approaches to preservation are: refrigeration and poisoning.

Freezing (to -20 "C) is the method of choice of many scientists if nutrient samples have to be stored for several weeks or even months (e.g., Macdonald and McLaughlin, 1982[86]; Macdonald et al., 1986[87]; Kremling and Wenck, 1986[88]; Chapman and Mostert, 1990[89]; Kirkwood, 1996). If the samples are visibly turbid, they should be filtered as soon as possible after sampling. Subsamples should be placed in carefully cleaned bottles and frozen, stored and thawed in an upright position. For storage, hard-glass bottles with Teflon-lined screw caps should be used or, preferably, high density polyethylene, polycarbonate or polypropylene bottles. For silicate samples only plastic bottles are recommended. The bottles should only be filled to 2/3 of their volume to prevent squeezing of the liquid through the screw caps during the freezing process. If possible, 'quick-freezing' in liquid nitrogen or in a dry ice-methane slurry (to -20°C within about 20 min) is recommended. The best practice suggests that nutrient samples can be stored for no longer than a month prior to analysis (ISO 5667-3:2012)[90]

The factors that affect the alteration of the samples can be mechanical, physical, chemical, biological and systematic. These drawbacks can be partially overcome by using the following measures:

i. the sample can be stored in disposable scintillation type vials, in high density polyethylene, with a cap suitable for ensuring perfect closure. Polyethylene has the advantage of being resistant to chemical agents and thermal variations, it has a greater mechanical resistance and, from experimental tests, it has been shown that it does not yield and does not absorb substances;

ii. the biological problem can be partially alleviated when the sample is filtered using syringes equipped with swinnex containing glass fiber filters with a pore size <1 µm previously rinsed with plenty of DDW and then, from time to time, with the water of the sample itself;

iii. a single vial is used to determine the concentration of the nutrient to be analysed;

iv. the containers must be washed with 10% HCl, then rinsed with DDW and finally with the sample itself;

v. the sample must be taken directly from the sampling bottle and stored in the dark at a temperature of +4 °C if it is analysed within 24 hours. If the sample is not analysed within this period, it must be frozen at a temperature of -20 °C, taking care to leave the vial upright;

vi. the vial should be filled no more than 3/4 of the volume.

This approach, with contained samples volumes, is more suited when samples are used with an automated analytical method.

Especially on small oceanographic vessels, in order to avoid contamination of the seawater sample with exhaust gas, it is advisable to sample directly from the spout of the water sampler using a 50 mL syringe. In this case, the syringe should be equipped with a Swinnex and two-way taps to facilitate washing of the syringe. The distribution of samples in scintillation vials for storage can be done in the ship's laboratories/environments not contaminated by exhaust gas.

The advantage of the scintillation vials, in addition to the practicality of organizing the vials themselves in specially designed supports, is in the speed of freezing, which is still considered the best conservation procedure. Some operators have verified that the use of vials previously used reduces the

possibility of contamination. Others rinse the vials with a diluted solution of HCl (0.1 M) and allow the vials to dry upside down. In summary, a reliable procedure is to use containers, even new ones, but previously protected from dust or other possible contamination, which must be washed several times with the sample and not completely filled in order to prevent the expansion of the liquid during freezing forcing the frost out of the container.

a. Specific details of sample collection and preservation

The specific details of sample collection preservation are taken from the Reference manual for sampling and analysis techniques for the eutrophication monitoring strategy of MEDPOL (UNEP/MAP/MED POL, 2005) with minor enhancement.

a.1. Orthophosphate - P

Water samples for phosphate analysis should be collected in stoppered glass or "aged" polyethylene bottles of 50 to 100 ml volume directly from the outlet tube of the in-line filter used to collect suspended particulates. The samples are stored in a cool dark place until the analysis can be performed. For phosphate, the analysis should be commenced as soon as possible, preferably within half an hour, certainly before 2 hours and only glass bottles should be used for intermediate storage of the samples. The samples should not be stored in new polyethylene or polyvinylchloride containers since phosphate has been shown to disappear rapidly in these containers. Therefore, aged high-density polyethylene bottles or other plastic e.g. polycarbonate may be satisfactory but all sample containers should be thoroughly tested before use. Once collected, samples should be stored out of the light in a refrigerator until required for the analysis.

The addition of acid to unfiltered samples cannot be recommended since this cause hydrolysis of any polyphosphates and release of phosphate from plankton and bacteria. The addition of all the reagents of the analytical procedure to the sample and postponement of the photometric measurement is also not possible, since arsenic and silicate will also react and cause erroneous phosphate readings.

Summarizing, the storage of samples for the analysis of dissolved phosphate for more than one hour should be avoided.

a.2. Ammonium - N

Samples for ammonium analysis should only be taken and stored in tightly sealed seawater-aged glass or high-density polyethylene bottles, which should only be used for the analysis of ammonia. Filtration of samples should also be avoided, if possible, because it is nearly impossible to obtain filters free of ammonium. Waters with high turbidity frequently contain high concentrations of ammonia and may therefore be diluted before the analysis (the residual turbidity may then be compensated by subtraction of the absorbance of the appropriately diluted sample without addition of reagents).

Ammonium is a nutrient compound, which rapidly undergoes biological conversion, i.e., oxidation into nitrite and nitrate and fixation as amino-bound nitrogen in organisms. The analysis of ammonia should be commenced without delay after sampling. Chemical methods for preservation have been proved unsatisfactory because of the fact that organisms rapidly release ammonia. It is therefore strongly recommended that the ammonia reagents be added within one hour after sampling.

a.3. Nitrite - N

Nitrite is an intermediate compound, which occurs if ammonia is oxidized or nitrate is reduced. The presence of higher amounts of nitrite (> 1.5 µmol L^{-1}) signifies the presence of high bacterial activity in the seawater sample. Storage of samples for nitrite analysis can therefore not be recommended. Chemical preservation (e.g. addition of chloroform) also seems to be unsatisfactory. In turbid waters a filtration step is necessary. Therefore, the sub-sample for nitrite determination directly from the outlet of the in-line filter described above in a 100 - 150 ml glass container must be collected. The nitrite reagents should, if possible, be added to the sample within one hour. Intermediate storage of the sample in glass bottles in a refrigerator for up to 3 hours causes, in most cases, no significant changes in the nitrite content, if the original ammonia level is low (< 0.07 µmol L^{-1}). Samples should be stored in tightly sealed glass or polyethylene bottles only. Sulphide ions have been reported to interfere with

the determination of nitrite and, thus, when hydrogen sulphide is suspected to be present in a sample, the gas should be expelled with nitrogen after the addition of the acid sulphanilamide reagent (Grasshoff et al., 1983).

a.4. Nitrate - N

Nitrate is the final oxidation product of nitrogen compounds. Changes of the original nitrate content of a seawater sample can, therefore, only result from oxidation of ammonia and of nitrite or from adsorption of nitrate to the material of the sample container. Adsorption of nitrate into particles seems to be insignificant since the analytical procedure liberates any nitrate, which may be adsorbed. For reasons yet unknown, the nitrate content of a sample decreases rapidly if stored in polyethylene bottles, and at a level of 1.4 µmol L^{-1} about half of the nitrate disappears within seven days after storage at room temperature. This indicates that only glass or "aged" high-density polyethylene bottles with tight screw caps (preferably with Teflon liners) should be used.

If larger plastic bottles are used for sub-sampling for all nutrient analysis, the amount needed for nitrate should be transferred into a glass or "aged" high-density polyethylene bottle within one hour after the sampling. The analysis should not be delayed for more than 5 hours. In this case the samples should be stored in a refrigerator. If longer storage is unavoidable, the sample should be quickly frozen to -20 °C after the addition of the ammonium chloride buffer solution (Grasshoff et al., 1983).

a.5. Silicate - Si

It is obvious that glass bottles should not be used for storage and analysis of seawater samples for reactive silicate. The sub-sampling for silicate analysis should be performed with plastic bottles (made of polyethylene or polypropylene). A few days storage of the sample in the dark in a refrigerator does not lead to significant changes in the silicate content. However, during seasons of high productivity, do not store them for longer than a day. Polymerization of orthosilicate during storage of frozen samples has been reported from fresh water samples but does not occur in seawater. If kept frozen, it is recommended to thaw the sample gradually at room temperature for at least 24 hours. However, as with all nutrients immediate analysis of sample is the preferred option.

The best procedure for storage and preservation of fresh-water samples seems to be the acidification of the sample with sulfuric acid to a pH of 2.5 and storage in tightly sealed, seawater-aged, high density polyethylene bottles in the dark at about 4 °C. However, as with all nutrients immediate analysis of the sample is the preferred option.

Protocol for the sample preservation of seawater for the determination of concentration of chlorophyll *a*

a. *Equipment and reagents*

The equipment for the sample preservation of seawater for the determination of concentration of chlorophyll *a* include:

i) Dark plastic bottles, 1 L (coastal waters) - 5 L (open sea)

ii) Plankton net with 250 µm mesh

iii) Plastic funnel suitable for bottles

iv) Filtration apparatus (for filters with 25 or 47 mm diameter)

v) Vacuum pump and trap

vi) 25 or 47 mm Whatman GF/F fiberglass filters (recommended)

vii) 10 ml calibrated centrifuge tubes

viii) Freezer or fridge

ix) Automatic sprayer or pipette for acetone

x) 1 L graduated cylinders

xi) Funnel for filtration and filter paper

xii) Acetone, ppa [$(CH_3)_2CO$]

xiii) Anhydrous sodium carbonate [Na_2CO_3]

xiv) Neutralized acetone: pure anhydrous sodium carbonate to the pure acetone (ppa) is added and shaken vigorously. After at least 24 hours, the acetone is filtered through paper and transferred to the hermetically sealed bottle or bottle.

b. Sampling

Water sample from the sampling bottles to the dark plastic bottles, through the net with 250 µm mesh, must be transferred and stored in a cool place, away from sunlight. The prefiltration of the sample is intended to retain zooplankton and fragments of macroalgae possibly present (Strickland and Parsons, 1968[91]; Lenz and Fritsche, 1980[92]).

c. Filtration procedure

Glass fibre filters, Whatman GF/F, are the most suitable for use and filtration must be carried out within a short time from the collection (max 1-2 hours), especially when the samples have been collected in eutrophic environments. The fiberglass filter is less prone to clogging and is cheaper than the synthetic membrane filter and are also used for their high retention capacity, ease of homogenization and versatility.

If the purpose is to estimate precise dimensional fractions of the particulate, filters based on synthetic membranes (polycarbonate) instead of glass fibre filters can be used. These filters, with an enucleation impression, have the advantage of having calibrated pores and therefore guarantee a very precise separation of the particles according to size. However, some disadvantages must be noted, such as the very low retention capacity, much slower filtration flow, making it necessary to distribute the sample on more filters if the sensitivity of the method want to be increased.

The filter is placed in the appropriate housing of the filtration apparatus, wetted and the vacuum pump with slight depression started, to allow it to uniformly adhere to the support.

Using a graduated cylinder, between 0.5 and 5 L of sample are poured into the funnel of the filtration system.

The vacuum pump is started, providing that the pressure difference between the lower and upper part of the filter does not exceed -25 KPa (about 150 mm Hg), to avoid breaking the plant cells with the consequent loss of pigments.

At the end of the filtration the filter the pump is kept running for a few seconds to avoid that a part of the material is lost. The amount of water to be filtered is related to the concentration of pigments (in the open sea where concentrations of chlorophyll *a* to about 1 µg L^{-1} are generally measured about 3 L of sea water must be filtered while in coastal waters, 0.5 - 1 L may be sufficient).

As previously mentioned, algae suspensions must be filtered with a very small pressure difference between the two sides of the filter to minimize cell breakage.

The use of filtration supports that have a valve for the escape of air, not to limit the filtering surface due to the presence of air bubbles and that are tightened with the rotation of a ring nut independent of the upper face of the support, is advisable. Tearing the filter during assembly or disassembly of the support thus will be avoided.

d. Storage of samples

---

[91] Strickland Ld., Parsons T.R., 1968. A practical handbook of sea-water analysis. Bull. Fish. Res. Board Can., 167, 1-312.
[92] Lenz J., Fritsche P., 1980. The estimation of chlorophyll a in water samples: a comparative study on retention in a glass-fibre and membrane filter and on the reliability of two storage methods. Arch. Hydrobiol. Beih., 14: 46-51.

The conservation of the samples is a critical point of the analytical procedure, which can determine the onset of degradation processes of the chlorophylls that lead to their underestimation (Rai and Marker, 1982)[93]. Consequently, to perform the extraction and analysis of chlorophyll pigments immediately after filtering the sample is always preferable.

However, if this is not possible, immediately after filtration the filter is placed in a centrifuge tube with hermetic seal and a known volume of neutralized pure acetone is added to completely submerge the filter (approximately 5 ml). The test tube is then kept in the dark at -20 °C (or in any case at temperatures between -20 and +4 °C), paying particular attention to the tightness of the closure.

Storing the filtered material for a period of time that lasts from a few days to several weeks can have a negative effect, leading to the degradation of chlorophyll pigments (Yanagi and Koyama, 1971[94]; Blasco, 1973[95]; Neveux, 1979[96]; Lenz and Fritsche, 1980; Lazzara et al., 1990[97]; Mantoura et al., 2005[98]).

Alternative methods of storing the filters have been used, which however are not recommended, such as storing at -20 °C after freezing the damp or dried filters (Panella and Magazzù, 1978[99]) or the drying and freezing technique (freeze-drying) which does not give satisfactory conservation results according to Lenz and Fritsche (1980).

The conservation of chlorophyll *a* in microalgae samples collected on a filter has so far been the subject of a very limited number of studies, if the diffusion of the practice of conserving filters, even for prolonged periods (Mantoura et al., 2005) is to be considered. Almost all of the studies date back to before the 1980s, do not concern separate analyses of the extracted pigments and often present contrasting results (Marker et al., 1980)[100] so that no freezing practice can be recommended.

In conclusion, immediate measurements on the extracts is advisable to be carried out or, in the impossibility, the conservation of the filter immersed in pure acetone at -20 °C or better at -80 °C only for periods of less than a month, or of wet filter frozen in air (between -20 °C and -80 °C) but only for periods shorter than the week.

Appendix 11

Monitoring Guidelines/Protocols for Determination of Hydrographic Physical Parameters

1. Introduction

1. In this Guideline for Determination of Hydrographic Physical Parameters the supporting parameters temperature, salinity and transparency are presented. Temperature and salinity are essential in the basic calculation of other parameters as are dissolved oxygen and pH. On the other hand, they also serve as proxy for the definition of the water typology important tool in the water classification scheme on which the assessment of GES is based on as presented in detail in the IMAP Guidance Factsheets (UNEP/MAP, 2019)[101].

The IMAP Protocols elaborated within this Monitoring Guidelines for Determination of Hydrographic Physical Parameters provide detail guidance on the necessary equipment, chemical reagents, analytical procedures along with appropriate methodologies for measurement of the core hydrography physical supporting parameters, calculations, data transformation if necessary and identify weak points, including important specific notes and elaborated possible problems. However, they are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories, which should be tested and accordingly modified, if need be, in order to validate their final results.

This Monitoring Guidelines builds upon the UNEP/MAP Integrated Monitoring and Assessment Programme (IMAP) respectively IMAP Guidance Fact Sheets for IMAP Common Indicators 13 and 14 (UNEP/MAP, 2019); standardized protocols (UNEP/MAP, 2019a)[102] and Data Quality Assurance schemes (UNEP/MAP, 2019b)[103] in order to allow the comparability of the data and build of regional assessment schemes. They also take into account previous Sampling and Analysis Techniques for the Eutrophication Monitoring Strategy of MED POL (UNEP/MAP/MED POL, 2005)[104], however providing detail procedures that are of relevance for IMAP implementation. With the details of the protocols for hydrographic chemical parameters, the needs of the measurements both in offshore areas and in narrow coastal areas are addressed.

In the Subchapters “Symbol, units and precision” at the end of each Protocol, for all parameters described in it, the symbol and unit suggested by the International System of Units (SI) are presented. The expected accuracy, precision and where possible the Limit of Detection (LOD) are also presented. The Method identifiers are also presented as it is provided in the Library P01 of the British Oceanographic Data Centre (BODC) Parameter Usage Vocabulary respectively included in Data Dictionaries and Data Standards for eutrophication built in IMAP Pilot Info System.

The below flow diagram informs on the category of this Monitoring Guideline related to determination of hydrographic physical parameters within the structure of all Monitoring Guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.

Flow Diagram: Monitoring Guidelines for IMAP Ecological Objectives 5 and 9

2. Technical note for determination of temperature and salinity of seawater

Temperature is the property that regulates the transfer of thermal energy or heat between two bodies: the heat flow is directed from the warmer body to the colder one until thermal equilibrium is reached. Temperature measuring instruments are based on this basic principle. The temperature, together with salinity, is useful for identifying the mass of water sampled and for calculating, using an equation of state, the density and other derived quantities. This parameter also has effects on biological systems and in general on the chemical-physical balances in the marine environment, including the solubility of gases (e.g. oxygen solubility) and pH.

Prior to January 1, 1990, the temperature was expressed in the International Practical Temperature Scale of 1968 (IPTS-68). The 1990 International Temperature Scale (ITS-90) was subsequently adopted, which currently represents the best approximation of the thermodynamic temperature (T). In oceanography the convention is to measure the temperature on the Celsius (t) scale, whose unit is °C and with t = T – 273.15. The conversion between the old scale (t_{68}) and the new one (t_{90}) is given by the formula (Saunders, 1990)[105]:

$$t_{68} = 1.00024\ t_{90}$$

Salinity is a measure of the content of dissolved materials in sea water. Together with the temperature it is a parameter of fundamental importance for identifying the mass of water sampled and for calculating the density (using an equation of state) and other derived quantities. It affects other parameters such as dissolved oxygen and has effects on many biological and chemical processes and systems in the marine environment.

[105] Saunders, P., 1990. The International Temperature Scale of 1990, ITS-90. Woce Newsletter, 10, IOS, Wormley, UK.

Absolute salinity (SA) is defined as the ratio between the total mass of materials dissolved in sea water and the total mass of water. SA is very difficult if not impossible to measure directly, because it would be necessary to fully know the composition of sea water. Therefore, in practice, an approximate definition is given, the measurement of which is more easily achievable.

The first practical definition of salinity is that given in 1899 by the International Commission for the study of the oceans led by Prof. Martin Knudsen which established that salinity is the residual mass of salt (measured in grams) per kilogram of sea water, when all the carbonates have been transformed into oxides, the bromides and iodides replaced by chlorides and all the organic substance has been oxidized (Forch et al., 1902)[106]. Since the various components contribute to salinity according to a practically constant ratio and the main component, chloride, is easy to accurately measure by a simple chemical analysis (titration), for a long time the salinity of seawater has been determined indirectly by measuring the mass of chlorides dissolved in the water and using empirical relationships (Forch et al., 1902; Wooster et al., 1969)[107].

The definition of salinity was revised when a technique was developed to be able to determine it from water conductivity measurements. In 1978, the JPOTS (UNESCO, 1981)[108] introduced the Practical Salinity Scale (PSS-78), which defines the practical salinity as a function of the ratio K_{15} between the electrical conductivity of a sample of sea water at temperature t_{68} = 15 °C (defined in the IPTS-68 temperature scale) and at the pressure of a standard atmosphere (101325 Pa in the SI, corresponding to 1013.15 millibar), and that of a solution of potassium chloride (KCl), in which the molar fraction of KCl is 0.0324356, under the same conditions of temperature and pressure. A K_{15} = 1 corresponds to a practical salinity of 35.

At 15 °C, the standard solution of KCl has an electrical conductivity which is equivalent to that of a North Atlantic seawater sample with chlorinity of 19.3740 at the same temperature. This fact guarantees:

- a certain continuity between the salinity measurements in the Practical Scale and the previous ones, which were largely based precisely on the measurement of chlorinity;
- the use of sea water with $K_{15} >> 1$ as a secondary standard for the routine calibration of instruments for measuring salinity.

Practical salinity is a dimensionless quantity, whose order of magnitude coincides with that of Knudsen's definition. Although it is an adopted practice, it is technically wrong to use the abbreviation "psu" (practical salinity units), and this practice should be absolutely avoided. This quantity enters into all the algorithms that are currently in use for calculating the thermodynamic properties of sea water (UNESCO, 1983)[109] and is also the one that is stored in databases.

Under this Technical Note, the Monitoring Guidelines for Determination of Hydrographic Physical Parameters elaborates the three following Protocols:

- Protocol for determination of temperature and salinity using CTD;
- Protocols for the determination of temperature using reversing thermometers;
- Protocol for sample preparation and analysis of salinity using bench salinometer.

2.1 Protocol for determination of temperature and salinity using CTD

The multiparameter probe, the only device with which the simultaneous and *in situ* measurement of temperature, salinity, pressure and any other bio-chemical parameters of interest are allowed. Multiparameter probes for oceanographic measurements have been in use since the middle of the last century. The central unit that incorporates and manages the sensors that measure the quantities of interest is their main part. The probes for the measurement of physical parameters at sea are commonly called CTD, an acronym that summarizes the three basic physical parameters measured (C = Conductivity, T = Temperature, D = Depth, i.e. conductivity, temperature and depth). In reality, CTD probes do not measure depth directly, but provide an indirect measure of it by detecting pressure. CTD probes have a dual use, as profilers, when they are dropped along the water column from the surface to the bottom or to a desired intermediate depth, or as fixed-point sampling instruments (as happens when they are installed on a buoy or on an instrumented anchor). In the first case, the measurement of a vertical profile of the parameters and in the second one a time series at a precise point in space are collected. The vertical resolution of the profile and the temporal resolution are related on the sampling frequency of the instrument.

To check the correct functioning of a CTD system during an oceanographic campaign, it is useful to make comparisons by collecting water samples with a sampler connected to the system, to be analysed with a salinometer and by carrying out temperature measurements using reversing thermometers mounted on the sampler. The pressure values measured by the sensor of the CTD system can be compared with those provided by an independent pressure sensor.

a. Equipment

CTD: preferably be equipped with dual sensors for salinity and temperature, to prevent loss of data and provide a first instance of quality control. For stratified waters CTDs should preferably have a sampling rate of 12 Hz or higher. A CTD equipped with a rosette for water samplers is preferred to individual sampling flasks clamped to a wire. It is recommended that the CTD is mounted vertically within the frame of the rosette frame to avoid fouling of sensors by debris or bubbles and promote free flow of water.

Reversing thermometers, mounted on the rosette frame or on samplers from which reference data for temperature is obtained.

Sampling bottles attached to the CTD-rosette or attached on a line from which reference samples for bench salinometers are obtained.

b. Procedure

Many protocols for CTD measurements (WOCE 1991[110], UNESCO 1994[111], UNESCO, 1988[112]) are available. Starting from what is suggested by these protocols and taking into account the field experience the following protocol is preferable:

The manufacturer's recommendations on preparations of the CTD and rosette sampler must be followed. If the CTD has not been used for a long time, e.g. the first cast of the cruise, problems with bottles leaking may occur since the O-rings for the bottle's caps are dehydrated. If this is known to

[110] WOCE, 1991.WOCE Operational Manual WHPO 91-1, WOCE Report No68/. (http://whpo.ucsd.edu/manuals.html).
[111] UNESCO, 1994. Protocols for Joint Global Flux Study (JGOFS) Core Measurements. Manual and Guide, 29: 1-181.
[112] UNESCO, 1988. The acquisition, calibration and analysis of CTD data. A report of SCOR Working Group 51. UNESCO Technical Papers in Marine Science, 54: 1-59.

happen, it can be prevented by rinsing and filling all bottles with freshwater for at least 1 hour before sampling.

When the CTD is on deck the system is started and the CTD pressure and temperature in the logbook noted.

The CTD must be lowered below the sea surface for at least 1 minute before starting the measurements. This gives time for all sensors to acclimatize and air bubbles have time to be flushed out by the pump.

The CTD is bring back to the surface and the measurement of the profile started. If the sea state is rough it is recommended to start the downcast from a few meters below the sea surface to prevent bubbles from breaking waves entering the sensors.

Care must be taken to keep the lowering speed as constant as possible, and around 0.5 m s^{-1}. If an Active Heave Compensation (AHC) system is available, a slower speed (0.3 m s^{-1}) can be used.

The CTD as close to the bottom as possible is lowered, though without risking bottom contact. The bottom depth and all the other information required by the CTD log or monitoring protocol are noted.

The rosette bottles should preferably be fired at selected standard depths during the up-cast in order to obtain an undisturbed CTD profile during the down-cast and undisturbed water samples on the way up. If the winch is maneuvered manually between each sampling depth, attention must be paid to approach the set depth as gentle as possible to reduce the disturbance of the water profile. This is especially important in stratified waters.

At each sampling depth the sampling bottles should have time to acclimatize and the effect of dragging water from deeper depth should be avoided. Wait at least 1 minute before the sampling bottles to be fired. If the CTD values still are not stable wait another 3 minutes before firing. If the bottles are equipped with reference sensors do not forget to wait the appropriate time for the sensors to measure after firing the bottle.

However, if the CTD and rosette is equipped and prepared for free-flow sampling bottles, it can be configured to fire water samples on predefined standard depths during the down-cast. Note that samples near the surface should be collected during up-cast to avoid trapping air bubbles mixed into the water by breaking waves and turbulence when the CTD is lowered.

When the CTD is back on deck, the pressure and temperature in the CTD log are noted. The pressure value must be approximately the same as that read before the cast; differences are due to thermal and mechanical hysteresis of the pressure sensor. Deck pressure as offsets to correct pressure is not used. Deck pressure should only be used as consistency check against laboratory measured historical drift.

If there is any leakage or malfunction to the CTD, water sampler or water bottles it must be reported. Questionable sensor readouts should also be noted. All events happened during the cast also must be noted. Manufacturer’s instructions for cleaning the CTD after each cast must be followed.

Between casts and after the cruise; the CTD and rosette in a way to prevent contamination must be stored. All sensors should be treated and stored according to the manufacture’s recommendations.

Reference data for temperature is obtained from reversing thermometers, mounted on the rosette frame.

CTD-rosette or line; It is recommended that reference samples are collected in triplicates. For general requirements for sampling, preservation, handling, transport and storage of water samples, chapter

1.2.1. Protocol for the sample preservation of seawater for the determination of salinity must be consulted.

c. Symbol, units and precision

For the parameters described in this protocol, the symbols and units suggested by the International System of Units (SI), as well as the expected accuracy, along with the Method identifiers as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Depth:

Symbol: *z* **Unit**: m

Precision: Pressure sensor: ± 0,01 m

Method identifier: SDN:P01::**DEPHPR01** Depth (spatial coordinate) relative to water surface in the water body by profiling pressure sensor and conversion to seawater depth using UNESCO algorithm

Temperature:

Symbol: *t* **Unit**: °C (degree Centigrade)

Precision: Temperature sensor: ± 0,01 °C

Method identifier: SDN:P01::**TEMPCC01** Temperature of the water body by CTD and verification against independent measurements

Salinity:

Symbol: *S* **Unit**: -

Precision: Conductivity sensor: ± 0,01

Method identifier: SDN:P01::**PSALCC01** Practical salinity of the water body by CTD and computation using UNESCO 1983 algorithm and calibration against independent measurements

2.2 Protocols for the determination of temperature using reversing thermometers

2.2.1 Digital electronic reversing thermometers

The digital reversing electronic thermometer can perform the same functions as the mercury one, but with higher precision. Having the same dimensions of the mercury one it enters the housings provided for this type of thermometer. In this thermometer the temperature is measured by a platinum thermometer similar to the sensors used on the CTD probes. The advantages are that it does not use mercury, it covers a larger range of measurement, reading is easier because it is provided in digital form reducing the risk of loss of data, it is robust and easy to use.

a. Procedure

The thermometers are placed in the special thermometer holders with which the sampling bottles are equipped. In thermometer holders without a locking mechanism, the thermometers must be locked using para or neoprene rubber cylinders, usually supplied with thermometer holders, which cushion any mechanical shocks.

With the thermometer holder armed, a small magnet (supplied with the thermometer or common) is slid three times along the major axis of the thermometer, until on the display shows written "Samp"; in this way the thermometer is set in reversing mode. For information, the "Cont" mode is used to display the instantaneous temperature measured in real time by the thermometer, while the "Hold" mode displays the temperature data recorded after reversing the thermometer, while it was in "Samp" mode.

The bottles with the thermometers must be kept at the programmed depths for the time necessary to reach the balance with the surrounding medium. The time required for digital thermometers is about 30 seconds. Then the command to close is send the bottle and to reverse the thermometer and wait at least ten seconds after the closing confirmation signal before changing deep or to retrieve the bottle.

Once the bottles are brought back to the surface, sliding the long magnet once along the major axis of the thermometer, the temperature value will appear on the display for a few seconds recorded by the thermometer during the reversal.

The data are written in a form, reporting the serial number for each thermometer.

2.2.2 Mercury reversing thermometers

Mercury reversing thermometers consist of a main and a secondary thermometer, coupled in a glass container that protects them from mechanical changes induced by the water pressure. The main thermometer has a relatively large mercury tank that communicates, by means of a serpentine strangled in one point (called "break-off point") with a thin capillary ending with a small widening which constitutes a secondary tank. When the thermometer is in a straight position, at the desired depth, the mercury contained in the main tank changes volume according to the external temperature and occupies part of the thin capillary. When the thermometer overturn, due to the considerable surface tension, the mercury contained in the capillary breaks in the coil at the height of the choke and separates from the rest. The amount of mercury that separated, collected in the secondary tank and in part of the capillary, indicates the water temperature at the time of reversing. The auxiliary thermometer, mounted next to the reversing thermometer, is used to measure the ambient temperature, once the thermometer is brought back to the surface. **NOTE:** The use of mercury is prohibited except in exceptional cases.

a. Procedure

The thermometers are placed in the special thermometer holders with which the sampling bottles are equipped. In thermometer holders without a locking mechanism, the thermometers must be locked using para or neoprene rubber cylinders, usually supplied with thermometer holders, which cushion any mechanical shock.

The bottles with the thermometers are kept at the programmed depths for the time necessary to reach balance with the surrounding medium. The time required for mercury thermometers is 5-10 minutes. The reversing of the thermometer is then triggered.

The bottles are then returned to the surface and placed on a special support, making sure that are not directly affected by the sun, possibly covering them with a wet towel to avoid large fluctuations in temperature.

Once the balance between the temperature of the thermometers and the ambient temperature has been reached, using the appropriate eyepiece, the water temperature is read on the main thermometer (t'') with accuracy to one hundredth of a degree or higher in relation to the characteristics of the scale.

Similarly, on the auxiliary thermometer, the air temperature (t'_a) is read with tenth degree precision. The eye must be in level with the upper part of the mercury column, to avoid errors due to refraction.

The data are written in a form, reporting the serial number for each thermometer.

b. Calculations

The reading provided by the thermometer, for the error caused by the capillary imperfections must be corrected proceeding as indicated in the calibration certificate that accompanies the thermometer. In the certificate, for temperature ranges of 5 °C, the correction to be made to the value read on the thermometer to obtain the real temperature value, or the value of the actual temperature at a given temperature value read, is reported. The temperature value read on the thermometer will probably not exactly match those indicated on the certificate, therefore first must be calculated the correction to be made to this value by applying a simple linear relationship between read values and real values. From the manufacturer's tables the values t''_{inf} and t''_{sup} within which the reading (t'') is included and the corresponding correct values t'_{inf} and t'_{sup}, are read and the correct temperatures for the main thermometer t' and for the auxiliary thermometer t'_a calculated from the following equations:

$$t' = t'_{inf} + (t'' - t''_{inf})\ (t'_{sup} - t'_{inf}) / (t''_{sup} - t''_{inf})$$

$$t'_a = t'_{a,inf} + (t''_a - t''_{a,inf})\ (t'_{a,sup} - t'_{a,inf}) / (t''_{a,sup} - t''_{a,inf})$$

t'and t'_a are inserted in the following equation:

$$c = (V_0 + t') / (t' - t'_a) / [K - ½\ (t' - t'_a) - (V_0 + t')]$$

where:

c = correction to be made,

K = inverse of the thermal expansion coefficient of the glass with which the thermometer is built.

V_0 = volume of mercury at 0 °C expressed as °C (=the degree volume).

The values of K and V_0 are obtained from the calibration certificate.

The water temperature *in situ* is calculated from the formula:

$$t_w = t' + c$$

c. Important notes related to both types of reversing thermometers

All reversing thermometers, regardless of type, must be calibrated with a reference thermometer at least once a year. The reference thermometers must in turn be properly calibrated. Calibration must take place in thermostated baths.

Mercury thermometers must be treated gently, avoiding sharp strokes as they can cause microfractures in the capillary compromising its functioning; digital electronic thermometers are less delicate, but like all electronic instruments, they must be treated with care.

For mercury thermometers, if mercury does not return to the tank, avoid the common practice of gently tap the thermometer, because this causes small damages to the capillary. The reunification must be produced by forcing the expansion of mercury with a heat source.

The main malfunction that mercury thermometers may face concerns the possibility that during the reversal the mercury contained in the capillary will break at a height other than the "break-off point". This can happen due to the presence of bubbles formed by residual gas remained inside the thermometer during construction. This gas should remain confined at the upper end of the

thermometer, in the secondary tank, but it can happen that a bubble penetrates the column of mercury, causing it to break in the wrong place. To avoid the problem, the thermometers must be stored and transported in a vertical position (with the main tank down) and handled gently.

d. Symbol, units and precision:

For the parameter described in this protocol, the symbol and unit suggested by the International System of Units (SI), as well as the expected accuracy, along with the Method identifiers as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Symbol: *t* **Unit**: °C (degree Centigrade)

Precision: Mercury reversing thermometer: ± 0,01 °C

Digital electronic thermometer: **Accuracy:** ±0,0001 °C

Method identifier:	SDN:P01::**TEMPRTNX**	Temperature of the water body by reversing thermometer
	SDN:P01::**TEMPR601**	Temperature (IPTS-68) of the water body by reversing thermometer
	SDN:P01::**TEMPR901**	Temperature (ITS-90) of the water body by reversing thermometer

2.3 Protocols for sample preparation and analysis of salinity using bench salinometer

a. Equipment

The equipment for for sample preparation and analysis of salinity include: i) a laboratory salinometer; ii) IAPSO standard water bottles.

b. General analytical procedure:

b.1 Preparation

The salinometer must be turned on well in advance (at least two hours before the analysis), to stabilize the operation of its electrical parts and, when present, the temperature of the thermostatic bath.

Two bottles of standard water and the samples must be bring in the vicinity of the salinometer with which the measurement is carried out and allow a certain period of time to pass until they reach the same temperature.

b.2 Standardization

The measuring cell must be rinsed at least ten times with sea water with a salinity of about 35. There are bottles of water with these characteristics on the market, alternatively the standard water residues used in previous operations can be used.

The standard water bottles must be shacked carefully and gently to homogenize their contents, avoiding the formation of bubbles.

The standard water bottle must be opened and inserted into the salinometer sampling device.

The measuring cell must be rinsed at least four or five times with standard water.

The measuring cell is then filled with standard water and the salinometer standardized according to the procedure indicated by the manufacturer.

At least two or three measurements of the same standard water must be carried out, unloading and filling the cell each time and checking that the salinity value read after standardization coincides with the salinity value indicated on the standard bottle. If the value does not match, the standardization procedure with a new bottle of standard water must be repeated.

b.3 Measurement

With repeated overturning of the bottle the sample is homogenize avoiding too vigorous shaking not to allow the formation of air bubbles.

The measuring cell must be rinsed with the sample at least four or five times.

The measuring cell is filled with the sample and the outputs read.

The measuring cell is unloaded and filled again with the sample for new reading.

The operation referred to in the previous point is repeated until the difference between two consecutive readings is not less than the level of precision declared by the manufacturer of the instrument.

c. Calculations:

Having determined the conductivity ratio, R_t, between the sample and the standard water at temperature t_{68} (expressed on the IPTS-68 scale), the practical salinity is calculated according to the following equation, valid in the interval for S [2,42] (UNESCO, 1983):

$$S = a_0 + a_1 R_t^{1/2} + a_2 R_t + a_3 R_t^{3/2} + a_4 R_t^2 + a_5 R_t^{5/2} + \Delta S$$

where

$$\Delta S = (b_0 + b_1 R_t^{1/2} + b_2 R_t + b_3 R_t^{3/2} + b_4 R_t^2 + b_5 R_t^{5/2}) \cdot (t_{68} - 15)/[1 + k(t_{68} - 15)]$$

t_{68} is expressed in °C. The temperature in the ITS-90 scale is converted in t_{68} with the equation,

$$t_{68} = 1.00024 \cdot t_{90}.$$

The values of constants are listed below:

a_0	=	0,0080	b_0	=	0,0005	k	= 0,0162
a_1	=	-0,1692	b_1	=	-0,0056		
a_2	=	25,3851	b_2	=	-0,0066		
a_3	=	14,0941	b_3	=	-0,0375		
a_4	=	-7,0261	b_4	=	0,0636		
a_5	=	2,7081	b_5	=	-0,0144		

d. Important notes

Depending on the salinometer in use for the measurement, the procedure indicated may require some modification. It is recommended to check it, following the instructions in the instrument's instruction manual.

The formation of air bubbles in the sample during the pouring or mixing of the sample itself must be avoided. If this happens, the problem can be solved emptying and refilling the cell.

In the presence of deposits and / or air bubbles on the internal components of the measuring cell during use, washing attempts by pumping soapy water or weakly acid solutions into the cell must be avoided, because in addition to the possibility of being ineffective in solving the problem, can have a negative effect on factory calibration and instrument standardization. In the case, the cell must be repeatedly rinsed with deionized water. If the problem persists, the cell can be removed carefully, disassembled and cleaned as indicated in the instrument's instruction manual.

It is recommended to repeat the standardization procedure at least once a day with which the stability of the measuring apparatus electronics is maintained. If variations in the standardization values is observed, it is advisable to check the quality of the standard water bottle in use by repeating the operation with a new bottle. If the variations persist, it may be that the salinometer needs maintenance and needs to be sent to the service company.

The exposure to the air of standard water must be minimized.

For each sample, the time taken to obtain a valid measurement must be limited to the minimum time necessary as the minimum number of readings, avoiding that the volume used falls below the minimum necessary for the analysis.

The use of standard water bottles from the same batch for the same campaign is recommended, otherwise it is necessary to take into account the differences between batches as described by Mantyla (1987)[113] to correct the final salinities. In addition, if the bottles are older than two or three years, it is recommended to compare them with fresher standards to highlight any changes in conductivity due to aging.

e. Symbol, units and precision

For the parameter described in this protocol, the symbol and unit suggested by the International System of Units (SI), as well as the expected accuracy, along with a Method identifier as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Salinity:

Symbol: *S* **Unit**: -

Precision: Conductivity sensor: ± 0,01

Method identifier:	SDN: P01::**PSALBSTX**	Practical salinity of the water body by bench salinometer and computation using UNESCO 1983 algorithm

[113] Mantyla, A.W., 1987. Standard seawater comparison. J. Phys. Oceanogr., 17: 543-548.

3. Technical note for measuring Secchi depth

Water transparency serves as an index for the trophic state of a water body. It reflects eutrophication through changes in the phytoplankton abundance; increase in the ambient nutrient status in the water leads to higher phytoplankton biomass that diminishes the propagation of light in the water. Water transparency is approached by Secchi depth (Cialdi and Secchi 1865[114], Whipple 1899[115]). Secchi depth is influenced by dissolved and/or colloidal inorganic and organic substances as well as total suspended solids and resident seston. It is thus affected by substances unrelated to eutrophication as well.

Secchi depth relates to primary production by being a proxy for the thickness of the euphotic zone wherein the large bulk of the gross production takes place. In principle, the euphotic depth is twice Secchi depth, but this relation varies largely in practice (French et al., 1982)[116].

Under this Technical Note, the Monitoring Guidelines for Determination of Hydrographic Physical Parameters elaborate the IMAP Protocol for measuring Secchi depth.

3.1 Protocol for measuring Secchi depth

The methodology is based on the ISO 7027-2:2019[117] standard.

a. Equipment:

Testing disk (Secchi disk). A white disk with a diameter of 30 cm. The disk should weigh at least 1.7 kg to descend quickly and not be affected by horizontal water movements. Should the disk be lighter, an additional weight can be fastened to the down-facing side of the disk. As the observed Secchi depth tends to increase with the diameter of the disk (Aas et al., 2014)[118], the disks of other sizes are not advised to be used.

Measuring tape/rope of non-elastic material. Depth[119] recognition:

- colour-coded marks at 10 cm intervals. The upper side of the disk equals 0 cm. Half and full meters should be marked to be easily distinguishable.
- depth indicator of a winch.

Weight for waters with currents, fixed in the middle of the down-facing side of the disk.

Optional devices for suppression of reflections, e.g., polarized glasses for the observer.

---

[117] ISO 7027-2:2019 Water quality — Determination of turbidity — Part 2: Semi-quantitative methods for the assessment of transparency of waters.
[118] Aas, E., Høkedal, J., Sørensen. K., 2014., Secchi depth in the Oslofjord–Skagerrak area: theory, experiments and relationships to other quantities. Ocean Science 10: 177–199.
[119] Secchi depth measurement is dependent on the observer's eyesight, and any aids for vision tend to increase Secchi depth, which should be considered, e.g., in the context of long-term data series.

b. Measuring:

The observer should try to ensure that the measuring rope stays in an as upright position as possible. Deviations from the upright position stem from water currents and waves as well as ship's movement and thruster operation.

The Secchi depth is measured on the shaded side of the ship to avoid direct sunlight reflections from the water surface. However, the observer must consider the source of error in the shaded side that occurs whenever the Secchi depth stretches beyond the shade of the ship. In this case, the disk is suddenly lighted by the sun and a higher reading will be attained.

Enough time must to be allowed (preferably 2 min) when looking at the disc near its extinction point for the eyes to completely adapt to the prevailing luminance level. The disc must be lowered further until it is no longer visible. The achieved depth is to be read and written down. After that, the disc is lowered by another 0.5 m. Then, during a slow elevation, the disc becomes visible as a greenish-bluish spot. The achieved depth is to be read and written down. It is recommended to repeat the test two times as a minimum. The Secchi depth is the arithmetic average of all readings.

The precision of a Secchi measurement depends on the turbidity of the water. In the waters of high turbidity, the precision can approach 0.1 m under calm seas. In clearer waters, the precision ranges from 0.2 to 0.5 m, depending on actual conditions (e.g., waving or sun glitter).

c. Important notes

Secchi depth determination is sensitive to weather conditions:

- *Waving:* Optimally, Secchi depth should be measured when the sea is relatively calm. Waving introduces a source of error in the Secchi measurement by worsening the overall visibility, and waves > 0.5 m in height obscure the identification of the actual surface. The length reading of the rope at the surface should be judged to be an average of the extreme values due to waving. The determination of Secchi depth is not meaningful in high seas.

- *Sunlight:* Secchi depth should be determined to avoid direct sunlight reflections from the water surface. Sun glitter decreases the Secchi depth estimation irrespective of optical properties of water; on the average by 12% (Aas et al., 2014).

The length markings of the rope should be checked and made clearer annually. The rope should be changed whenever it stretches > 5%.

d. Symbol, units and precision

For the parameter described in this protocol, the symbol and unit suggested by the International System of Units (SI), as well as the expected accuracy, along with a Method identifier as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Symbol: z_{SD} **Unit:** m

Precision: 0.2-0.5 m

Method identifier: SDN:P01::**SECCSDNX** Visibility in the water body by Secchi disk

Appendix 12

Monitoring Guidelines/Protocols for Determination of Hydrographic Chemical Parameters

1. Introduction

1. In this Monitoring Guidelines for Determination of Hydrographic Chemical Parameters the supporting chemical parameters dissolved oxygen and pH are elaborated. Dissolved oxygen (DO) is an essential component which determines the water quality and trophodynamics of an aquatic system. On the other hand, the pH today is important mainly due to the acidification process: when CO_2 is absorbed by seawater, a series of chemical reactions occur resulting in the increased concentration of hydrogen ions (pH). This process has far reaching implications for the ocean and the creatures that live there.

The IMAP Protocols elaborated within this Monitoring Guidelines for Determination of Hydrographic Chemical Parameters provide detail guidance on the necessary equipment, chemical reagents, analytical procedures along with appropriate methodologies for measurement of the core hydrography chemical supporting parameters, calculations, data transformation if necessary and identify weak points, including important specific notes and elaborated possible problems. However, they are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories, which should be tested and accordingly modified, if need be, in order to validate their final results.

This Monitoring Guidelines builds upon the UNEP/MAP Integrated Monitoring and Assessment Programme (IMAP) respectively IMAP Guidance Fact Sheets for IMAP Common Indicators 13 and 14 (UNEP/MAP, 2019)[120]; standardized protocols (UNEP/MAP, 2019a)[121] and Data Quality Assurance schemes (UNEP/MAP, 2019b)[122] in order to allow the comparability of the data and build of regional assessment schemes. They also take into account previous Sampling and Analysis Techniques for the Eutrophication Monitoring Strategy of MED POL (UNEP/MAP/MED POL, 2005)[123], however providing detail procedures that are of relevance for IMAP implementation. With the details of the protocols for hydrographic chemical parameters, the needs of the measurements both in offshore areas and in narrow coastal area are addressed.

In the Subchapters “Symbol, units and precision” at the end of each Protocol, for all parameters described in it, the symbol and unit suggested by the International System of Units (SI) are presented. The expected accuracy, precision and where possible the Limit of Detection (LOD) are also presented. A Method identifier is also presented as it is provided in the Library P01 of the British Oceanographic Data Centre (BODC) Parameter Usage Vocabulary respectively included in Data Dictionaries and Data Standards for eutrophication built in IMAP Pilot Info System.

The below flow diagram informs on the category of this Monitoring Guidelines related to determination of hydrographic chemical parameters within the structure of all Monitoring guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.

2. Technical note for measuring dissolved oxygen

The concentration of dissolved oxygen (DO) present in sea water depends on physico-chemical factors that determine the solubility of the gas and on biological activities (photosynthesis and respiration). Knowing temperature and salinity of the water, it is possible to trace the concentration of the theoretical dissolved oxygen which does not consider the processes of organic production and consumption. The positive (over-saturation) or negative (under-saturation) imbalance between the experimentally obtained and theoretical oxygen concentration is often used as an estimate of the processes prevalent in the water column, i.e. the prevalence of oxygen production by photo-synthetic processes, or consumption by the processes of mineralization of organic debris. From a precise determination of the DO concentration it is therefore possible to estimate the net production and respiration of the planktonic community.

Under this Technical Note, the Monitoring Guidelines for Determination of Hydrographic Chemical Parameters elaborate the Protocol for sample preparation and analysis of dissolved oxygen in seawater by Winkler method.

2.1. Protocol for sample preparation and analysis of dissolved oxygen in seawater by Winkler method

The Winkler titration method for the determination is based on the method developed by Winkler in 1888 (Winkler 1888)[124]. The method has seen several modifications to encompass interferences, and the basic method today for the determination of oxygen concentration is the one prepared by Grasshoff

[124] Winkler, L.W., 1888. Die Bestimmung des in Wasser gelösten Sauerstoffen. Berichte der Deutschen Chemischen Gesellschaft, 21: 2843–2855.

(1983)[125]. It is an iodometric titration, in which the amount of oxygen in the sample is determined indirectly via iodine. It is the most precise and reliable titrimetric procedure for DO analysis.

Briefly: A divalent manganese solution is added followed by strong alkali to a water sample in a glass stoppered bottle. Any DO present in the sample rapidly oxidizes an equivalent amount of the dispersed divalent manganous hydroxide precipitate to hydroxides. The sample is then acidified with H_2SO_4. In the presence of iodide ions in an acidic solution, the oxidized manganese reverts to the divalent state, with the liberation of iodine equivalent to the original DO content. The iodine is then titrated with sodium thiosulfate and starch as an indicator. For the analysis of field samples, DO analysis is best done in the field, as there is less chance for the sample to be altered by atmospheric equilibration, changes in temperature and chance of escape of gasses.

a. Sample preparation

a1. Equipment

The equipment for sample preparation of dissolved oxygen in seawater by Winkler method include:

i) Transparent plastic tube (e.g. Tygon) to be connected to the sampling bottle taps;
ii) 60-90 ml pyrex bottles, BOD type, with ground flute beak or rounded truncated cone cap. Each bottle must have been pre-calibrated for its closed cap volume with an accuracy of ± 0.1ml;
iii) Laboratory glassware;
iv) Dispenser, automatic micropipettes or polyethylene syringes with notches every 0.5 mL;
v) Insulated container, shielded from light;
vi) 100 mL volumetric flasks;
vii) 6 bottles for the determination of the reagent blank. These bottles must be selected from those with a known volume used for the withdrawal of oxygen, preferably so that they are two by two of equal volume (± 0.1 mL), and with a difference in volume between one pair and the next of 1 ± 0.1 mL.

a.2. Chemicals

The following reagents and chemicals are needed:

i) manganese chloride [$MnCl_2 \cdot 4H_2O$] or manganese sulphate [$MnSO_4 \cdot H_2O$];
ii) sodium hydroxide [NaOH] or potassium hydroxide [KOH];
iii) potassium iodide [KI].

a.3. Preparation of reagents

Solution of Mn_2^+ (R1)

40 g of $MnC1_2 \cdot 4H_2O$ or 35 g of $MnSO_4 \cdot H_2O$ is dissolved in 80 ml of reagent grade water and adjusted to volume in a 100 mL flask. The reagent, if stored in a closed bottle and not inadvertently contaminated with R2 containing iodide, is stable indefinitely.

Alkaline solution of ion I^- (R2)

20 g of sodium hydroxide or 30 g of potassium hydroxide is dissolved in 40 mL of reagent grade water. 60 g of potassium iodide is dissolved in 40 ml of reagent grade water. The two solutions are gradually mixed in a flask and adjusted to a final volume of 100 mL with H_2O. The solution should

[125] Grasshoff, K., 1983. Determination of oxygen. In: Grasshoff, K., Ehrhardt M., Kremling K. (eds), Methods of Seawater Analysis, Verlag Chemie, Weinheim: 61-72.

then be stored in a dark, well-capped plastic bottle. If it is not contaminated with R1 or with reducing or oxidizing agents, it is stable indefinitely.

a.4. Procedure

The sub-sampling of DO from the Niskin bottle, or similar, must be done quickly as the dissolved gas tends to balance itself with the atmosphere. This process will be further accelerated by the temperature difference existing between the sample and the environment.

For sub-sampling, the transparent plastic tube to the Niskin bottle, possibly with a diameter of no more than 5 mm and a length that can easily reach the bottom of the BOD bottles for sample collection is connected.

The bottles, previously cleaned from the residues of the previous samplings and analyzes, are rinsed with water from the sample to be analysed. To prevent the formation of a layer of supersaturated oxygen along the walls the bottles are not shacked vigorously.

The sample is allowed to flow into the bottle, checking that the filling tube is free of air bubbles and avoiding the bubbling of air in the sample. The sampling tube must touch the bottom of the bottle, which must be filled slowly by overflowing a quantity of water equal to at least half of its total volume.

The tube is slowly removed from the bottle, always letting the water flow, so that the bottle always remains full to the brim. Before adding the reagents, it is checked that no air bubbles are trapped in the bottle, otherwise the bottle is emptied, and the filling operation repeated.

In the case bottles for BOD of about 100 ml is used, 0.5 mL of R1 and 0.5 mL of R2 is added in rapid succession, using two automatic dispensers or two normal syringes equipped with a long and narrow needle in order to inject the reagents at least below the free surface of the sample, preferably at the bottom of the bottle. In the case bottles for BOD with a volume other than about 100 ml are used proportional volumes of R1 and R2 are added.

The cap is carefully inserted avoiding the formation of air bubbles between the cap and the liquid, letting excess water escape. The well capped bottle is shacked inverting it several times for at least 30 seconds.

The bottles are placed in a dark place at a temperature similar to that of sampling. After the precipitate settle for 2/3 of the volume the bottles are shacked again. To further limit the possibility of gas exchange with the environment, it is suggested to keeps the cap firmly pressed on the neck of the bottle, using for example rubber bands, adhesive tape, etc.

Sampling for the determination of the reagent blank

Pre-selected bottles for blanks are sampled from the same sampling bottle, preferably not from the one relating to the surface level.

One dose of each reagent is added to the lowest volume pair of bottles, two doses to the volume greater than 1 mL and three doses to the volume greater than 2 mL. This operation must be carried out at least once during a sampling day.

a.5. Sample storage

The fixed samples should be stored in the dark and at a temperature as close as possible to that of sampling and analysed within the day of sampling.

Theoretically, the fixed samples could be kept for a longer time if there were no gaseous diffusion through the closures of the corks which unfortunately occurs, albeit to different degrees, in all bottles. In order to reduce this phenomenon, it is customary to keep the bottles, well closed, completely immersed in water of the same origin temperature as the sample.

b. Analytical procedure

b.1. Equipment in the laboratory

The equipment for analysis of dissolved oxygen in seawater by Winkler method includes:

i) 1 L class A volumetric flasks
ii) 1 mL or 5 mL glass or piston microburette
iii) 5 Pyrex bottles of the same type as those used for sampling
iv) 0.500 mL precision micropipette; 0.200 mL micropipette
v) Fluorescent lamp with opaque screen or diffuser
vi) Cold magnetic stirrer
vii) Magnetic stirrers
viii) 2 automatic dispensers or micropipettes or polyethylene syringes with notches every 0.5 mL (for oxygen reagents)
ix) 1 mL dispenser (for concentrated sulfuric acid).

An alternative to the micro burette is:

i) Potentiometric titrator;
ii) Combined redox platinum electrode, semi-micro.

b.2. Chemicals

The following reagents and chemicals are needed:

i) Sodium thiosulfate [$Na_2S2O_3 \cdot 5H_2O$];
ii) Potassium iodate [KIO_3], possibly ultrapure;
iii) Sodium chloride [NaCI];
iv) Chloroform [$CHC1_3$] or sodium-azide [NaN_3];
v) Soluble starch;
vi) Concentrated sulfuric acid, analytical grade [H_2SO_4].

b.3. Preparation of reagents

Thiosulfate solution ~ 0.1 mol L^{-1} (or ~ 0.1 M)

24.82 g of $Na_2S_2O_3 \cdot 5H_2O$ are dissolved in 800 ml of reagent grade H_2O in a 1 L volumetric flask and adjusted to the mark. Few drops of chloroform or sodium azide are added as a stabilizer.

The solution should be stored in a dark glass bottle. Since thiosulfate is involved in numerous redox reactions, the solution is relatively unstable and therefore must be standardized against the potassium iodate solution before and after use. It is possible to use pre-stabilized commercial vials of thiosulfate solution of known titre.

KIO_3 standard solution 0.01667 mol L^{-1} (or 0.01667 M)

About 5 g of iodate are dried in an oven at 110 °C for at least an hour and cooled in the dryer or taken directly from a stock that was once dried and stored cold in a dryer in the presence of a strong dehydrator. Exactly 3.567 g are weighted and them dissolved quantitatively in 800 mL of reagent

grade water in a 1 L volumetric flask (class A). The solution is adjusted exactly to volume at a temperature around the flask calibration (usually 20-25 ° C). Commercial iodized standard vials are also available.

The solution must then be stored in tightly capped dark glass bottles, kept away from the sun and opened for the shortest time possible only for sampling. Under these conditions the standard solution is to be considered stable for at least one year.

Stabilized colloidal starch solution (starch weld)

A saturated solution of sodium chloride by dissolving approximately 350 g of it in 1 L of distilled water in a beaker is prepared. 10 g of soluble starch in the saturated sodium chloride solution is hot dissolved.

The solution should be kept in a dark bottle and can be used until it becomes cloudy and flocculates.

b.4. Preparation of standard solutions

5 BOD bottles are filled to 3/4 of the volume at least with sea water or with distilled water and 0.5 mL of concentrated sulfuric acid, 0.5 ml of R2 and 0.5 mL of reagent R1 are added to each one in succession using the same dispensers used to "fix" the samples. It is preferable to carry out these operations under continuous stirring, allowing the complete mixing of each reagent before adding the next. The bottles can then be capped and stored in the dark until the iodate standard solution is added;

Exactly 10.00 mL of standard KIO_3 solution to each bottle using an automatic pipette are added;

The bottle is shacked a few seconds and placed in the dark for about 1 minute to allow the reaction of iodate dismutation to take place by producing molecular iodine. The standards are then titrated with the thiosulfate solution as indicated below for the samples.

b.5. Analysis of samples

Dissolution of the precipitate

The bottle number and its volume are recorded;

The cap is gently removed from the bottle containing the precipitate and placed on the switched off magnetic stirrer;

A magnetic stir bar is quickly inserted into the bottle trying to lift as little precipitate as possible, add 0.5 mL of concentrated sulfuric acid with a dispenser, the stirrer is started by adjusting its speed in order to avoid the formation of vortices and turbulence;

When the complete dissolution of the precipitate (the solution becomes a clear yellowish colour due to the presence of iodine) is achieved, as sun as possible the titration with sodium thiosulfate is performed.

Titration

The tip of the burette containing the thiosulfate solution is immersed in the bottle containing the sample or standard;

At the beginning the thiosulfate solution is added rapidly, and then the flow is slowed when the yellow colour of the sample clears and, importantly, and it is stopped before the total disappearance of the yellow colour.

When the solution is almost colourless, the lamp is turned on and about 0.2 mL of starch solution is added (an intense purple colour appears), the addition of thiosulfate is resumed slowly until the blue colour almost disappears.

After few seconds, when viewed transparently against diffuse fluorescent light, a faint dispersed colour like a cloud is displayed in the bottle. The titration is proceeded very slowly until the complete disappearance of the colour, the end point (EP) of the titration. The volume of added thiosulfate is recorded.

If an automatic titrator with combined redox / platinum electrode is used, the titration program must show a decrease in the titrant flow near the EP which will correspond to the inflection point of the titration curve.

c. Calculations

c.1. Standardization of thiosulfate (C_{tio})

The prepared KIO_3 standards are titrated with the ~ 0.1 M thiosulfate solution (see "Preparation of reagents").

The molar titre C_{tio} of the thiosulfate solution is:

$$c_{tio} = 6 * (V_{KIO3} * c_{KIO3}) / V_{tio}$$

where

c_{tio} = exact molar concentration (M) of the $Na_2S_2O_3 \cdot 5H_2O$ solution

V_{KIO3} = volume in mL of injected KIO_3 standard (see "Preparation of standard solutions")

c_{KIO3} = molar concentration (0.01667 M) of the KIO3 standard used

V_{tio} = volume in mL of thiosulfate required to titrate the standard

The mean and standard deviation of V_{tio} in the replicates must be calculated and any value that differ by more than two standard deviations from the mean discarded. The mean and standard deviation of V_{tio} which will be used in the calculation of c_{tio} must be recalculated with the new values.

c.2. Determination of the reagent blank

The 3 pairs of bottles dedicated to the determination of the blank must be titrated and the volume of thiosulfate used noted. The concentration of DO (see "Calculation of dissolved oxygen concentration") must be calculated as if the blank (c_{bl}) were zero. The slope of the correlation line between the concentrations of DO thus obtained and the volume of R1 + R2 added corresponds to the blank of the reagents (c_{bl}).

A simpler way would be to calculate the difference between the average values for each pair of bottles and the next, but given the considerable variability in the differences this method is to be used in the alternative. This procedure allows the determination of the reagent blank, not that of the sample blank, i.e. the presence in the sample of interfering chemical substances (e.g. iodate) capable of producing elemental iodine in the acidified solution. If the desired level of accuracy required it, the blank should

also be measured for each sample, according to the procedure suggested by Tijssen and van Bennekom (1989)[126].

c.3. Calculation of the micro-molar concentration (M or µmol L^{-1}) of dissolved oxygen

The following equitation applies for calculation of the micro-molar concentration (M or µmol L^{-1}) of dissolved oxygen:

$$c(O_2)/\mu mol\ L^{-1} = [(c_{tio} \cdot V_{tio}) / (4 \cdot (Y\text{-}y)) \cdot 10^6] - c_{bl}$$

where:

c_{tio} = exact molar concentration of the $Na_2S_2O_3 \cdot 5H_2O$ solution, from the standardization procedure

V_{tio} = volume in mL of thiosulfate required to titrate the unknown sample

c_{bl} = reagent blank (see reagent blank determination)

Y = volume in mL of the specific BOD bottle used for each sample

y = total volume, in mL, of reagents R1 + R2 added to each sample bottle (in the case shown, 1 mL)

c.4. Transformations :

The transformation of units needs to follow below provided scheme:

The next numerical equation must be used

$$c(O_2, \text{Unit A}) = c(O_2, \text{Unit B}) \cdot \text{Conversion factor}$$

Unit A	**Unit B**	**Conversion factor**
mg L^{-1}	mL L^{-1}	0.6997637
mg L^{-1}	µmol L^{-1}	0.0319988
mL L^{-1}	µmol L^{-1}	0,0223916

d. Dissolved oxygen expressed as a percentage of the saturation value

The calculation of the percentage of the saturation value can be made only by knowing the value of the oxygen solubility in the sea water sample that has been analysed. It is known that the solubility of a gas in a liquid depends not only on the properties of the solvent (composition and temperature), but also on the partial pressure exerted on the solution by the gas in question (Henry's law). The solubility value therefore corresponds to the amount of oxygen that would dissolve in water in conditions of equilibrium between the surface layer of the sea and the atmosphere above.

To determine it, reference is made to a sample in thermodynamic equilibrium with a gaseous mixture of composition equal to the standard atmosphere, at the pressure of a standard atmosphere (mole fraction of oxygen = 0.20946) and saturated with water vapor. Depending on whether the oxygen concentration is related to the unit of mass or volume of the solvent, two concentration values are obtained, called USAC (acronym for "Unit Standard Atmospheric Concentration). These values are represented by the symbols C_0^i and C_0* according to the symbology introduced by Benson and Krause

[126] Tijssen S.B., Van Bennekom A.J., 1989. High precision determination of dissolved oxygen. ICES C.M. 1989/c:6, Annex C: 11-12.

(1980[127], 1984[128]). These quantities have recently been recalculated on the basis of a more rigorous procedure introduced by the authors themselves and subsequently recommended by UNESCO (Millero, 1986)[129] to replace the values contained in the UNESCO oceanographic tables (1973)[130] which were based on the Weiss algorithms (1970)[131].

The equation is the product of numerical interpolations of data obtained from equations that more rigorously calculate the needed quantities. Furthermore, it should be noted that the equation is based on the practical temperature scale of 1968 (IPTS-68) and therefore, if values measured on the basis of the ITS-90 scale are used, the appropriate conversions must be applied.

d.1. Calculations

The following equitation applies for calculation of Dissolved oxygen expressed as a percentage of the saturation value:

$$\varphi(O_2/O_2') = 100 \cdot c(O_2)/C_0$$

where

$$\ln C_0 = a_0+a_1/T+a_2/T^2+a_3T^3+a_4/T^4 - S\cdot(b_0+b_1/T+b_2/T^2)$$

In the equation C_0 corresponds to the concentration of the theoretical DO C_0^i and C_0^* reported per unit of volume. The constants to be inserted in the equation are:

$a_0 =$ -135.90205
$a_1 =$ $1.575701 \cdot 10^5$
$a_2 =$ $-6.642308 \cdot 10^7$
$a_3 =$ $1.243800 \cdot 10^{10}$
$a_4 =$ $-8.621949 \cdot 10^{11}$
$b_0 =$ 0.017674
$b_1 =$ -10.754
$b_2 =$ 2140.7

e. Important notes

When fixing the samples contact between the reagents R1 and R2 must be avoided.

During manual titration, the same criterion for identifying the titration EP for both standards and samples must be used, best avoiding changing operator.

---

[127] Benson B.B., Krause D. Jr., 1980. The concentration and isotopic fractionation of gases in freshwater in equilibrium with atmosphere. Limnol. Oceanogr., 25: 662-671.
[128] Benson B.B., D. Krause, Jr., 1984.The concentration and isotopic fractionation of oxygen dissolved in freshwater and seawater in equilibrium with atmosphere. Limnol. Oceanogr., 29: 620-632.
[129] Millero F.J., 1986. Solubility of oxygen in seawater. UNESCO Technical Papers in Marine Science, 50: 13- 17.
[130] UNESCO. 1973. International oceanographic tables, Vol. 2. NIO-UNESCO, Paris.
[131] Weiss, R.F., 1970. The solubility of nitrogen, oxygen and argon in water and seawater. Deep-Sea Research, 17: 721–735.

The titration must be performed quickly, decreasing the flow of thiosulfate only in the vicinity of the titration EP, in order to minimize errors due to the photo-oxidation of the iodide and the reduction of iodine by the starch.

f. Possible problems

A problem that usually occurs is the formation of bubbles in the bottle containing the sample; to prevent this phenomenon, the bottles must be washed with detergents and rinsed thoroughly.

Sometimes an air bubble is formed under the cap of the bottle containing the sample already fixed; in this case, the possible existence of an error due to the excess, however not quantifiable, of the amount of dissolved oxygen must be considered and noted.

g. *Symbol, units and precision*

For the parameters described in this protocol, the symbols and units suggested by the International System of Units (SI), as well as the expected accuracy, along with the Method identifiers as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Concentration of dissolved oxygen

Symbol: $c(O_2)$ **Unit:** µmol L^{-1}

Precision: 0.1

Method identifier:	SDN:P01::**DOXYWITX**	Concentration of oxygen {O2 CAS 7782-44-7} per unit volume of the water body [dissolved plus reactive particulate phase] by Winkler titration

Saturation of Dissolved Oxygen

Symbol: $\varphi(O_2/O_2')$ **Unit:** % *(percent)*

Precision: 0.1

Method identifier:	SDN:P01::**OXYSBW01**	Saturation of oxygen {O2 CAS 7782-44-7} in the water body [dissolved plus reactive particulate phase] by Winkler titration and computation from concentration using Benson and Krause algorithm

3. Technical note for measuring pH

Since ocean acidification is a growing concern, monitoring of pH is necessary for studies of acidification and its effects on the carbonate buffer system. As many important biological processes are likely to be affected by rapid changes in pH, it is important to include accurate determination of pH among monitoring parameters.

pH is operationally defined, and several pH scales are used in environmental monitoring. The NBS (National Bureau of Standards) scale is suitable for waters of low ionic strength and used for freshwater monitoring. The total hydrogen ion scale is often used for pH determinations in oceanic waters.

pH is also used in marine environmental monitoring as a co-factor in measurements of primary production.

Two different principles for pH measurement are available, based on potentiometric and spectrophotometric detection. Potentiometric detection has the advantages of being fast and simple and requires no advanced or expensive equipment. Buffers used for calibration should ideally have an ionic strength matching that of the samples, which is challenging when an area with a large salinity gradient is monitored. Several pH meters, electrodes and buffers are commercially available.

Spectrophotometric detection is more accurate, has a higher precision, but requires expensive equipment. It is widely used in measurements under oceanic conditions, but less in estuarine waters. Since commercial applications for the spectrophotometric methods are not widely used; users must assemble instruments and software for data processing. Methods based on spectrophotometric detection are therefore not yet recommended for monitoring purposes.

Therefore, under this Technical Note, the Monitoring Guidelines for Determination of Hydrographic Chemical Parameters elaborates the two following Protocols: i) the Protocol for sample preparation and analysis of pH using a potentiometric method; and ii) the Protocol for sample preparation and analysis of pH using a spectrophotometric method.

3.1. Protocol for sample preparation and analysis of pH using a potentiometric method

pH is measured using a glass/combined electrode. The total hydrogen ion scale should be used. Temperature is measured and recorded both during pH measurement and at sampling depth.

Subsamples for pH should be drawn from sampler bottles as early as possible (after samples for oxygen and hydrogen sulphide, but before samples for nutrients and salinity) to avoid gas exchange between water and air. Samples should be collected in gas-tight bottles. Bottles should be rinsed thoroughly with sample water before filling. Bottles are filled with a laminar flow of sample water, allowing 2-3 bottle volumes to overflow before capping. Bottles should be completely filled, leaving no headspace. Avoid trapping bubbles of air when capping bottles. Samples should preferably be analysed as soon as possible directly after sampling.

Determination of pH using a glass electrode is described in ISO 10523[132].

Temperature must be monitored and controlled during calibration of instrument and analysis, preferably by use of a tempered water bath. Make sure temperature of buffers and samples is constant (±1 °C) during the process. To maintain constant temperature, select a bath temperature slightly above ambient temperature (for normal room temperature, set bath temperature to 25 °C – in a cooler environment 20 °C may have to be used). pH analysis can also be made in + 15 °C in a cooling bath which has been shown to produce comparable results.

pH meter should be calibrated daily when in use. Manufacturer's instructions for a 2-point calibration (pH 7 and pH 9 are recommended) are followed. NBS buffers for calibration is used. Attention to expiry dates of buffers has to be paid.

Electrode and temperature probe must be rinsed with deionized water and wiped between buffers/samples.

[132] ISO 10523: Water quality – Determination of pH.

Electrode must be allowed to equilibrate in sample water for 15 minutes before first measurement. The best is if equilibrium is reached for each sample before recording a reading.

Open-cell measurements allow gas exchange between sample and air during the time of measurements. Closed-cell measurements eliminate the interferences.

Manufacturer's instructions must be followed for handling and storage of electrodes. Electrodes may require cleaning and conditioning when exposed to samples from intense plankton blooms. Anoxic water containing high concentration of hydrogen sulphide may shorten the life of electrodes.

A correction for in situ pH (Gieskes, 1969)[133] is sometimes applied. A better option is to report measured pH, temperature from pH measurement and in situ temperature.

pH values from potentiometric detection should be reported with two decimals. Temperature from measurement and sampling depth should also be reported.

Information on which pH scale is used must be included in metadata.

A detailed analytical protocol for the analysis of pH using a potentiometric method (Dickson et al, 2007)[134] is presented in the Annex I. (Guide to best practices for ocean CO_2 measurements, Ch: 4. Recommended standard operating procedure, SOP6a: Determination of the pH of sea water using a glass/reference electrode cell).

a. Quality control

Laboratories carrying out analyses of pH should have established a quality management system according to ISO 17025[135].

Data for samples for estimation of measurement uncertainty (repeated measurements from a sample, multiple subsamples from different samplers closed at same depth).

An internal reference material (IRM) should be analysed daily.

It is strongly recommended that all laboratories participate in interlaboratory comparisons and proficiency testing programs, to provide external verification of laboratory performance. Proficiency testing for pH in environmental waters are provided by e.g. SYKE. More proficiency testing schemes are listed at www.eptis.bam.de.

Validation of the adopted method needs to be performed on the relevant matrix and concentration range e.g. by taking part regularly at intercomparison studies or proficiency testing schemes.

Measurement uncertainty should be estimated using ISO 11352[136].

Estimation should be based on within - laboratory reproducibility, IRM, and, if available, data from proficiency testing and CRM.

b. Symbol, units and precision

For the parameter described in this protocol, the symbol and unit suggested by the International System of Units (SI), as well as the expected accuracy, along with a Method identifier as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Symbol: *pH* **Unit:**

Precision: ± 0,003 **Accuracy:** -

Method identifier: SDN:P01:: **PHXXPR01** pH per unit volume of the water body by pH electrode

3.2. Protocol for sample preparation and analysis of pH using spectrophotometric method

Recently, the spectrophotometric method of measuring the pH value of seawater has been proposed, which consists in measuring the visible absorption of a coloured pH indicator added to the seawater sample. The measurement is precise, sensitive, and theoretically free from the need for calibrations (of calibration lines), but the instrumentation is more expensive and the analysis speed lower than the potentiometric method (Dickson 1993)[137]. As précised before, this method is therefore not yet recommended for monitoring purposes. To compare the pH values obtained by this method with the potentiometric ones, it must be referred to the total hydrogen ion concentration pH scale.

A detailed analytical protocol for the analysis of pH using spectrophotometric method recommended by the International Scientific Community (IOC and SCOR) collected in Dickson et al., 2007 is presented in the Annex II. (Guide to best practices for ocean CO_2 measurements, Ch: 4. Recommended standard operating procedure, SOP6b: Determination of the pH of sea water using the indicator dye *m*-cresol purple).

a. Symbol, units and precision

For the parameter described in this protocol, the symbol and unit suggested by the International System of Units (SI), as well as the expected accuracy, along with a Method identifier as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Symbol: *pH* **Unit:**

Precision: 0.001 **Accuracy:** ± 0.005

Method identifier: SDN:P01:: **PHXXSP01** pH per unit volume of the water body by spectrophotometry

Monitoring Guidelines/Protocols for Determination of Concentration of Key nutrients in Seawater – Nitrogen Compounds

1. Introduction

1. In the Monitoring Guidelines for Key nutrients – Nitrogen compounds in Seawater, the protocols for manual and automated determination of the concentration nitrite, nitrate and ammonium are elaborated. Probably the most important property of seawater in terms of its effect on life in the marine environment is the concentration of dissolved nutrients. The most critical of these nutrients are nitrogen and phosphorus because they play a major role in stimulating primary production by plankton. These elements are known as limiting because plants cannot grow without them. At the moment, the water classification scheme on which the assessment of GES regarding Ecological Objective 5 related to eutrophication is based on chlorophyll *a* concentration as presented in details in the IMAP Guidance Factsheets (UNEP/MAP, 2019) [138] , although in near future it will be complemented by those based on concentration of key nutrients in seawater.

The IMAP Protocols elaborated within this Monitoring Guidelines for Determination of Concentration of Key nutrients in Seawater – Nitrogen Compounds provide detail guidance on the necessary equipment, chemical reagents, analytical procedures along with appropriate methodologies for measurement of the concentration of nitrite, nitrate and ammonium in seawater, calculations, data transformation if necessary and identify weak points all endorsed through important notes and possible problems. However, they are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories, which should be tested and accordingly modified, if need be, in order to validate their final results.

This Monitoring Guidelines builds upon the UNEP/MAP Integrated Monitoring and Assessment Programme (IMAP) respectively IMAP Guidance Fact Sheets for IMAP Common Indicators 13 and 14 (UNEP/MAP, 2019); standardized protocols (UNEP/MAP, 2019a)[139] and Data Quality Assurance schemes (UNEP/MAP, 2019b)[140] in order to allow the comparability of the data and build of regional assessment schemes. They also take into account previous Sampling and Analysis Techniques for the Eutrophication Monitoring Strategy of MED POL (UNEP/MAP/MED POL, 2005)[141], however providing detail procedures that are of relevance for IMAP implementation. With the details of the protocols for determination of Key nutrients, the needs of the measurements both in offshore areas and in narrow coastal areas are addressed.

In the Subchapters “Symbol, units and precision” at the end of each Protocol, for all parameters described in it, the symbol and unit suggested by the International System of Units (SI) are presented. The expected accuracy, precision and where possible the Limit of Detection (LOD) are also presented. A Method identifier is also presented as it is provided in the Library P01 of the British Oceanographic Data Centre (BODC) Parameter Usage Vocabulary respectively included in Data Dictionaries and Data Standards for eutrophication built in IMAP Pilot Info System.

The below flow diagram informs on the category of this Monitoring Guidelines related to determination of concentration of key nutrients in seawater respectively concentration of nitrogen compounds in seawater within the structure of all Monitoring guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.

e. Continuous flow methods

The principle used by the continuous segmented-flow auto-analysers (SFA) is recognized as the most reliable and accurate method for determination of nutrients. Different systems are available and can be configured to meet the standard methods such as ISO, EPA, ASTM, etc… Wherever possible it is

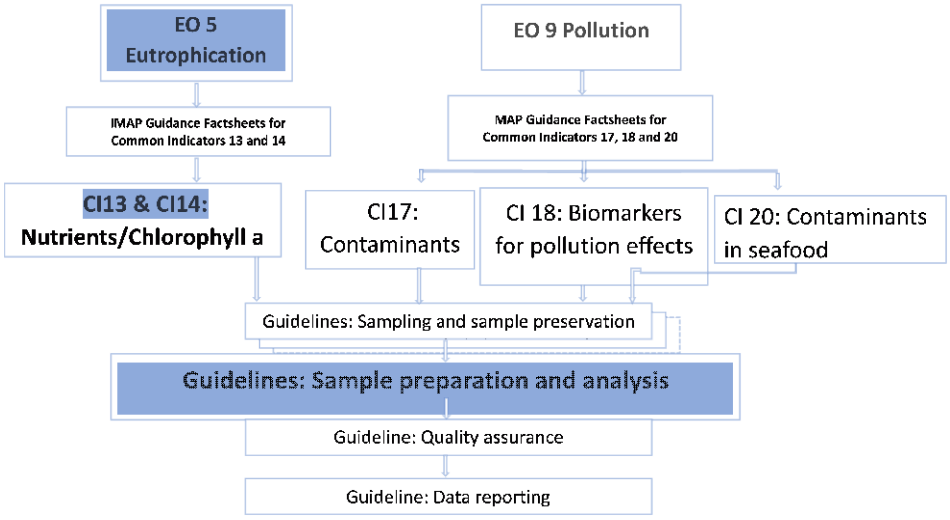
strongly recommended that such analysers are used because of the considerable increase in precision and sample throughput that they offer. Ideally such analysers can be used in laboratories on board a research vessel allowing problems of sample deterioration during storage to be circumvented.

The multiplicity of methods reported in the literature is more related to the optimization of methods for different environments that a significant difference in the reactions used. In the Protocols dedicated to the individual methods, some specific aspects will be mentioned. On the general principles of SFA systems, in addition to the documentation provided by the manufacturers to the classic textbooks of Strickland and Parsons (1965)[142] and Grasshoff et al. (1999)[143] can be referred. Equally numerous are the technical reports of the various laboratories produced to homogenize the methods within the programs international like JGOFS or WOCE. In the Protocols only the most essential indication on the most frequently used method will be provided. Important notes on the critical parts of the methods, for it successful performance will also be indicated.



Flow Diagram: Monitoring Guidelines for IMAP Ecological Objective 5 and 9.

2. Technical note for determination of concentration of nitrite

This technical note elaborates the method for determination of concentration of nitrite that is based on a series of reactions that lead to the formation of a coloured diazo compound and measured colorimetrically. This procedure, one of the most sensitive among direct colorimetric analyses, is specific for nitrites and does not show any variation in efficiency in relation to the ionic strength of the solution. The original method, proposed by Griess-Ilosvay (Ilosvay, 1889)[144], was subsequently modified by Shinn (1941)[145] and applied to the analysis of sea water by Bendschneider and Robinson (1952)[146].

The analytical procedure is based on the formation, in an environment with a pH lower than 2 and a temperature not higher than 40 °C, of a diazonium salt (diazosulfanilamide chloride) which subsequently reacts with naphthylethylenediamine to generate a diazo dye.

Under this Technical Note, this Monitoring Guidelines provides the following IMAP Protocols for the colorimetric determination of concentration of nitrite:

- Protocol for manual colorimetric determination of concentration of nitrite;
- Protocol for automated colorimetric determination of concentration of nitrite.

2.1 Protocol for manual colorimetric determination of concentration of nitrite

f. Equipment:

The equipment for manual colorimetric determination of concentration of nitrite include:

1. graduated cylinders or 50 mL pipettes
2. 100 mL borosilicate glass containers (beaker)
3. laboratory glassware for chemical preparations
4. 1 mL automatic dispenser
5. 500 mL volumetric flasks
6. volumetric flasks of 100 mL class A
7. 1 L class A volumetric flask
8. precision micropipettes to measure volumes in the range of 10-100 µL
9. analytical scale
10. stove
11. microwave oven
12. dryer
13. spectrophotometer or colorimeter sensitive to 543 nm equipped with cells of at least 50 mm optical path

g. Chemical products:

The chemical products for manual colorimetric determination of concentration of nitrite include:

1. sulfocromic mixture
2. concentrated hydrochloric acid [HCl]
3. sulfanilamide [$NH_2SO_2C_6H_4NH_2$]
4. *N*-(1-Naphthyl)ethylenediamine dihydrochloride [$C_{10}H_7NHCH_2CH_2NH_2 \cdot 2HCl$]
5. sodium nitrite [$NaNO_3$]
6. chloroform [$CHCl_3$]

h. Preparation of stock solutions:

Sulfanilamide reagent

50 mL of concentrated hydrochloric acid is poured into a beaker of at least 600 mL, containing 400 mL of reagent grade water, and stirred until completely mixed. 5 g of sulfanilamide in this solution are dissolved. The volume with reagent grade water is adjusted to 500 ml. The solution is stable for many months if stored in plastic or glass containers, in the refrigerator.

NNEDDC reagent

500 mg of *N*-(1-Naphthyl) ethylenediamine dihydrochloride in 450 mL of reagent grade water is dissolved and adjusted to volume with reagent grade water in a 500 mL flask. The solution stored in the refrigerator, in dark bottles, is stable for 1-2 months and must be discarded if brown colour is developed.

Standard solution of sodium nitrite - 2 mmol L^{-1}

Few grams of sodium nitrite in an oven at 110 °C are dried and cooled in a silica gel dryer. 138 mg are weighted on an analytical balance, and in 800 mL of reagent grade water in a 1 L (class A) flask dissolved and adjusted to volume. The solution should be kept refrigerated, in a dark bottle, adding a few drops of chloroform and is stable for about a month.

i. Preparation of specific equipment for analysis:

d.1. Maintenance of reaction vessels

The reaction flasks with boiling sulfochromic mixture are periodically washed, rinsed abundantly with reagent grade water and them dried. For ordinary maintenance, after use, are rinsed with reagent grade water and placed upside down on filter paper.

j. Analytical procedure:

e.1.Reagents to be prepared at the time of use

Preparation of standard solutions

5 standards of known nitrite concentration are prepared: by diluting, in 100 mL flasks (class A), respectively 10, 25, 50, 75, 100 µL of standard solution of sodium nitrite (measured with a precision pipette) with oligotrophic seawater. The concentrations of nitrite are thus between 0.2 and 2 µmol L^{-1} plus the nitrite content of oligotrophic seawater.

e.2. Analytical treatment

At the time of analysis, if the sample had been frozen, possibly using a 37 °C bath or in a microwave oven is quickly thawed;

The beakers with 50 mL of sample or each of the standards (measured with a graduated cylinder) are filled.

1 mL of sulfanilamide reagent to each sample or standard with a dispenser are added and the reaction allowed to take place for 5 minutes.

1 mL of NNEDDC reagent to each sample or standard with a dispenser are added and the reaction allowed to take place for additional 10 minutes.

e.3. Preparation of reagent blanks

At least two replicates of reagent blanks in the same type of 100 mL borosilicate glass container, using 50 mL of reagent grade water are prepared applying the same procedure as for samples and standards.

e.4. Spectrophotometric measurements

The absorbance of the blank ($bl_{c,\,i}$) of each cell of the spectrophotometer or colorimeter, used for reading against the reference cell, at 543 nm is measured, both filled with water without regents. The operation is superfluous if only one cell is used.

For each flask, the number of the cell used, the identification of the contents of the flask (sample, standard solution, blank) are noted in a form. The cell is rinsed with part of its contents, filled and the absorbance at 543 nm read, recording the reading on the same form.

k. Calculations

The reagent blank (bl) as the average of the two blank readings is calculated.

The correlation between the absorbance values of the 5 standards and the assumed concentrations, using the Ordinary Least-Squares Regression is calculated. The colorimetric factor (f) is represented by the slope.

The concentration of nitrite in the samples is calculated with the following equation:

$$c(NO_2^-) \,/\, \mu mol\ L^{-1} = (ABS - bl - bl_{c,\,i})\ f$$

where

$c(NO_2^-)$ = concentration of orthophosphates

ABS = absorbance of the sample

bl = blank of the reagents

$bl_{c,\,i}$ = blank of the i-th cell used

f = colorimetric factor

For a cell with a 50 mm optical path, the colorimetric factor is equal to about 4.0 µmol L^{-1}, i.e. a difference in concentration of 1 µmol L^{-1} (for example between standard solution 3 and 5) should be the difference in absorbance of about 0.25.

l. Important notes:

The standard stock solution is renewed frequently (at least once a month).

m. Possible problems:

The suggested method is trouble- and interference-free. However, any hydrogen sulfide present in the sample must be removed before analysis (Grasshoff, 1983[147]; Airey et al., 1984[148]).

2.2 Protocol for automated colorimetric determination of concentration of nitrite

a. Reagents

Sulfanilamide reagent

10 g of sulfanilamide in 100 ml of concentrated HCl is dissolved and adjusted to one liter with DDW. The solution should be stored in a dark glass bottle and is stable at least 1 month.

NNEDDC reagent

1 g of *N*-(1-Naphthyl) ethylenediamine dihydrochloride in 950 mL of reagent grade water is dissolved and adjusted to volume with DDW in a 1000 mL flask. The solution stored in the refrigerator, in dark bottles, is stable for 1-2 months and must be discarded if brown colour is developed.

b. Standard

About 2 g of $NaNO_2$ is dried in an oven at 100 °C, checking the weight of the salt remain constant over time. The salt is placed in a silica gel dryer for additional 24 hours. 138 mg are weighted on an analytical balance, and in 800 mL of DDW in a 1 L (class A) flask dissolved and adjusted to volume. A final concentration of 2 mmol L^{-1} is obtained. The solution should be kept refrigerated, in a dark bottle, adding a few drops of chloroform and is stable for about a month.

This standard is used in the daily procedure for the preparation of 5 standards. The concentration of the standards is chosen based on the amount of NO_2 salt expected to be found covering the entire range of expected concentrations. From the 5 standards the multiplication factor necessary to calculate the concentrations is obtained.

c. Manifold

The manifold (Fig. 1) is composed of two injectors and four coils of 10 turns each. The first injector (A) is equipped with 3 inputs: the first is for the sample, the second is for the air and the third input provided for the introduction of the first reagent. Immediately after there are 4 composite coils with 10 coils each: in the first 2 the first reagent is mixed, in the other 2 the second reagent is introduced at point (B), by means of the second injector.

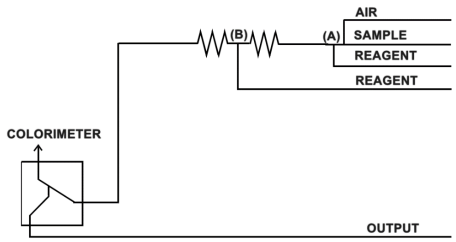

Figure 1. Manifold for nitrite measurement.

d. Important notes:

[147] Grasshoff, K. (1983) Determination of nitrite. In: "Methods of Seawater Analysis", Grasshoff K., M. Ehrhardt, K. Kremling Eds, Verlag Chemie, Weinheim, 139-142.
[148] Airey D., Dal Pont G., Sandars G. (1984) A method of determining and removing sulphide to allow the determination of sulphate, phosphate, nitrite and ammonia by conventional methods in small volumes of anoxic waters. Analytica Chim. Acta, 166, 79-92.

If an unstable baseline appears when the device is turned on in the absence of reagents, wash the circuit with 10% HCl.

If during the analysis there is an evident increase in the baseline, clean immediately the colorimeter reading cell by injecting 50% hydrochloric acid directly into the cell without stopping the circuit.

Use DDW water by deionizing it directly in the sample container of the instrument.

If it is necessary to change components of the circuit (injectors, bubblers), rebalance the circuit by changing the flow rates of the pipes.

Use suitable containers for the different reagents to be used. The container cap must be provided of small holes in which to insert capillaries (needles, etc.) for the withdrawal of the reagent.

Nutrient-poor water, i.e. oligotrophic water (OSW), as wash water between samples is used. OSW of salinity similar to the samples must be used.

e. Symbol, units and precision

For the parameter described in this protocol, the symbol and unit suggested by the International System of Units (SI), as well as the expected accuracy, along with the Method identifiers as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Symbol: $c(NO_2^-)$	**Unit:** μmol L^{-1}	
Precision: ±0.02	**Accuracy:** ± 0.02	**LOD:** 0.03
Method identifier:	SDN:P01::**NTRIMATX**	Concentration of nitrite {NO2- CAS 14797-65-0} per unit volume of the water body [dissolved plus reactive particulate phase] by manual colorimetric analysis
	SDN:P01::**NTRIAAZX**	Concentration of nitrite {NO2- CAS 14797-65-0} per unit volume of the water body [unknown phase] by colorimetric autoanalysis

3. Technical note for determination of concentration of nitrate

The method was introduced by Morris and Riley (1963)[149], but only later was the dynamics of the involved reactions studied in depth (Nydhal, 1976[150]; Grasshoff, 1983[151]). The method for the determination of nitrate (NO_3^-) is based on its reduction to nitrite, which is then determined colorimetrically via the formation of an azo dye. It had proved to be reliable and useful for work at sea and is widely free from interferences in nearshore and oceanic waters.

The method determines the sum of nitrite and nitrate; therefore, a separate determination of nitrite must be conducted, and concentration subtracted from that obtained with this method. At concentration levels higher than about 20 μmol L^{-1}, calibration curves for a low and high range must be established.

Nitrate is reduced to nitrite in a reduction column filled with copper-coated cadmium granules. The yield of the reduction depends on the pH of the solution and on the activity of the metal surface. The conditions of the reduction described in the method are adjusted to a pH of about 8.5, so that nitrate is converted to nitrite almost quantitatively (90-95 %) and not reduced further. Ammonium chloride

[149] Morris A.W., Riley J.P. (1963) The determination of nitrate in sea water. Analytica Chim. Acta, 29, 272-279.
[150] Nydhal F. (1976) On the optimum conditions for the reduction of nitrate to nitrite by cadmium. Talanta, 23, 349-357.
[151] Grasshoff K. (1983) Determination of nitrate. In: "Methods of Seawater Analysis", Grasshoff K., M. Ehrhardt, K. Kremling Eds, Verlag Chemie, Weinheim, 143-150.

buffer is used to control the pH and to complex the liberated cadmium ions. The nitrite formed is then determined colorimetrically (at 540 nm). The proposed method is substantially that illustrated by Grasshoff (1983).

Under this Technical Note related to determination of concentration of nitrate, this Monitoring Guidelines provides the following IMAP Protocols for the colorimetric determination of concentration of nitrate:

- Protocol for manual colorimetric determination of concentration of nitrate;
- Protocol for automated colorimetric determination of concentration of nitrate.

3.1 Protocol for manual colorimetric determination of concentration of nitrate

a. Equipment:

The equipment for manual colorimetric determination of concentration of nitrate include:

1. graduated cylinders or 50 mL pipettes
2. 100 mL borosilicate glass containers (beaker)
3. laboratory glassware for chemical preparations
4. 1 mL automatic dispenser
5. 1000 mL and 500 mL volumetric flasks
6. volumetric flasks of 100 mL class A
7. 1 L class A volumetric flask
8. precision micropipettes to measure volumes in the range of 10-100 µL
9. analytical scale
10. stove
11. microwave oven
12. dryer
13. spectrophotometer or colorimeter sensitive to 543 nm equipped with cells of at least 50 mm optical path
14. peristaltic pump with one or more channels
15. reduction columns
16. 4-4.5 mm internal diameter tygon tube
17. glass wool
18. pH meter
19. 0.25- and 0.42-mm mesh sieves for particle size (60 and 40 mesh)

b. Chemical products:

The chemical products for manual colorimetric determination of concentration of nitrate include:

1. sulfocromic mixture
2. concentrated hydrochloric acid [HCl]
3. sulfanilamide [$NH_2SO_2C_6H_4NH_2$]
4. *N*-(1-Naphthyl) ethylenediamine dihydrochloride [$C_{10}H_7NHCH_2CH_2NH_2 \cdot 2HCl$]
5. potassium nitrate 99.999% [KNO_3]
6. sodium nitrate [$NaNO_2$]
7. ammonium chloride [NH_4CI]
8. ammonium hydroxide [NH_4OH]
9. granular cadmium for reactors [Cd]
10. copper sulphate pentahydrate [$CuSO_4 \cdot 5H_20$]
11. chloroform [$CHCl_3$]

c. *Preparation of stock solutions:*

Sulfanilamide reagent

50 mL of concentrated hydrochloric acid is poured into a beaker of at least 600 mL, containing 400 mL of reagent grade water, and stirred until completely mixed. 5 g of sulfanilamide in this solution are dissolved. The volume with reagent grade water is adjusted to 500 ml. The solution is stable for many months if stored in plastic or glass containers, in the refrigerator.

NNEDDC reagent

500 mg of *N*-(1-Naphthyl)ethylenediamine dihydrochloride in 450 mL of reagent grade water is dissolved and adjusted to volume with reagent grade water in a 500 mL flask. The solution stored in the refrigerator, in dark bottles, is stable for 1-2 months and must be discarded if brown colour is developed.

Copper sulphate solution

20 g of copper sulphate pentahydrate in reagent grade water in a 1 L volumetric flask are dissolved and stored in a dark bottle. The solution is stable indefinitely.

Hydrochloric acid about 0.2 mol L^{-1}

100 mL of concentrated hydrochloric acid and 500 mL of reagent grade water are mixed in a beaker while stirring. The solution is stable indefinitely stored in a glass bottle.

Ammonium-ammonium chloride buffer

10 g of ammonium chloride for analysis in 1 L of reagent grade water in a beaker are dissolved. The pH of the solution is adjusted to 8.5 adding, drop by drop while stirring and checking the pH with a pH meter, a small quantity of ammonium hydroxide solution (about 1.5 mL should be sufficient). The buffer solution must be stored in a dark bottle and is stable for many months.

Standard solution of potassium nitrate 5 mmol L^{-1}

Few grams of potassium nitrate in an oven at 110 °C are dried and cooled in a silica gel dryer. 505.6 mg are weighted on an analytical balance, and in 800 mL of reagent grade water in a 1 L (class A) flask dissolved and adjusted to volume. The solution should be kept refrigerated, in a dark bottle, adding a few drops of chloroform and is stable for about a month.

Standard solution of sodium nitrite e 2 mmol L^{-1}

Few grams of sodium nitrite in an oven at 110 °C are dried and cooled in a silica gel dryer. 138 mg are weighted on an analytical balance, and in 800 mL of reagent grade water in a 1 L (class A) flask dissolved and adjusted to volume. The solution should be kept refrigerated, in a dark bottle, adding a few drops of chloroform and is stable for about a month.

d. *Preparation of specific equipment for analysis:*

d.1. Maintenance of reaction vessels

The reaction flasks with boiling sulfochromic mixture are periodically washed, rinsed abundantly with reagent grade water and them dried. For ordinary maintenance, after use, are rinsed with reagent grade water and placed upside down on filter paper.

d.2. Reduction column

The major part of the reduction column is made of a U-shaped glass tube with a total length of about 10-25 cm and an inner diameter of 3 mm. Connections to the 100 ml sample bottle and the 25 ml (marked) Erlenmeyer flask are made from flexible capillary tubing (Tygon). The sample is drawn through the column by a small peristaltic pump. For practical purpose, the whole set-up can be mounted in a box. Suitable flow rates should be determined by experimentation.

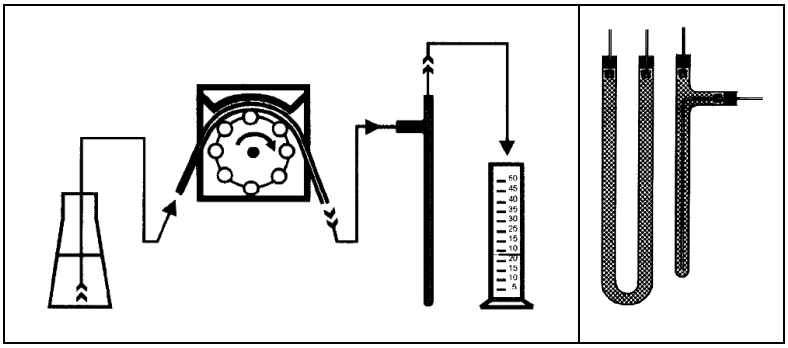

Figure 2. Reduction column for the analysis of nitrate and type of columns.

d.3. Preparation of the reduction column

Commercially available granulated cadmium (e.g. coarse powder for reductors grade - BDH) is sieved and the fraction between 40 and 60 mesh (i.e. around 0.25 and 0.42 mm) is retained and used.

The sieved cadmium granules are freed from oxides by washing them in 0.2 mol L^{-1} hydrochloric acid. The granules in a 200 mL beaker vigorously (for about 3 minutes) with 100 mL of the copper sulphate solution are shaken. Afterwards, the copperized cadmium granules under gentle shaking are rinsed, the water decanted and washed again until the water is free from finely dispersed copper.

Cadmium is poisonous. It should, therefore, be handled with great care. The dust is never inhaled and all operations on the dry metal are perform in a fume hood.

The copperized granules are poured into the reduction column (with the aid of distilled water and a funnel). The effective packing is encouraged by gently tapping the column with a pencil. When one arm is filled, the funnel is connected to the other arm and the procedure repeated. Some space in both side arms is leaved in order to pack in some glass wool.

The Cd is activated by passing through about 250 mL of buffer solution (ammonium chloride) containing about 100 µmol L^{-1} nitrate and rinsed thoroughly with buffer solution before the reducer is used for analysis.

The reduction efficiency of the reduction column is checked by analysing a nitrate standard solution of suitable concentration (e.g. equimolar). The determined absorbance is compared with that of a nitrite solution of the same concentration (e.g. if $A_{NO3} = 0.200$, $A_{NO2} = 0.210$, the reduction efficiency would be (0.200 x 100) / 0.210 = 95.2%).

The column is ready for use and is stable for a few months.

e. Analytical procedure:

e.1. Reagents to be prepared at the time of use

Preparation of standard solutions

5 standards of known nitrate concentration are prepared: by diluting, in 100 mL flasks (class A), respectively 10, 25, 50, 75, 100 µL of standard solution of potassium nitrate (measured with a precision pipette) with oligotrophic seawater or reagent grade water. The concentrations of nitrate are thus between 0.5 and 5 µmol L^{-1} plus the nitrate content of oligotrophic seawater, if used for dilution.

3 standards of known nitrite concentration are prepared: by diluting, in 100 mL flasks (class A), respectively 50, 75, 100 µL of standard solution of sodium nitrite (measured with a precision pipette) with oligotrophic seawater or reagent grade water. The concentrations of nitrate are thus between 1 and 2 µmol L^{-1} plus the nitrite content of oligotrophic seawater, if used for dilution.

e.2. Analytical treatment

At the time of analysis, if the sample had been frozen, possibly using a 37 °C bath or in a microwave oven is quickly thawed;

The 100 mL beakers with 50 mL of sample or each of the standards (measured with a graduated cylinder) are filled.

50 mL of ammonium buffer (measured with a graduated cylinder) are added and mixed well.

The end of the capillary tube is inserted in the beaker containing the first sample to be analyzed.

The peristaltic pump is adjusted in such a way to ensure a flow rate between 2.5- and 3-mL min^{-1} and started allowing the sample to pass through the reduction column. The first 25 mL of sample is discarded.

The next 25 mL is collected and transferred in a 50 mL flask or beaker.

The other samples to be analysed, the nitrate standards and the nitrite standards is passed through the system, interrupting the operation of the peristaltic pump between each operation

After passing the last sample, the reduction column is washed with 50 mL of ammonium buffer and always kept completely full of buffer.

With a graduated cylinder for of each of the nitrite standards a substandard is prepared: 12.5 mL of standard and 12.5 mL of ammonium buffer is added to a beaker and properly mixed. The preparation of these standards, which have not passed through the reduction column, is necessary to verify the degree of transformation of nitrite to compounds with a lower oxidation number, independently of the degree of efficiency of the column, except for impurities of nitrate present in the nitrite standard.

1 mL of sulfanilamide reagent to each flask containing the samples and the three series of standards (nitrates, nitrites and nitrites not passed through the reduction column) with a dispenser are added and the reaction allowed to take place for 5 minutes.

1 mL of NNEDDC reagent to each sample or standard with a dispenser are added and the reaction allowed to take place for 10 minutes.

e.3. Preparation of reagent blanks

At least two replicates of reagent blanks in the same type of 100 mL borosilicate glass container, using 50 mL of reagent grade water are prepared applying the same procedure as for samples and standards, including the passage through the reduction column.

e.4. Spectrophotometric measurements

The absorbance of the blank ($bl_{c,\,i}$) of each cell of the spectrophotometer or colorimeter, used for reading against the reference cell, at 543 nm is measured, both filled with water without regents. The operation is superfluous if only one cell is used.

For each flask, the number of the cell used, the identification of the contents of the flask (sample, standard solution, blank) are noted in a form. The cell is rinsed with part of its contents, filled and the absorbance at 543 nm read, recording the reading on the same form.

The reading of the blanks is affected by a small error due to the different matrix used, but it is usually negligible as it is related only to the nitrate impurities in the ammonium buffer.

f. <u>Calculations</u>

The reagent blank (bl) as the average of the two blank readings is calculated.

The correlation between the absorbance values of the three series of standards and the assumed concentrations, using the Ordinary Least-Squares Regression is calculated. The colorimetric factor for the nitrates (f_1), for the nitrites (f_2) and for the nitrites not passed on the reduction column (f_3) is represented by the slopes.

The efficiency of the column for the reduction of nitrate and for the preservation of the nitrite present in the sample is indicated by the ratios f_1/f_2 and f_2/f_3. If the reduction efficiency is unsatisfactory (<90%), the length of the column must be increased, while this must be decreased if the nitrite yield is less than 95%.

The concentration of nitrate in the samples is calculated with the following equation:

$$c(NO_3^-) / \mu mol\ L^{-1} = (ABS - bl - bl_{c,\,i}) - c(NO_2^-) / f_2) \cdot f_1$$

where

$c(NO_3^-)$ = concentration of nitrate

$c(NO_2^-)$ = concentration of nitrite in the sample (independently derived)

ABS = absorbance of the sample

bl = blank of the reagents

$bl_{c,\,i}$ = blank of the i-th cell used

f1 = colorimetric factor of nitrate

f2 = colorimetric factor of nitrite

For a cell with a 50 mm optical path, the colorimetric factor of nitrate is equal to about 8.0 µmol L^{-1}, i.e. a difference in concentration of 2 µmol L^{-1} (for example between standard solution 1 and 3) should be the difference in absorbance of about 0.25.

g. Important notes

Before carrying out the analysis, the characteristics of the column must be carefully checked. If air bubbles enter the column, it is preferable to empty them and repack, as the retention time becomes variable following the progressive expulsion of air. Alternatively, the buffer solution can be allowed to pass through the column for about 20-30 minutes, to expel most of the air. In both cases it is necessary to pass through the column at least a series of standards to verify any variations in the yield of the reduction.

The determination of the factor f_2 is superfluous when the nitrite concentrations turn out to be of an order of magnitude lower than those of nitrates. In this case it is enough to calculate the colorimetric factor f_1 and subtract the nitrite concentration from the values obtained.

If a large number of samples are to be analysed, the efficiency of the reduction column during the analysis must be checked periodically.

h. Possible problems

The suggested method is trouble- and interference-free. However, Hydrogen sulphide, hardly present in samples containing nitrate, can be precipitated as copper or cadmium sulphide (Grasshoff, 1983).

The efficiency of the column can be reduced if concentrations of phosphates higher than 2 µmol L^{-1} are present (Olsen, 1980)[152].

[152] Olsen R.J. (1980) Phosphate interference in the cadmium reduction analysis of nitrate. Limnol. Oceanogr., 25, 758-760.

3.2 Protocol for automated colorimetric determination of concentration of nitrate

a. Reagents

Buffer

10 g of ammonium chloride dissolved in 700 mL of DDW, and then brought to the volume of one liter must be prepared. To the solution must be added 1 mL of Brij and sodium hydroxide in a percentage such as to bring the pH of the solution to a value of 8.5. The solution is very stable.

Sulfanilamide

10 g of sulfanilamide in 100 mL of concentrated HCl are dissolved and adjusted to 1 L with DDW. The solution should be stored in a brown glass bottle and is stable for at least one month.

Ethylenediamine dihydrochloride

1 g of Ethylenediamine dihydrochloride is dissolved in 1 L of DDW. The solution should be stored in a dark glass bottle and is stable for at least one month.

b. Standard

51. Few grams of potassium nitrate in an oven at 110 °C are dried and cooled in a silica gel dryer. 505.6 mg are weighted on an analytical balance, and in 800 mL of DDW in a 1 L (class A) flask dissolved and adjusted to volume. The solution should be kept refrigerated, in a dark bottle, adding a few drops of chloroform and is stable for about a month. This standard is used in the daily procedure for the preparation of 5 lower concentration standards.

The concentration of the minor standards is chosen based on the amount of NO_3^- salts expected to be found, so that the set of sub-standards covers the entire range of expected concentrations. From the 5 standards a multiplication factor is obtained which is necessary to calculate the concentrations.

c. Reducer

The reducer is composed of a 20 cm long Pyrex glass tube with an internal diameter of 2 mm and U-bent.

Cadmium granules previously prepared according to the procedure described below are inserted into the tube.

Some granular cadmium are sieved to obtain a fraction of granules between 0.42 and 0.60 mm, then washed with 10% HCl and with DDW at the end. 2 g of copper sulphate are dissolved in 100 mL of DDW. The cadmium is immersed in the solution and shaken until the colour disappears. The cadmium is washed until the total elimination of colloidal copper bound to cadmium, silvery colour of the grains. The glass tube is filed with DDW and the granules inserted from the flask with a Pasteur pipette. Once the reducer has been filled, glass wool at the ends is inserted, to prevent cadmium to escape.

There are alternatives to the use of granular cadmium such as the use of cadmium coils or with internal walls covered with cadmium or the use of polyethylene coils with a cadmium wire inside. In all cases, the activation of cadmium with the copper sulphate solution is necessary in some procedures, copper sulphate is added continuously with the buffer.

d. Manifold

The manifold (Figure 3) is built of three injectors and five coils, one with 5 turns and four with 10 turns, and a reducer. The first injector (A) is equipped with three inputs: the first is for the sample, the second is for air bubbles and with the third input the first reagent is introduced. Immediately after, a coil made up of 5 turns in which the liquid is mixed with the buffer, is located. At the end of the coil a de-bubbler, which has the function of eliminating the bubble from the circuit to prevent air from entering the reducer that is connected to the bubbler itself at point (B), is present. At point (C) after the reducer, the second injector equipped with three inputs can be found: The first for the sample to be

reduced from NO_3^- to NO_2^-, the second to restore the air bubbles and with the third the second reagent is introduced. Immediately after 4 coils made up of 10 coils each can be found: in the first 2 the mixing with the second reagent takes place, in the other 2 is where the third reagent at point (D) is injected.

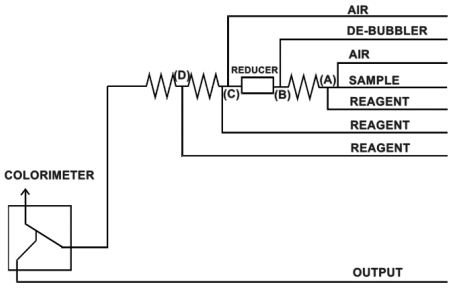

Figure 3. Manifold for nitrate measurement.

e. <u>Important notes</u>

Air passage through the reducer is not allowed.

The efficiency of the reducer is checked by comparing the nitrate standard with that of the nitrites according to the next methodology: 1) Two nitrate standards are prepared: one at a concentration of 5 µmol L^{-1}, the other at 10 µmol L^{-1}. The doubling of the concentration must correspond to an effective doubling of the reading. 2) Two nitrate standards of the same concentration of 5 µmol L^{-1} are prepared. The two standards are run in the same circuit prepared for nitrates and that they give the same reading value must be checked; to ensure that there has not been a reduction in the concentration of nitrites in the cadmium column.

The air bubbles point of the circuit must be adjusted each time the reducer is replaced by acting on the flow rates of the pipes.

The reducer by passing a standard of NO_3^- with a concentration of 25 µmol dm-3 through the circuit each time it is replaced must be activated.

If an unstable baseline is observed when the appliance is turned on in the absence of reagents, the circuit with 10% HCl must be washed.

If during the analysis an evident increase in the baseline is observed, the colorimeter reading cell by injecting 50% hydrochloric acid directly into the cell without stopping the circuit must be immediately cleaned.

The DDW is deionized if possible, directly in the water container of the instrument.

If a change of components of the circuit (injectors, bubblers) is necessary, the circuit by changing the flow rates of the pipes must be rebalanced.

Suitable containers for the different reagents must be used. The cap of the container must be provided with small holes in which to insert capillaries (needles, etc.) for the withdrawal of the reagent.

When mixed standards are used, NO_3^- standards with either NH_4^+ or NO_2^- standards never must be combined.

Water poor in nutrients, or oligotrophic water (OSW), as washing water between one sample and another must be used. OSW with salinity values similar to the sample to be analysed must be used.

The NO_2^- standard, passed through the nitrate reduction column must have the same reading value as the NO_2^- standard analysed in the nitrite circuit.

Since the concentration of nitrates is determined after their reduction to nitrites: The copper cadmium does not have a reduction efficiency of 100% and in certain conditions it also reduces nitrite. Therefore, if it were necessary to discriminate the two ions, the efficiency of the reducer should be accurately determined both for nitrite with a solution with a concentration of nitrite only and for nitrate with a solution with a known concentration of nitrate only.

For the parameter described in this protocol, the symbol and unit suggested by the International System of Units (SI), as well as the expected accuracy, along with the Method identifiers as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Symbol: $c(NO_3^-)$	**Unit:** μmol L^{-1}	
Precision: ±0.02	**Accuracy:** ± 0.02	**LOD:** 0.03
Method identifier:	SDN:P01::**NTRAMADZ**	Concentration of nitrate {NO3- CAS 14797-55-8} per unit volume of the water body [dissolved plus reactive particulate <unknown phase] by filtration and manual colorimetric analysis and correction for nitrite
	SDN:P01::**CHEMM012**	Concentration of nitrate {NO3- CAS 14797-55-8} per unit volume of the water body [dissolved plus reactive particulate phase] by colorimetric autoanalysis and correction for nitrite

4 Technical note for determination of concentration of ammonium

The determination of concentration of ammonium is based on a series of photochemically catalysed reactions that lead to the formation of indophenol blue. The concentration of the compound is then measured colorimetrically. The first analytical application of the formation of indophenol from phenol and hypochlorite was performed by Berthelot (1859)[153].

The formation of monochloramine predominates, compared to that of di- and trichloramine, for pH values higher than 7.5. The next stage of the reaction consists in the attack of monochloramine on the benzene ring of the phenol to form, probably, chloraminoquinone. Finally, quinone, or in any case the intermediate formed, produces indophenol by copulation with another phenol. This stage is strictly pH dependent, as OH^- enters directly into the reaction. For this reason, all methods that use phenol and hypochlorite require an environment with a pH of around 10.5 (Ivancic and Degobbis, 1984)[154].

Finally, given the importance of pH control in the development of the reaction (Sasaki and Sawada, 1980)[155], the significant salt effect (different yield of the reaction in fresh or salt water) that occurs in this method (Koroleff, 1983)[156] largely depends on the buffer capacity of the sample matrix. For this reason, the method can be applied to samples collected in estuarine environments, where the variations in alkalinity are strong, by adequately buffering the solution (Mantoura and Woodward, 1983)[157].

The procedure outlined here, mainly follows the methods described by Grasshoff and Johansen (1973)[158] and by Koroleff (1983) as described by Hansen and Koroleff (1999)[159] and is adapted to this manual from the previous one (UNEP/MAP/MED POL, 2005).

Under this Technical Note for determination of concentration of ammonium, this Monitoring Guidelines provides the following IMAP Protocols for the colorimetric determination of concentration of ammonium:

- Protocol for manual colorimetric determination of concentration of ammonium;
- Protocol for automated colorimetric determination of concentration of ammonium.

4.1 Protocol for manual colorimetric determination of concentration of ammonium

a. Equipment:

The equipment for manual colorimetric determination of concentration of nitrate include:

1. graduated cylinders or 50 mL pipettes
2. 100 mL borosilicate glass containers (beaker)
3. laboratory glassware for chemical preparations
4. 1 mL automatic dispenser
5. 1000 mL and 500 mL volumetric flasks
6. volumetric flasks of 100 mL class A
7. 1 L class A volumetric flask
8. precision micropipettes to measure volumes in the range of 10-100 µL
9. analytical scale
10. stove
11. microwave oven
12. dryer
13. spectrophotometer or colorimeter sensitive to 543 nm equipped with cells of at least 50 mm optical path, preferable 100 mm

b. Chemical products:

1. The chemical products for manual colorimetric determination of concentration of nitrate include:sulfocromic mixture
2. concentrated hydrochloric acid [HCl]
3. Sodium hydroxide [NaOH]
4. Potassium persulfate [$K_2S_2O_8$]
5. phenol [C_6H_5OH]
6. disodium EDTA [$C_{10}H_{14}N_2Na_2O_8$]
7. sodium dichloroisocyanuric acid [$C_3HCl_2N_3NaO_3$]
8. sodium nitroprusside dihydrate [$Na_2Fe(CN)_5NO \cdot 2H_2O$]
9. trisodium citrate dihydrate [$C_6H_5Na_3O_7 \cdot 2H_2O$]
10. ammonium chloride [NH_4CI]
11. ammonium hydroxide [NH_4OH]
12. chloroform [$CHCl_3$]

c. Preparation of stock solutions:

"Ammonia-free" water

There is no standard procedure for the preparation of water with very low ammonia content. De-ionized water may sometimes be used without subsequent distillation, but it must be noticed that ion exchange resins potentially bleed out organic substances and ammonia. In case the ammonia blank concentrations are higher than 0.3 µmol L^{-1}., the water should be subjected to subsequent distillation. In this second step, 0.3 g NaOH and 1 g $K_2S_2O_8$ are added to 1000 mL of water (in a 2 L flask). The solution should be boiled for 10 minutes to remove ammonia (without the condenser) and then distilled until a residue of about 150 mL. The distilled water should be stored in a tightly sealed container, preferably made of glass. The method of preparation of ammonia-free water should be regularly checked and appropriate blanks must be analysed with every batch of samples. As an alternative, "open sea surface water" can be used as "ammonia-free" water.

Buffer solution

240 g trisodium citrate dihydrate ($C_6H_5Na_3O_7 \cdot 2H_2O$), 20 g of disodium EDTA ($C_{10}H_{14}N_2Na_2O_8$) and 0.4 g NaOH in about 600 ml distilled water are dissolved. The solution is boiled (to remove ammonia) until the volume is below 500 mL. It is then cooled and diluted to 500 mL with "ammonia-free" water. The solution is stable and should be stored in a well-stoppered polyethylene bottle.

Phenol reagent

80 g colourless phenol (C_6H_5OH) is dissolved in 300 mL of ethanol, added 600 mL of distilled water and 600 mg of sodium nitroprusside dihydrate ($Na_2Fe(CN)_5NO \cdot 2H_2O$) in "ammonia-free" water and diluted to 1000 ml. When stored in a tightly closed dark bottle and in a refrigerator, the solution should be stable for several months. **Phenol is a particularly toxic compound and safety glasses and gloves should be worn and all handling conducted in a fume cupboard.**

Hypochlorite reagent

1 g of sodium dichloroisocyanuric acid ($C_3HCl_2N_3NaO_3$; dichloro-s-triazine-2, 3, 6 (1H, 3H, 5H)-trione) and 8 g NaOH in "ammonia-free" water are dissolved and diluted to 500 mL. The sodium dichloroisocyanuric acid is employed as a hypochlorite donor (in comparison to generally used commercial hypochlorite solutions) has the advantage of being a stable solid, and that it is easy to prepare. The solution should be stored in a dark bottle in a refrigerator and is stable for at least a week.

Ammonia stock solution (A) (10 mmol L^{-1} NH3)

Ammonium chloride (NH_4Cl) is dried at 100 ºC to constant weight. Then dissolve 0.0535 g NH4Cl in "ammonia-free" water and dilute to 100 mL in a volumetric flask. When kept in a glass bottle (protected from sunlight) and in a refrigerator, the solution should be stable for at least several weeks.

Ammonia working solution (B) (100 µmol L^{-1} NH3)

Exactly 10.0 ml of the stock solution is diluted with "ammonia-free" water to a final volume of 1000 ml in a volumetric flask made of glass.

d. Preparation of specific equipment for analysis:

d.1. Treatment of reaction vessels

All flasks and tubes to be used should be cleaned with hot HCl, rinsed well with "ammonia-free" water and kept closed between analyses. The analysis should be performed in a well-ventilated room with no ammoniacal solutions stored (**Note:** this should include any cleaning agents containing ammonia and used by laboratory cleaning staff during or outside normal working hours). This includes the NH_4Cl reagent used for nitrate analysis. **Smoking should be forbidden.**

Alternative: Before use, all flasks should be treated by performing the reaction in them with the addition of chemical reagents to the "ammonia-free water" or "open sea surface water". The reaction should proceed at least for 6 hours and the flasks should be shaken time to time during the reaction period. Later, the flask should be rinsed with ammonia-free water and kept stoppered when not in use. The flasks should not be washed between the analysis of different sets of samples/standards, but just rinsed with "ammonia-free" water and kept closed.

e. Analytical procedure:

e.1. Reagents to be prepared at the time of use

Preparation of standard solutions

7 standards of known ammonia concentration are prepared: by diluting, in 100 mL flasks (class A), respectively 0.5, 1, 2, 3, 5, 7 and 10 mL of Ammonia working solution (B) (measured with a precision pipette) with "ammonia-free" water or "open sea surface water" and filled to the 100 mL mark. The concentrations of ammonia are thus between 0.5 and 10 µmol L^{-1}. In this instance, it is probably best not to use low nutrient seawater unless it is known to have a suitably low ammonia concentration.

e.2.Analytical treatment

At the time of analysis, if the sample had been frozen, possibly using a 37 °C bath or a microwave oven is quickly thawed.

The flasks with an aliquot of samples or standard solutions of different concentrations are pre-rinsed.

The flasks with 50 mL of sample or each of the standard (measured with a graduated cylinder) are filled.

2 ml phenol reagent, 1 ml buffer solution and 2 ml hypochlorite reagent are added. The solution is mixed by swirling between the additions. The reaction bottles are closed properly and kept in a dark place during the reaction time which is at least 6 hours at room temperature, but which is reduced to 30 minutes if the samples are incubated in a water bath at 37 ºC ± 1 ºC. Note that standards and samples of the same series must be treated simultaneously, and in the same way.

e.3. Preparation of reagent blanks

One 100 mL flask is filled with 50 mL and one with 47,5 mL of distilled water or "open sea surface water"

To the first 2 ml phenol reagent, 1 ml buffer solution and 2 ml hypochlorite reagent are added and to the other 3 ml phenol reagent, 1.5 ml buffer solution and 3 ml hypochlorite reagent. The solutions are mixed by swirling between the additions. The reaction bottles are closed properly and kept in a dark place during the reaction time as for samples and standards.

e.4. Spectrophotometric measurements

The absorbance of the blank ($bl_{c,\,i}$) of each cell of the spectrophotometer or colorimeter, used for reading against the reference cell, at 630 nm is measured, both filled with water without regents. The operation is superfluous if only one cell is used.

For each flask, the number of the cell used, the identification of the contents of the flask (sample, standard, blank) are noted in a form. The cell is rinsed with part of its contents, filled and the absorbance at 630 nm read, recording the reading on the same form.

f. Calculations:

The reagent blank (bl) as the average difference between the values of the two blanks is calculated.

The correlation between the absorbance values of the 7 standards and the assumed concentrations, using the Ordinary Least-Squares Regression is calculated. The colorimetric factor (f) is represented by the slope, covering a concentration range 0.5 to 10 µmol L^{-1}.

The concentration of ammonia in the samples is calculated with the following equation:

$$c(NH_4) / \mu mol\ L^{-1} = (ABS - bl - bl_{c,\,i})\ f$$

where

$c(NH_4)$ = concentration of ammonia

ABS = absorbance of the sample

bl = blank of the reagents

$bl_{c,\,i}$ = blank of the i-th cell used

f = colorimetric factor

As already mentioned, for any given concentration of ammonium the blue color produced in seawater is less intensive than in distilled water. Thus, for each sample a correction must be made with respect to its salinity and the resulting pH. In many circumstances a simple correction (Hansen and Koroleff, 1999) may be used where the correction is given by:

$$c(NH_4)_{corr} / \mu mol\ L^{-1} = [1 + 0.0073\ S_s]\ c(NH_4)_{uncorr}$$

where

S_s = salinity of the sample.

g. Important notes:

The method is very sensitive to the effects of a possible contamination of the glassware or reagents; therefore, it is recommended to strictly follow the instructions given for washing the glassware and to use the recommended chemical products.

It is essential to ensure that the work environment is smoke-free and that there are no reactants in the vicinity that can release ammonia.

h. Possible problems:

Interferences from amino acids and urea (at seawater levels) can be neglected but may be significant in estuarine or brackish waters, especially where these are contaminated with urban waste.

Hydrogen sulphide can be tolerated up to about 60 µmol L^{-1}. Samples with higher H_2S concentrations should be diluted.

The blue colour of the indophenol, however, is influenced by salinity, which must be compensated by the application of a salt factor (see above).

4.2 Protocol for automated colorimetric determination of concentration of ammonium

a. Reagents

Buffer

The buffer is composed of 120 g of trisodiocitrate, dissolved in 500 mL DDW, and adjusted to 1L. Sodium hydroxide must be added to this solution in a percentage such as to bring the pH of the solution to a value of 11. This reagent must be stored in a glass bottle and is very stable.

Phenol reagent

35 g of phenol and 0.40 g of sodium dichloroisocyanuric acid are dissolve in 800 mL of DDW and adjusted to 1000 mL. This reagent is stable for 24 hours.

Hypochlorite reagent

5 g of sodium hydroxide and 1 g of dichloroisocyanurate are dissolved in 400 mL of DDW and adjusted to 500 mL. This reagent must be stored in a glass bottle at a temperature of + 4 °C and is stable for a week.

b. Standards

About 2 g of ammonium chloride is dried in an oven at a temperature of 100 °C to constant weight and then placed in a silica gel dryer for another 24 hours. The ammonium chloride is dissolved in DDW in such a proportion as to obtain a concentration of 2 mmol L^{-1}. This standard is used in the daily procedure for the preparation of 5 lower concentration standards.

The concentration of the minor standards is chosen based on the amount of NH_4^+ salts that are expected to be found, so that the set of sub-standards covers the entire range of expected concentrations. From the 5 standards a multiplication factor is obtained which is necessary to calculate the concentrations.

c. Manifold

The manifold (Fig. 4) is built of three injectors, three coils of 10 turns each, a thermostatic bath and a trap containing 10% hydrochloric acid. The first injector (A) is equipped with 3 inputs: the first is for the sample, the second for air bubbles, by which the liquid is divided into many equal segments and with the third input the first reagent is introduced. Immediately after, there are 2 coils made up of 10 coils each: in the first the liquid is mixed with the buffer; in the second at point (B) the second reagent is injected. At point (C) the third reagent is injected. To accelerate the blue production of indophenol, the solution is passed through a coil immersed in a thermostated bath (D) at a temperature of 75 °C. At the exit of the bath, at point (E) the solution is cooled passing through the last coil. The air for producing the air bubbles is introduced into the circuit through a trap (F) containing 10% HCl. This measure must be adopted to ensure that any ammonia vapours contained in the laboratory air are eliminated

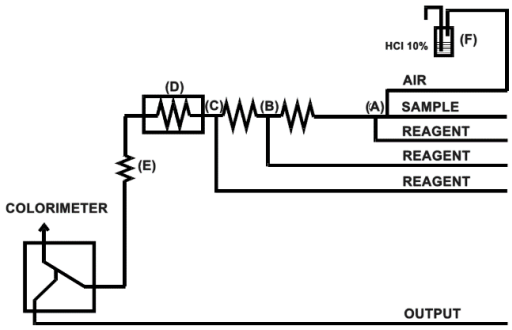

Figure 4. Manifold for ammonium measurement.

a. Important notes

The base line must be stable and if any fluctuations as if even small variations are noted it would mean that flocculate has formed in the sample caused by the phenol that is no longer stable:

The reagents one at a time, in strict order from the first to the third mast be inserted;

The circuit must be washed with the progressive elimination of the reagents from the third to the first;

If precipitate is observed to form near the hypochlorite injector the circuit is probably dirty or the buffer inefficient;

If an unstable baseline is observed when the appliance is turned on in the absence of reagents, the circuit with 10% HCl must be washed;

If during the analysis an evident increase in the baseline is observed, the colorimeter reading cell by injecting 50% hydrochloric acid directly into the cell without stopping the circuit must be immediately cleaned;

The DDW is deionized if possible, directly in the water container of the instrument;

If the ambient temperature is higher than + 20 °C a heat sink to the cooling coil must be installed;

If a change of components of the circuit (injectors, bubblers) is necessary, the circuit by changing the flow rates of the pipes must be rebalanced;

Suitable containers for the different reagents must be used. The cap of the container must be provided with small holes in which to insert capillaries (needles, etc.) for the withdrawal of the reagent;

When mixed standards are used, NO_3^- standards with either NH_4^+ or NO_2^- standards never must be combined;

Water poor in nutrients, or oligotrophic water (OSW), as washing water between one sample and another must be used. OSW with salinity values similar to the sample to be analysed must be used.

a. Symbol, units and precision

For the parameter described in this protocol, the symbol and unit suggested by the International System of Units (SI), as well as the expected accuracy, along with the Method identifiers as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Symbol: $c(NH_4^+)$	**Unit:** µmol L^{-1}	
Precision: ±0.02	**Accuracy:** ± 0.02	**LOD:** 0.03
Method identifier:	SDN:P01::**AMONMATX**	Concentration of ammonium {NH4+ CAS 14798-03-9} per unit volume of the water body [dissolved plus reactive particulate phase] by manual colorimetric analysis
	SDN:P01::**AMONAADZ**	Concentration of ammonium {NH4+ CAS 14798-03-9} per unit volume of the water body [dissolved plus reactive particulate <unknown phase] by filtration and colorimetric autoanalysis

Monitoring Guidelines/Protocols for Determination of Concentration of Key Nutrients in Seawater – Phosphorous and Silica Compounds

1. Introduction

1. In the Monitoring Guidelines for Key nutrients – Phosphorous and Silica compounds in Seawater, the protocols for manual and automated determination of the concentration of orthophosphate, orthosilicate, and total phosphorous and total nitrogen are elaborated. Probably the most important property of seawater in terms of its effect on life in the marine environment is the concentration of dissolved nutrients. The most critical of these nutrients are nitrogen and phosphorus because they play a major role in stimulating primary production by plankton. These elements are known as limiting because plants cannot grow without them. At the moment, the water classification scheme on which the assessment of GES regarding Ecological Objective 5 related to eutrophication is based on chlorophyll *a* concentration as presented in detail in the IMAP Guidance Factsheets (UNEP/MAP, 2019) [160] , although in near future it will be complemented by those based on concentration of key nutrients in seawater.

The IMAP Protocols elaborated within this Monitoring Guidelines for Determination of Concentration of Key Nutrients in Seawater – Phosphorous and Silica Compounds provides detail guidance on the necessary equipment, chemical reagents, analytical procedures along with appropriate methodologies for measurement of the concentration of nitrite, nitrate and ammonium in seawater, calculations, data transformation if necessary and identify weak points all endorsed through important notes and possible problems.. However, they are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories, which should be tested and accordingly modified, if need be, in order to validate their final results.

This Monitoring Guidelines build upon the UNEP/MAP Integrated Monitoring and Assessment Programme (IMAP) respectively IMAP Guidance Fact Sheets for IMAP Common Indicators 13 and 14 (UNEP/MAP, 2019); standardized protocols (UNEP/MAP, 2019a)[161] and Data Quality Assurance schemes (UNEP/MAP, 2019b)[162] in order to allow the comparability of the data and build of regional assessment schemes. They also take into account previous Sampling and Analysis Techniques for the Eutrophication Monitoring Strategy of MED POL (UNEP/MAP/MED POL, 2005)[163], however providing detail procedures that are of relevance for IMAP implementation. With the details of the protocols for determination of Key nutrients, the needs of the measurements both in off-shore areas and in narrow coastal areas are addressed.

In the Subchapters “Symbol, units and precision” at the end of each Protocol, for all parameters described in it, the symbol and unit suggested by the International System of Units (SI) are presented. The expected accuracy, precision and where possible the Limit of Detection (LOD) are also presented. A Method identifier is also presented as it is provided in the Library P01 of the British Oceanographic Data Centre (BODC) Parameter Usage Vocabulary respectively included in Data Dictionaries and Data Standards for eutrophication built in IMAP Pilot Info System.

The below flow diagram informs on the category of this Monitoring Guidelines related to determination of chlorophyll *a* in seawater within the structure of all Monitoring guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.

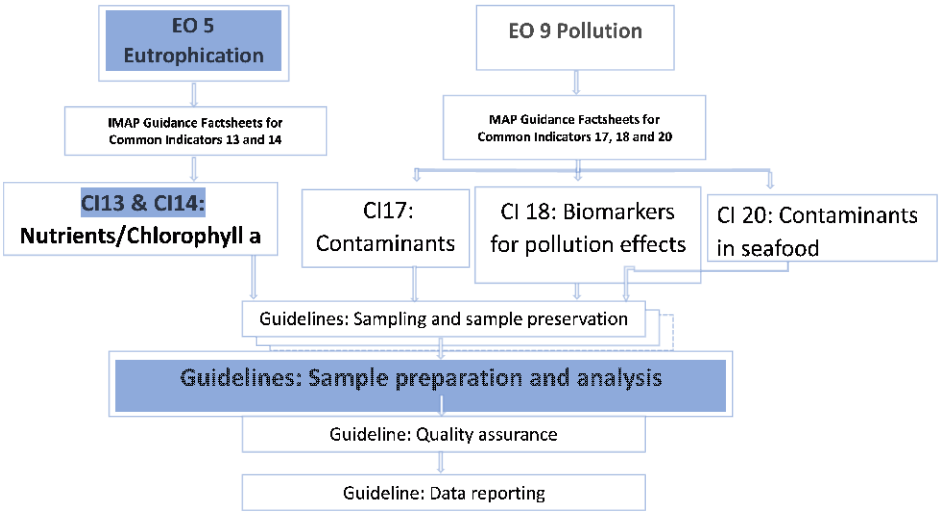
n. Continuous flow methods

The principle used by the continuous segmented-flow auto-analysers (SFA) is recognized as the most reliable and accurate method for determination of nutrients. Different systems are available and can be configured to meet the standard methods such as ISO, EPA, ASTM, etc… Wherever possible it is strongly recommended that such analysers are used because of the considerable increase in precision

[160] (UNEP/MAP, 2019), UNEP/MED WG.467/5. IMAP Guidance Factsheets: Update for Common Indicators 13, 14, 17, 18, 20 and 21: New proposal for candidate indicators 26 and 27.
[161] (UNEP/MAP, 2019a), UNEP/MED WG.463/6. Monitoring Protocols for IMAP Common Indicators related to pollution.
[162] (UNEP/MAP, 2019b), UNEP/MED WG.46710. Schemes for Quality Assurance and Control of Data related to Pollution
[163] (UNEP/MAP/MED POL), 2005. Sampling and Analysis Techniques for the Eutrophication Monitoring Strategy of MED POL. MAP Technical Reports Series No. 163. UNEP/MAP, Athens, 46 pp.

and sample throughput that they offer. Ideally such analysers can be used in laboratories on board a research vessel allowing problems of sample deterioration during storage to be circumvented.

The multiplicity of methods reported in the literature is more related to the optimization of methods for different environments that a significant difference in the reactions used. In the Protocols dedicated to the individual methods, some specific aspects will be mentioned. On the general principles of SFA systems, in addition to the documentation provided by the manufacturers to the classic textbooks of Strickland and Parsons (1965)[164] and Grasshoff et al. (1999)[165] can be referred. Equally numerous are the technical reports of the various laboratories produced to homogenize the methods within the programs international like JGOFS or WOCE. In the Protocols only the most essential indication on the most frequently used method will be provided. Important notes on the critical parts of the methods, for it successful performance will also be indicated.



Flow Diagram: Monitoring Guidelines for IMAP Ecological Objective 5 and 9.

2. Technical note for the determination of concentration of orthophosphate

The method is based on the formation of a blue phosphomolybdic complex (from the molybdenum blue group) whose concentration is measured by colorimetry (spectrophotometer or colorimeter) (Deniges, 1920)[166]. The aspects relevant to the development of the phosphomolybdic complex are summarized as follow: The molybdate ion and its polymers form, in an acid environment, stable heteropoly acids with elements of the IV and V groups (Boltz and Mellon 1947[167]). Phosphomolybdic acid is a yellow complex. The reduction of molybdate from Mo (VI) to Mo (V) in this complex produces a blue coloured heteropoly acid. The maximum absorbance peak varies according to the type of reducing agent used, probably in relation to the variation of the ratio between Mo (VI) and Mo (V) as a whole and to the type of aggregation of the basic units in the solution.

---

[167] Boltz D.F., Mellon M.G. (1947) Determination of phosphorus, germanium, silicon, and arsenic by the heteropolyblue method. Ind. Eng. Chem. Anal. Ed., 19, 873-877.

Murphy and Riley (1962)[168] introduced, in the procedure for the determination of phosphates in seawater, the use of a trivalent antimony salt, which enters the heteropoly acid in a ratio of about 1:1 with phosphorus. This modification induces a shift of the maximum absorbance towards the infrared, with an increase in the molar extinction coefficient and a drastic increase in the rate of formation. The subsequent reduction occurs by ascorbic acid, thus eliminating dependencies on ionic strength (saline effect) and on temperature (Murphy and Riley, 1958[169], 1962). To minimize the interference of other ions that react in a similar way with molybdates, it is necessary to keep the pH of the final solution below 1, a condition in which the formation of hetero-polyacids with Si and As is decidedly disadvantaged (Koroleff , 1983)[170].

The methodology of Murphy and Riley (1962) as reported by Strickland and Parsons (1968) is described in this note.

Under this Technical Note, this Monitoring Guidelines provides the following IMAP Protocols for the colorimetric determination of concentration of orthophosphate:

- Protocol for manual colorimetric determination of concentration of orthophosphate;
- Protocol for automated colorimetric determination of concentration of orthophosphate.

2.1 Protocol for manual colorimetric determination of concentration of orthophosphate

a. Equipment:

The equipment for manual colorimetric determination of concentration of orthophosphate include:

1. graduated cylinders or 50 mL pipettes
2. 100 mL borosilicate glass containers (preferably flasks with cap)
3. laboratory glassware for chemical preparations
4. 5 mL automatic dispenser
5. 50, 250- and 500-mL volumetric flasks
6. volumetric flasks of 100 mL class A
7. 1 L class A volumetric flask
8. precision micropipettes to measure volumes in the range of 10-100 µL
9. analytical scale
10. stove
11. microwave oven
12. dryer
13. spectrophotometer or colorimeter sensitive to 880 nm (as a fullback 705 nm) equipped with cells of at least 50 mm optical path

b. Chemical products:

The chemical products for manual colorimetric determination of concentration of orthophosphate include:

1. sulfocromic mixture
2. concentrated sulfuric acid [H_2SO_4]
3. ammonium heptamolybdate tetrahydrate [$(NH_4)\ 6Mo_7O_{24}\cdot 4H_2O$]
4. potassium antimony tartrate [$K(SbO)C_6H_4O_6$]
5. ascorbic acid [$C_6H_8O_6$]
6. potassium dihydrogen phosphate [KH_2PO_4]
7. chloroform [$CHCl_3$]

[168] Murphy J., Riley J.P. (1962) A modified single solution method for the determination of phosphate in natural waters. Analytica Chim. Acta, 27, 31-36.
[169] Murphy J., Riley J.P. (1958) A single-solution method for the determination of soluble phosphate in sea water. J. Mar. Biol. Ass. U.K., 37, 9-14.
[170] Koroleff F. (1983) Determination of phosphorus. In: "Methods of Seawater Analysis", Grasshoff K., M. Ehrhardt, K. Kremling Eds, Verlag Chemie, Weinheim, 125-139.

c. Preparation of stock solutions

5 N sulfuric acid

140 mL of concentrated sulfuric acid are poured slowly into a beaker containing about 800 mL of reagent grade water. Allow to cool and the volume is adjusted to 1 L. The solution, stored in a dark glass bottle, is stable indefinitely.

Molybdate ammonium solution

15 g of crystalline ammonium heptamolibdate tetrahydrate are dissolved in 450 mL of reagent grade water in a 500 mL flask and adjusted to volume. The solution, stored in a plastic or borosilicated glass bottle, away from direct light, is usable until a white precipitate is formed.

Solution of potassium antimony tartrate

0.34 g of potassium antimony tartrate are dissolved in 250 mL of reagent grade water in a 250 mL flask. The solution, stored in a glass or plastic bottle, is stable for many months, unless a white flocculate is formed.

Standard solution of potassium dihydrogen phosphate 2 mmol L^{-1}

Few grams of potassium dihydrogen phosphate in an oven at 110 °C are dried. 272.18 mg on an analytical balance are weighted and in 900 mL of reagent grade water in a 1 L (class A) flask dissolved. Up to volume is adjusted and a few drops of chloroform as a preservative added. The solution, stored in a borosilicate glass bottle, is stable for a few months.

d. Preparation of specific equipment for analysis

d.1. Treatment of reaction vessels

The reaction flasks with boiling sulfochromic mixture are periodically washed. Keep them tightly capped, filled with reagent grade water and mixed reagent (if necessary, the residue of the analysed sample can be left in the flask).

e. Analytical procedure

e.1. Reagents to be prepared at the time of use

Ascorbic acid solution

2.7 g of ascorbic acid is dissolved in 45 mL of reagent grade water in a 50 mL flask and to volume adjusted. The solution, stored in a plastic or glass bottle, is stable for 24 hours.

Mixed reagent

In a glass container are mixed: 100 mL of ammonium molybdate solution, 250 mL of 5 N sulfuric acid, 100 mL of ascorbic acid solution and 50 mL of potassium antimony tartrate solution. The solution is sufficient for about 100 samples but deteriorates within a few hours and must be replaced when its color changes from light yellow to very dark yellow.

Preparation of standard solutions

5 standards of known phosphate concentration are prepared: by diluting, in 100 mL flasks (class A), respectively 10, 25, 50, 75, 100 µL of standard solution of potassium dihydrogen phosphate (measured with a precision pipette) with oligotrophic seawater. The concentrations of phosphate are thus between 0.2 and 2 µmol L^{-1} plus the orthophosphate content of oligotrophic seawater.

e.2. Analytical treatment

At the time of analysis, if the sample had been frozen, possibly using a 37 °C bath or a microwave oven is quickly thawed;

The flasks with an aliquot of samples or standard solutions of different concentrations are pre-rinsed;

The flasks with 50 mL of sample or each of the standard solutions (measured with a graduated cylinder) are filled. Given the remarkably low concentrations of phosphates and the relative sensitivity of the analytical method, it is advisable to carry out at least two determinations for each sample to be analysed.

5 mL of mixed reagent to each sample or standard solution with a dispenser are added and shaken.

For the reaction to take place is necessary at least 5 minutes and no more than 2 hours.

e.3. Preparation of reagent blanks

Four 100 mL flasks are filled with 50 mL of oligotrophic seawater, low in phosphates, after rinsed with the same water.

5 mL of mixed reagent are added to two flasks and double the amount in the other two.

The time the reaction to take place is necessary as for samples and standard solutions.

e.4. Spectrophotometric measurements

The absorbance of the blank ($bl_{c,\,i}$) of each cell of the spectrophotometer or colorimeter, used for reading against the reference cell, at 882 nm is measured, both filled with water without regents. The operation is superfluous if only one cell is used.

For each flask, the number of the cell used, the identification of the contents of the flask (sample, standard solution, blank) are noted in a form. The cell is rinsed with part of its contents, filled and the absorbance at 882 nm read, recording the reading on the same form. Alternatively, with a loss of sensitivity of about 30%, the absorbance can be read at 705 nm.

f. Calculations:

The reagent blank (bl) as the average difference between the values of the blanks containing 10 mL and those containing 5 mL of mixed reagent is calculated.

The correlation between the absorbance values of the 5 standards and the assumed concentrations, using the Ordinary Least-Squares Regression is calculated. The colorimetric factor (f) is represented by the slope.

A standard with zero concentration of orthophosphates represented by the sample of oligotrophic seawater to which a single dose of mixed reagent has been added is considered. In this way, a total of 6 standards are obtained, covering a concentration range of 2.0 µmol L^{-1}.

The concentration of orthophosphate in the samples is calculated with the following equation:

$$c(PO_4) / \mu mol\ L^{-1} = (ABS - bl - bl_{c,\,i})\ f$$

where

$c(PO_4)$ = concentration of orthophosphates

ABS = absorbance of the sample

bl = blank of the reagents

$bl_{c,\,i}$ = blank of the i-th cell used

f = colorimetric factor

For a cell with a 50 mm optical path, the colorimetric factor is equal to about 9.9 µmol L^{-1}, i.e. a difference in concentration of 1 µmol L^{-1} (for example between standard solution 3 and 5) should be the difference in absorbance of about 0.1.

g. Important notes and possible problems:

The cells of the spectrophotometer (or colorimeter) should be washed periodically with a 5% solution of soda or hydrofluoric acid because the phosphomolybdic complex tends to stick to the walls, giving them a slight blue colour.

The samples should not be lived in plastic containers at room temperature for a long time. Both due to the bacterial activity that develops on the walls of the bottle and to adsorption phenomena the concentration of phosphates tends to decrease.

After thawing the samples, the analysis must be complete in a short time to avoid phenomena of hydrolysis of organic phosphates or polyphosphates.

If the standard solution has been stored in the refrigerator, it must be brought to laboratory temperature before starting the standardization procedure.

Spectrophotometer measurement mast be performed within two hours of adding the reagent to avoid the slow formation of silicomolybdic heteropoly acids.

Sulphides can interfere with the reaction, if present in concentrations higher than 50 µmol L^{-1} of S^{2-}, as the extinction coefficient and the maximum absorbance are altered (De Jonge and Villerius, 1980)[171]. In this case the sulphides from the sample should be removed (Airey et al., 1984)[172].

Silicates interfere if present at concentrations higher than 150 µmol L^{-1} as a complex that absorbs in the same band is developed (Koroleff, 1983).

The reagent blank, if prepared using distilled water, may have a higher optical density than the samples to be analysed. This can derive from different causes; it is advised the procedure indicated in the paragraph "Preparation of reagent blanks" to strictly be followed or the method suggested by Novoselov et al. (1976)[173] to be applied.

2.2 Protocol for automated colorimetric determination of concentration of orthophosphate

a. Reagents:

Ammonium molybdate

10 g of molybdate are dissolved in 800 mL of DDW. The solution is stable for at least one month.

Antimony potassium tartrate (KAT)

2.5 g of KAT is dissolved in 800 mL of DDW and adjusted to 1 L. The solution is stored in a glass bottle and is stable for at least one month.

b. Solutions for use

Mixed reagent

In a 250 mL graduated glass cylinder and shaking after each addition are mixed: 100 mL of molybdate stock + 25 mL of KAT + 30 mL of H_2SO_4 conc. + 1 mL of SLS (Sodium-Laurel-Sulphate) and adjusted to 250 ml. The reagent is very stable and should be stored in a glass bottle.

Ascorbic acid

---

[171] De Jonge V.N., Villerius L.A. (1980) Interference of sulphide in inorganic phosphate determination in natural waters. Mar. Chem., 9, 191-197.

[172] Airey D., Dal Pont G., Sandars G. (1984) A method of determining and removing sulphide to allow the determination of sulphate, phosphate, nitrite and ammonia by conventional methods in small volumes of anoxic waters. Analytica Chim. Acta, 166, 79-92.

[173] Novoselov A.A., Sheremet'Yeva A.I., Danilenko A.F. (1976) Method for simultaneous obtaining silicon-free and phosphate-free sea water aboard ship. Oceanology, 16, 358-359.

1.8 g of ascorbic acid is dissolved in 100 mL of DDW.

c. Standards:

About 2 g of KH_2PO_4 are dried in an oven at a temperature of 110 °C, checking for constant weight of the salt over time. The salts are then placed in a silica gel dryer for another 24 hours. It is then dissolved in reagent grade water in such a proportion to obtain a concentration of 2 mmol L^{-1}.

This standard is used in the daily procedure for the preparation of 5 lower concentration standards. The concentration of the minor standards is chosen based on the amount of PO_4^{3-} salts expected to be found, so that the set of sub-standards covers the entire range of expected concentrations. From the 5 standards a multiplication factor is obtained which is necessary to calculate the concentrations.

d. Manifold

The manifold (Fig. 1) is composed of two injectors and four coils of 10 turns each. The first injector (A) is equipped with 3 inputs: the first is for the sample, the second is for the air and the third input provided for the introduction of the first reagent. Immediately after there are 3 composite coils with 10 coils each: in the first 2 the first reagent is mixed, in the other 2 the second reagent is introduced at point (B), by means of the second injector.

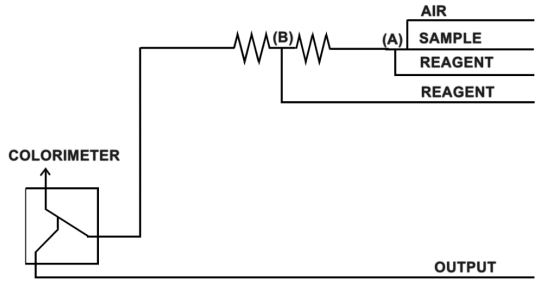

Figure 1. Manifold for orthophosphate measurement.

e. Calculations

The calculations are performed as is generally indicated in the Annex I: Automated methods for determination of concentration of key nutrients in seawater – Calculation of the concentration.

f. Important notes and possible problems

If an unstable base line occurs when the appliance is turned on in the absence of reagents, wash the circuit with NaOH and then with 10% HCl.

If during the analysis there is an evident increase in the baseline, the colorimeter reading cell is immediately cleaned by injecting 50% hydrochloric acid directly into the cell without stopping the circuit.

DDW is deionized if possible, in the water container of the instrument.

If change of components of the circuit (injectors, bubblers) is necessary, the circuit by changing the flow rates of the pipes must be rebalance

Suitable containers for the different reagents must be used. The cap of the container must be provided with small holes in which to insert capillaries (needles, etc.) for the withdrawal of the reagent.

Water poor in nutrients, or oligotrophic sea water (OSW), as washing water between one sample and another must be used. OSW must have salinity values similar to the sample to be analysed.

At temperatures below 10 °C a thermostated bath at a temperature of 40 °C must be added to the manifold.

If precipitate forms in the molybdate the reagent must be discarded.

In case of preparation of mixed standards of PO_4 and SiO_4 the standards must never be prepared in the same flask.

A colorimeter with a very narrow entrance of the reading cell to avoid refractive disturbances must be used.

High sensitivity reading phototubes for 880 nm readings must be used.

a. Symbol, units and precision

Symbol: $c(PO_4^{3-})$	**Unit:** µmol L^{-1}	
Precision: ±0.02	**Accuracy:** ± 0.02	**LOD:** 0.03

	SDN:P01::**PHOSAAZX**	Concentration of phosphate {PO43- CAS 14265-44-2} per unit volume of the water body [unknown phase] by colorimetric autoanalysis

3 Technical note for the determination of concentration of orthosilicate

The determination of the dissolved silicates is carried out by inducing the formation of a silicomolibdic polyacid which is subsequently reduced to molybdenum blue. The final compound has a maximum absorbance at 810 nm, and is measured by colorimetry.

The chain of reactions is strongly influenced by even minimal variations in the reaction conditions due to the multiplicity of intermediate products and their instability. Silicomolybdic acid is formed with different speed in relation to the degree of polymerization of the silicate.

Silicomolybdic acid exists in at least two isomers α and β (Strickland, 1952[174]; Morrison and Wilson, 1963[175]; Truesdale and Smith, 1975[176]), of which the former is thermodynamically more stable but kinetically disadvantaged at pH values below 2. The two isomers α and β of silicomolybdic acid have a peak of maximum absorbance in the blue part of the spectrum, but with quite different extinction coefficients, none of which are particularly high. Furthermore, for the reasons mentioned above, they do not guarantee sufficient stability over time. The subsequent reduction of isomer β by p-methylaminophenol (metol) sulphate in an acid environment and in the presence of sulphite produces a stable molybdenum blue for at least 2 hours from the completion of the reaction (Mullin and Riley, 1955)[177]. Also, in this process it is important to control the pH to avoid a direct reduction of excess molybdenum by metol.

All the reactions outlined above depend both on the ionic strength of the solution and on the presence of specific ions, especially the divalent ones; therefore, the concentration of the final product and perhaps also its molar extinction depend on the salt concentration of the reaction mixture and, consequently, of the sample. The formation of polyacids with molybdate, in fact, is also characteristic

of other ions, in particular phosphate and arsenate (Boltz and Mellon, 1947); to avoid the interference of the phosphomolybdates, these can be eliminated with oxalic acid (Strickland and Parsons, 1968).

Under this Technical Note, this Monitoring Guidelines provides the following IMAP Protocols for the colorimetric determination of concentration of orthosilicate:

- Protocol for manual colorimetric determination of concentration of orthosilicate;
- Protocol for automated colorimetric determination of concentration of orthosilicate.

3.1 Protocol for manual colorimetric determination of concentration of orthosilicate

a. Equipment

The equipment for manual colorimetric determination of concentration of orthosilicate include:

1. 25 mL cylinder or pipette, preferably in plastic
2. 50 mL plastic containers (preferably flasks or bottles with polyethylene or polymethylpentene cap)
3. laboratory glassware for chemical preparations
4. automatic dispensers or pipettes of 10 and 15 mL
5. Whatman paper filters n. 1
6. 500 mL volumetric flasks
7. volumetric flasks of 100 mL class A
8. 1 L class A volumetric flask
9. precision micropipettes to measure volumes in the range of 10 - 100 µL
10. spectrophotometer or colorimeter sensitive to 810 nm, which has cells of at least 50 mm optical path
11. platinum crucible
12. agitator
13. analytical scale
14. stove
15. dryer

b. Chemical products

The chemical products for manual colorimetric determination of concentration of orthosilicate include:

1. sulfocromic mixture
2. concentrated sulfuric acid [H_2SO_4]
3. concentrated hydrochloric acid [HCl]
4. ammonium heptamolybdate tetrahydrate [$(NH_4)_6Mo_7O_{24}\cdot 4H_2O$]
5. oxalic acid [$C_2H_2O_4\cdot 2H_2O$]
6. 4-methylaminophenol sulfate (metol) [$(CH_3NHC_6H_4OH)\cdot 2H_2SO_4$]
7. anhydrous sodium sulphite [Na2SO_3]
8. powdered silica [SiO_2] and anhydrous sodium carbonate [Na_2CO_3] (alternatively, sodium hexafluorosilicate [Na_2SiF_6])

c. Preparation of stock solutions

Molybdate reagent

4.0 g of ammonium heptamolybdate tetrahydrate (preferably crystalline) are dissolved in about 300 mL of reagent grade water. 12 mL of concentrated hydrochloric acid are diluted in 100 -150 mL of reagent grade water and mixed well. While stirring, the molybdate solution is added in that of hydrochloric acid and adjusted to 500 mL with reagent grade water. The solution, stored in a polyethylene bottle, away from direct light, is usable until a white precipitate is formed or turned blue.

Solution of metol and sulphite

6 g of anhydrous sodium sulphite are dissolved in 400 mL of reagent grade water and 10 g of metol added, while stirring until it is completely dissolved. The solution is filtered, on a Whatman No. 1 filter, previously rinsed with reagent grade water, and and adjusted to 500 mL. The solution is stored in a tightly closed borosilicate glass bottle and therefore should not be stored for more than a month.

Oxalic acid solution

A saturated solution of oxalic acid by dissolving 50 g of acid in 400 mL of reagent grade water is prepared. The solution is decanted separating it from the residual crystals and adjusted to the volume of 500 mL. The solution is stored in a polyethylene bottle and stable indefinitely.

50% (v / v) sulfuric acid solution

250 mL of concentrated sulfuric acid are poured into 250 mL of reagent grade water while stirring. Cool to room temperature and make up to volume with reagent grade water in a 500 cm3 mat. The solution, stored in a container of dark plastic, is stable indefinitely.

Standard solution of silicate (10 mmol L^{-1})

The pure silica is heated to 1000 °C, cooled in a desiccator and checked for constant weight with repeated weighing. 601.0 mg of silica (the theoretical amount corresponding to 10 mmol of Si) are weighted in a platinum crucible and 1.5 g of anhydrous sodium carbonate added. Everything is mixed with a metal spatula and melted, until completely homogenized, at a temperature of 1000 °C. The melted product is kept at 1000 °C until clear. Then is cooled and in several portions of very hot water dissolved and transferred after cooling to a 1 L flask (class A). Adjusted to volume with reagent grade water and quickly transferred to a high-density polyethylene bottle. The solution is stable for a few months.

Alternatively, sodium hexafluorosilicate can be used. It must be dried in an oven at 105 °C for one hour in a metallic melting pot. In this case, given the low solubility, it is preferable to prepare solutions with concentrations not exceeding 2 mmol L^{-1}, therefore the dilutions must be corrected proportionally. Since the product is not yet supplied in analytical purity, the quantity to be weighed must be calculated based on the purity indications of the supplier. The sodium hexafluorosilicate is dissolved in 700 mL of reagent grade water in a plastic container, under gentle heating, and the solution into a 1 L (class A) flask transferred. The dissolution time is correlated to the crystalline form of the product and few hours may be necessary. The volume is adjusted to 1 L and quickly transferred to a plastic bottle to prevent the fluoride from removing silicon from the glass. The solution is stable for few months.

d. Preparation of specific equipment for analysis:

d.1. Treatment of reaction vessels

Wash the 50 cm3 polyethylene or polymethylpentene containers with sulphochromic mixture, rinse them thoroughly with reagent grade water and dry them. For routine maintenance it is sufficient, after use, to rinse them with reagent grade water and place them upside down on filter paper.

e. Analytical procedure:

e.1.Reagents to be prepared at the time of use

Reducing reagent

100 mL of metol and sulphite solution and 60 mL of oxalic acid solution are mixed. Slowly 60 mL of 50% sulfuric acid are added and adjusted to 300 mL in a cylinder with reagent grade water. This reagent must be prepared immediately before use.

e.2. Preparation of standard solutions

5 solutions of known concentration of silicate by diluting, in 100 mL flasks (class A), respectively 10, 25, 50, 75, 100 µL of standard silicate solution (measured with a precision micropipette) with oligotrophic sea water are prepared, resulting in concentrations between 1 and 10 µmol L^{-1} of silicate, plus the silicate content of the oligotrophic water.

e.3. Analytical treatment

At the time of analysis, the sample, if had been frozen, is thawed slowly keeping it away from light. The analysis must be performed after 12 hours, to allow the polymeric forms of silicates to depolymerize.

10 mL of molybdic reagent is poured (using a dispenser) into the container and while stirring 25 mL of sample or of each of the standard solutions (measured with a graduated cylinder) added.

Respecting the same times for all samples and calibration standards the reaction is allowed to take place for at least 15 minutes but not more than 30 minutes.

Using a dispenser, 15 mL of reducing reagent are added and allowed the reaction to take place for at least 1 hour. For the whole group of samples the same reaction times must be respected.

e.4. Preparation of reagent blanks

At least two replicates of reagent blanks in 50 mL polyethylene containers, using 25 mL of oligotrophic seawater must be prepared and treated with the same analytical procedure applied to the samples and standards.

In some cases, due to a high concentration of silicates in the oligotrophic sea water too high blank value may be observed. In that case it is advisable to remove them (Novoselov et al., 1976) or the blanks must be prepared with reagent grade water.

e.5. Spectrophotometric measurement

The absorbance of the blank ($bl_{c,\,i}$) of each cell of the spectrophotometer or colorimeter, used for reading against the reference cell, at 810 nm is measured, both filled with water without regents. The operation is superfluous if only one cell is used.

For each flask, the number of the cell used, the identification of the contents of the flask (sample, standard solution, blank) are noted in a form. The cell is rinsed with part of its contents, filled and the absorbance at 810 nm read, recording the reading on the same form.

f. Calculations

The reagent blank (bl) as the average difference between the values of the two blank readings is calculated.

The correlation between the absorbance values of the 5 standards and the assumed concentrations, using the Ordinary Least-Squares Regression is calculated. The color-metric factor (f) is represented by the slope.

The concentration of orthosilicate in the samples is calculated with the following equation:

$$c(SiO_4) \,/\, \mu mol\ L^{-1} = (ABS - bl - bl_{c,\,i}) \cdot f$$

where

$c(SiO_4)$ = concentration of orthosilicates

ABS = absorbance of the sample

bl = blank of the reagents

$bl_{c,\,i}$ = blank of the i-th cell used

f = colorimetric factor

For a cell with a 50 mm optical path, the colorimetric factor is equal to about 19 µmol L^{-1}, i.e. a difference in concentration of 10 µmol L^{-1} (such as for example between the water used to dilute the standard solutions and the standard 5) should be approximately 0.52 in the case of samples with salinity of 37.

g. Important notes and possible problems

As already mentioned, after thawing, the sample must be kept in dark for at least 12 hours at room temperature to favour the depolymerization of the silicates. In fact, polymerization is promoted by freezing and an underestimation of the concentration of reactive silicates will be observed (Burton and Leatherland, 1970[178]; MacDonald and McLaughlin, 1982[179]; MacDonald et al., 1986[180]).

The sample must be added to the molybdic reagent, and not vice versa, in order to guarantee a correct pH value.

During the analysis, all the samples must be kept at the same temperature, possibly around 20 °C, to avoid a variability depending on the thermal coefficient of the reaction.

Calibration standards using seawater with salinity equal to that of the samples must be prepared. If working in an estuarial environment, a set of standards that cover the range of salinity values found in the samples must be prepared. The saline coefficient (ratio between the colorimetric factor value in reagent grade water and in salt water) is quite variable: for water with salinity around 35 a value of about 0.85 is observed (Bien, 1958[181]; Fanning and Pilson, 1973[182]; Koroleff, 1983).

An abnormal yield of the reaction is related almost always to pH values different from 2 or on bad handling. The pH in the final mix must be between 1.8 and 2.2. Sometimes a bad mixing of the reaction mixture, as well as an incorrect pH value is responsible for the formation of a blue colour due to the direct reduction of the molybdate and not to that of the polyacids.

The suggested method is generally free from interference for sea water. However, interference of cations such as copper, iron, cobalt and nickel with the colour of their ions may be observed. In this case the absorbance of the sample at the same wavelength without adding the reagents is necessary to be measured and the value of this reading must be added to the reagent blank. If iron ions are present, which form ferric molybdate during the reaction, a hydroxylamine hydrochloride solution (Mullin and Riley, 1955) must also be added to the samples before analysis. The development of colour is not observed if the sulphides are present in a concentration below 5 mg L^{-1}, otherwise they must be oxidized with bromine water (Koroleff, 1983).

3.2 Protocol for automated colorimetric determination of concentration of orthosilicate

a. Reagents

Stannous chloride.

---

[179] MacDonald R.W., McLaughlin F.A. (1982) The effect of storage by freezing on dissolved inorganic phosphate, nitrate and reactive silicate for samples from coastal and estuarine waters. Water Res., 16, 95-104.

[180] MacDonald R.W., McLaughlin F.A., Wong C.S. (1986) The storage of reactive silicate samples by freezing. Limnol. Oceanogr., 31, 1139-1142.

[181] Bien G.S. (1958) Salt effect correction in determining soluble silica in sea water silicomolybdic acid method. Anal. Chem., 30, 1525-1526.

[182] Fanning K.A., Pilson M.E.Q. (1973) On the spectrophotometric determination of dissolved silica in natural waters. Anal. Chem., 45, 136-140.

20 g of stannous chloride are dissolved in 12.5 mL of concentrated HCl + 27.5 mL of DDW. The reagent is dissolved at a temperature of 70 °C.

Tartaric acid

100 g of tartaric acid are dissolved in 1 L of DDW.

Ammonium molybdate

40 g of molybdate are dissolved in 800 mL of DDW and then adjusted to l L.

b. Solutions for use

Molybdate

50 mL of 10% HCl + 40 mL of molybdate + 15 mL of DDW are mixed.

Stannous chloride

2.5 mL of stannous chloride + 48 mL of 10% HCl + 50 mL of DDW are mixed.

c. Standard

About 2 g of Na_2SiF_6 are dried in an oven at a temperature of 105 °C until a constant weight over time is reached. The salt is placed in a silica gel desiccator for another 24 hours. Then the salt is dissolved in reagent grade water in such a proportion to obtain a concentration of 10 mmol L^{-1}.

This standard is used in the daily procedure for the preparation of 5 lower concentration standards. The concentration of the sub-standards is chosen based on the amount of SiO_4 that is expected to be found, in a way the entire range of expected concentrations are covered. The multiplication factor for the calculation of concentrations is obtained from the 5 standards.

d. Manifold

The manifold (Fig. 2) is composed of three injectors and six coils of 10 turns each. The first injector (A) is equipped with 3 inputs: The first for the sample, the second for air bubbles and the third where the first reagent is introduced. Immediately after 6 coils made up of 10 coils each can be found: in the first two the first reagent is mixed, in the second two where at point (B) the second reagent is injected, and finally in the last two where at point (C) the third reagent is injected.

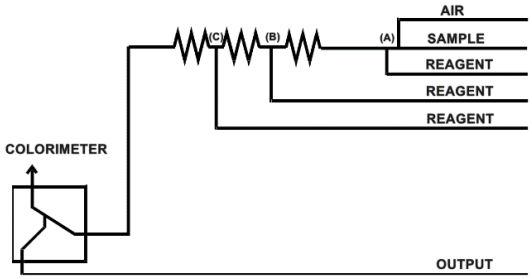

Figure 2. Manifold for orthosilicate measurement.

e. Calculations

The calculations are performed as is generally indicated in the Annex I: Automated methods for determination of concentration of key nutrients in seawater – Calculation of the concentration.

f. Important notes and possible problems

If an unstable base line occurs when the appliance is turned on in the absence of reagents, wash the circuit with NaOH and then with 10% HCl.

If during the analysis there is an evident increase in the baseline, the colorimeter reading cell is immediately cleaned by injecting 50% hydrochloric acid directly into the cell without stopping the circuit.

DDW is deionized if possible, in the water container of the instrument.

If change of components of the circuit (injectors, bubblers) is necessary, the circuit by changing the flow rates of the pipes must be rebalance

Suitable containers for the different reagents must be used. The cap of the container must be provided with small holes in which to insert capillaries (needles, etc.) for the withdrawal of the reagent.

Water poor in nutrients, or oligotrophic sea water (OSW), as washing water between one sample and another must be used. OSW must have salinity values similar to the sample to be analysed.

If precipitate forms in the molybdate the reagent must be discarded.

In case of preparation of mixed standards of PO_4 and SiO_4 the standards must never be prepared in the same flask.

A colorimeter with a very narrow entrance of the reading cell to avoid refractive disturbances must be used.

High sensitivity reading phototubes for 820 nm readings must be used.

If, when inserting the reagents, a blue colour is noticed in the sample, at the exit from the second series of coils, this would indicate that the tartaric acid is to be discarded.

Symbol, units and precision

4 Technical note for the combined determination of concentration of total nitrogen and total phosphorous

The concentration of total nitrogen or phosphorus in a water sample is represented as the sum of the moles of the element in question present in the form of organic and inorganic, dissolved and particulate species. In this analytical procedure both elements are determined after oxidation and hydrolysis of most of the compounds initially present in the sample in the same reaction mixture, with the production of nitrate and orthophosphate respectively. The procedure for the common mineralization of the two elements are presented.

The oxidizing agent used is potassium persulfate $K_2S_2O_8$, which decomposes when hot according to the reaction:

$$K_2S_2O_8 + H_2O \rightarrow 2KHSO_4 + 1/2O_2$$

During the oxidation reaction, H + is produced which determines a pH variation. The behaviour of the various nitrogen compounds in the oxidation reaction is different. Those containing N-N bonds are oxidized more difficultly while those with N = N bonds are rather refractory to nitrate oxidation. Furthermore, a time of at least 30 minutes is necessary to ensure the complete disappearance of the persulfate from the oxidation solution, thus preventing possible interference in the subsequent phases of the analytical assay, especially for the determination of nitrate.

The appearance in the reaction mixture, even in an alkaline environment, of Cl_2 which would interfere with the subsequent reduction of nitrates by cadmium is due to the subtraction of OH- by magnesium in the form of a precipitate, which does not readily neutralize the H^+ ion produced by the reaction (Nydhal, 1978)[183]. Therefore, adding OH^- to the reaction mixture or shaking the reaction vessels is suggested. Koroleff (1968[184]; 1983) on the other hand argued that in an alkaline environment, while the complete hydrolysis of the bound phosphorus into organic compounds is achieved, a yield of polyphosphates decomposition around 60% is observed. However, the concentration of the latter is generally of secondary importance compared to bound phosphorus in organic compounds, for which Koroleff (1968; 1983b[185]) and Valderrama (1981)[186] believe that a unique method for the determination of nitrogen and total phosphorus in seawater are equally reliable.

In the method reported by Valderrama (1981), thanks to the use of a buffer based on the boric acid-borate couple and based on the reactions involved, the pH of the mixture starts from about 9.7 and reaches the end of the process at about 4-5, thus creating the appropriate conditions for the oxidation-hydrolysis of both nitrogen and phosphorus and the necessary decomposition of excess persulphate. The method presented is the method of Valderrama (1981) in the version of Koroleff (1983a, b).

Under this Technical Note, this Monitoring Guidelines provides the following IMAP Protocols for the combined colorimetric determination of concentration of total nitrogen and total phosphorous:

- Protocol for preparation of samples for a combined determination of concentration of total nitrogen and total phosphorus;
- Protocol for combined manual colorimetric determination of concentration of total nitrogen and total phosphorous;
- Protocol for combined manual colorimetric determination of concentration of total nitrogen and total phosphorous.

4.1 Protocol for preparation of samples for a combined determination of concentration of total nitrogen and total phosphorus

h. Equipment

The equipment for preparation of samples for determination of concentration of total nitrogen and total phosphorous include:

1. graduated cylinders of 50 mL
2. 100 mL borosilicate glass, polypropylene, TPX or Teflon containers with hermetically sealed screw cap fitted with flange or Teflon gasket. It is recommended to use polyethylene bottles if the samples will be frozen.

i. Chemical products

The chemical products for preparation of samples for determination of concentration of total nitrogen and total phosphorous include:

1. potassium persulfate [K_2S_2O8] (nitrogen content <0.001%)
2. sodium hydroxide [NaOH] (nitrogen content <0.001%)

j. Preparation of reagents:

---

[183] Nydahl F. (1978) On the peroxidisulphate oxidation of total nitrogen in waters to nitrate. Talanta, 12, 1123-1130.
[184] Koroleff F. (1968) Determination of total phosphorus in natural waters by means of persulphate oxidation. ICES C.M./C, 33, 209-212.
[185] Koroleff, F. (1983b) Total and organic nitrogen. In: "Methods of Seawater Analysis", Grasshoff K., M. Ehrhardt, K. Kremlin Eds, Verlag Chemie, Weinheim, 162-173.
[186] Valderrama J.C. (1981) The simultaneous analysis of total nitrogen and total phosphorus in natural waters. Mar. Chem., 10, 109-122.

Oxidizing solution

50 g of potassium persulfate (low N content) and 30 g of boric acid are dissolved in 1 L of sodium hydroxide 0.375 mol L^{-1} (15 g of NaOH are dissolved and diluted to 1 L with distilled water and stored in a polyethylene bottle). The reagent, if stored in a well capped polyethylene bottle and wrapped in aluminium foil, is stable for at least one week.

k. Sampling procedure

Using a 50 mL cylinder, rinsed at least twice with the sample, 50 mL of water for each sub-sample are poured directly from the sampling bottle into the reaction containers, which have also been previously rinsed with the sample.

If the sample is particularly turbid (frequent occurrence in coastal waters), a duplicate sampling is necessary to determine the turbidity.

As in all determinations that include particulate matter, sub-samples must be taken after having carefully shaken the sampling bottle or within very short times that prevent significant sedimentation of the particulate.

l. Sample storage

As regards conservation, one of the three methods indicated below can be used, which ensure acceptable results:

1. The samples are kept, at the time of collection, in the hermetically sealed reaction containers. The analysis can also be performed after a long period of time. In fact, following the oxidation reaction, the nitrates and phosphates produced remain constant.
2. Immediately after sampling, 5 mL of oxidizing solution are added and the sample containers hermetically sealed. Under these conditions the samples are stable for at least 48 hours. If the oxidation reaction takes place within this time, the nitrates and phosphates produced remain constant even for 2 ÷ 3 months (Nydhal, 1978).
3. The samples, in a polyethylene bottle, are quickly frozen, without filtering.

4.2 Protocol for combined manual colorimetric determination of concentration of total nitrogen and total phosphorous

a. Equipment

The equipment for combined manual colorimetric determination of concentration of total nitrogen and total phosphorous include:

1. all that indicated for nitrate and orthophosphate determination
2. autoclave or normal pressure cooker (in the latter case it may be more practical to use, as sample containers, test tubes of about 50 mL with screw caps and Teflon seals and use a small volume)

b. Chemical product

The chemical products for combined manual colorimetric determination of concentration of total nitrogen and total phosphorous include:

1. all that indicated for nitrate and orthophosphate determination
2. disodium EDTA [$C_{10}H_{14}N_2Na_2O_8$]

c. Preparation of stock solutions

For the ***determination of total nitrogen***, the stock solutions indicated in the Protocol for determination of nitrates and an organic nitrogen solution must be prepared.

Organic nitrogen solution (10 mmol L^{-1})

186.2 mg of disodium-EDTA are dissolved in 90 mL of reagent grade water, adjusted to100 mL in a volumetric flask (100 mL, class A) and stored in the refrigerator in a dark glass bottle. The solution is stable for a few months.

For the ***determination of total phosphorus***, the solutions listed below must be prepared:

Sulfuric acid (4.5 mol L^{-1})

250 mL of concentrated sulfuric acid to 750 mL of reagent grade water are carefully added, allowed to cool and adjusted to 1 L. Stored in a reagent bottle, the solution is stable indefinitely.

Mixed reagent

12.5 g of crystalline ammonium heptamolybdate tetrahydrate are dissolved in 125 mL of reagent grade water. 0.5 g of potassium antimony tartrate in 20 mL of reagent grade water are dissolved separately. The molybdate solution, while stirring, is added to 350 mL of 4.5 mol L^{-1} sulfuric acid, then the potassium antimony tartrate solution is added and mixed. The solution is preserved in a dark glass bottle and stable for several months.

d. Analytical procedure

d.1. Reagents to be prepared at the time of use

Acidified solution of ascorbic acid

10 g of ascorbic acid are dissolved in 50 mL of reagent grade water and 50 mL of 4.5 mol L-1 sulfuric acid added. The solution is stored in a dark glass bottle in the refrigerator. The solution can be used as long as it remains colorless (about a week), but is preferable to be prepared at the time of use.

d.2. Preparation of standard solutions

The Protocol for determination of concentrations of nitrate and orthophosphate must be followed.

d.3. Preparation of the solution for checking the efficiency of the oxidizing reagent

10 µmol L^{-1} solution of nitrogen

In a 100 mL flask (class A) 100 µL (measured with a precision pipette) of organic nitrogen stock solution is diluted with reagent grade water. The solution is divided into two 50 mL subsamples and 5 mL of oxidizing reagent added. The entire amount of nitrogen present in the solution (10 µmol L^{-1}) must be determined. If this does not happen, the oxidizing solution must be prepared again.

d.4. Preparation of reagent blanks

50 mL of reagent grade water are transferred into 3 reaction vessels and each inoculated with 5 mL of oxidizing reagent.

The prepared blanks are autoclaved following the procedure indicated for the analytical treatment of the samples.

To prepare the blanks of the reagents related to the analysis of total nitrogen (blN):

5 mL from each of the 3 containers are sampled with an automatic pipette and transferred into 100 mL beakers; 45 mL of reagent grade water are added to each;

To the blanks of the nitrogen reagents the same procedure applied to the samples and illustrated in detail in the Protocol for manual colorimetric determination of nitrate (ammonium buffer, reduction column, sulphanilamide, NNEDDC, spectrophotometric assay) is applied.

To prepare the blanks of the reagents related to the analysis of total phosphorus (blP):

To each of the 50 mL left in the 3 containers as indicated for the analytical treatment of the samples the reagents (acidified solution of ascorbic acid and mixed reagent) are added.

The spectrophotometric measurement as indicated in the Protocol for manual colorimetric determination of orthophosphate are performed.

d.5. Analytical treatment

The containers with the samples and the solutions to be analysed are put in an autoclave or pressure cooker and autoclaved/cooked for at least 30 minutes at 120 °C.

The containers are brought to room temperature and checked that the sample volume has remained unchanged. If necessary, the volume is adjusted back to 55 mL with reagent grade water, but the change in volume which may have led to a parallel contamination of the sample recorded.

At the end of the oxidation stage, all the nitrogen in the sample should have been converted to nitrate and all the phosphorus to phosphate.

The procedures as indicated in the Protocols for the determination of nitrate and phosphate are followed, considering the following additions and modifications.

For nitrogen analysis

5 mL from each of the samples and of the two control samples with EDTA are sampled with an automatic pipette and transferred into 100 mL beakers; 45 mL of reagent grade water are added to each.

The same procedure illustrated in detail in the Protocol for manual colorimetric determination of nitrate (ammonium buffer, reduction column, sulphanilamide, NNEDDC, spectrophotometric assay) is applied.

For phosphorus analysis

The remaining 50 mL of sample are used and 1 mL of acidified solution of ascorbic acid with is added with a dispenser;

The solution is shaken and after about 30 seconds 1 mL of mixed reagent (measured with a dispenser) is added while shaking;

The same procedure illustrated in detail in the Protocol for manual colorimetric determination of orthophosphate is applied for the spectrophotometric measurement.

e. Calculations

The blanks of the of the cells ($bl_{c,i,N}$ and $bl_{c,i,P}$) are calculated as indicated in the Protocols for manual colorimetric determination of nitrate and orthophosphates.

The blank of the reagents (oxidizing reagent plus colour development reagent), both for phosphate (bl_P) and for nitrate (bl_N) are calculated as the average of the absorbance values of the three solutions with reagent grade water.

The colorimetric factor for the two components are calculated according to the procedure indicated in the Protocols for manual colorimetric determination of nitrate (f_N) and orthophosphate (f_P).

The concentrations are calculated according to the equations:

$$c(\mathrm{TN}) / \mu\mathrm{mol\ L^{-1}} = (ABS_N - bl_N - bl_{c,i,N}) \cdot f_N$$

$$c(\mathrm{TP}) / \mu\mathrm{mol\ L^{-1}} = (ABS_P - bl_P - bl_{c,i,P}) \cdot f_P$$

where:

ABS_N = absorbance of sample at 553 nm
ABS_P = absorbance of sample at 882 nm
$bl_{c,i,N}$ = blank of i-th cell at 553 nm
$bl_{c,i,P}$ = blank of i-th cell at 882 nm
bl_N = blank of nitrogen reagents
bl_P = blank of phosphorus reagents
f_N = colorimetric factor for nitrate

f_P = colorimetric factor for phosphate

f. Important notes and possible problems

The containers should be rinsed with reagent grade water for at least a couple of times. Between the determinations the containers should be kept filled with an HCl solution of approximately 0.1 mol L^{-1}.

The test solution should not be used to correct the reaction yield, but only as a rough check of the oxidation efficiency, since a reduced oxidizing power can occur in relation to the different type of nitrogen compounds involved in the reaction.

About the determination of nitrogen, it should be noted that some problems may be due to impurities of the reactants. It is important to use low nitrogen persulfate or to follow the recrystallization technique reported in Nydhal (1978). It is also important to always check the quality of the reagent grade water being used. In fact, ammonia is almost always present in closed environments and dissolves easily in water, water as soon as it comes out of the purifier must be used, even if this does not eliminate the risk of substances released by the exchange resins.

4.3 Protocol for the combined automated colorimetric determination of concentration of total nitrogen and total phosphorous

This Protocol do not differ in the analytical treatment of the samples from the Protocol for combined manual colorimetric determination of total nitrogen and total phosphorous (4.2) as is based on the identical methodology. The same equipment and chemical reagents must be prepared. The samples prepared and treated in the identical way together with the prepared reagent blanks and standards. At the time when the determination of the nitrate and orthophosphate are necessary the Protocol for automated colorimetric determination of nitrate and orthophosphate must be used for each of the analysed compound. The same problems identified for the automated methods for determination of nitrate and orthophosphate may arise and must be handled as indicated. The calculations are performed as is generally indicated in the Annex I: Automated methods for determination of concentration of key nutrients in seawater – Calculation of the concentration.

Annex I

Automated methods for determination of concentration of key nutrients in seawater – Calculation of the concentration

1. Many automatic nutrient analysis systems are equipped with software that allows, with more or less sophisticated algorithms, to determine the height of the peak and to provide the concentration of the individual samples having previously determined the calibration and the reagent blank value. Although the software may be sophisticated, it is not always able to manage anomalous events, so it is advisable to continuously monitor the operation of the instrument.

3. Considering the current availability of calculation programs such as spreadsheets, the best solution is to obtain from the analyser the values of the three components necessary to calculate the concentrations, i.e. the blank value, that of the baseline near the samples and that of the individual samples. The procedure suggested below is certainly not the only one possible and, once again, it will be up to the operator to decide which paths to follow.

4. Operationally: The instrument is stabilized with the reagents and ultrapure water (DDW) for 15-20 minutes. It is verified that the hydraulics are stable (regular bubbles and stable baseline). The refractive index is then determined by continuously sampling first the ultrapure water (DDW) and then the washing water (OSW), having replaced one of the reagents, usually the one with lower flow rate, with ultrapure water. The difference in reading is recorded which corresponds to the false absorption due to refraction. The replaced reagent is reinserted, and the baseline is re-stabilized with DDW. For the analysis of the samples the DDW is replaced with OSW (the drawing needle is moved from one container to another) and waited for the baseline to re-stabilize. Then the sampler is activated by arranging the samples in groups (usually one or more stations) and taking care to combine the groups with an OSW reading. In this way each group of samples is sandwiched between two OSW readings, which allow a good control of baseline drift. It is also good practice to periodically analyze a series of solutions of known concentration (standards) which must always be prepared daily. Usually, at least one series of standards with increasing concentration is inserted at the beginning of the series of samples and one at the end. If the series of samples is very long, further series of intermediate standards can be inserted. Standards must be in increasing concentrations so that the difference between the lowest and highest includes the range of concentrations expected for the samples to be analysed. This procedure allows both to determine the linearity of response to the Lambert-Beer law (i.e. to determine the slope of the extinction / concentration line of the increasing standards which, in the absence of blank, should pass through the origin of the axes) in the expected concentration range, and to determine any variations in the efficiency of the method (gain) which would be highlighted by significant variations of this slope with the progress of the analysis. In fact, the slope of the initial standardization line, ie its angular coefficient and its reciprocal value F, will almost never coincide with those of the final and / or intermediate standards. The simplest solution to this problem is to take the average between initial, final and / or intermediate F and use this average F_m in the calculation. The most correct, but more complicated, procedure consists in determining the sequential reading "gain" sample by sample, similar to what is done for the calculation of the baseline drift and multiplying the reading value of each sample by its own F so determined. Once the samples have been analysed, it is good practice to re-measure the DDW reading and wash the circuit without the reagents.

5. To calculate the concentrations, the following quantities (the values are in the unit in use, cm if you read on the trace of a recorder or digital counts if you work on the outputs of the A / D converter) must be obtained:

V_{DDW} = value of the DDW reading at the time of blank determination

V_{OSW0} = value of the OSW reading after the blank (DDW)

R = OSW baseline variation in mm by refractive index

V_{OSWi} = value of the OSW reading that precedes the first of the samples of the group

N_{OSWi} = sequential number of the OSW reading that precedes the group of samples

V_{OSWn} = value of the OSW reading that follows the last of the group samples

N_{OSWn} = sequential number of the OSW reading after the last sample of the group

V_s = value of the sample reading

N_s = sequential number of the sample reading

D = drift

F_m = average factor obtained from the standard curves (the reciprocal of the slope or angular coefficient of the straight-line reading-concentration of the calibration samples)

c = concentration of the sample

the concentration of the sample is given by the equation:

$$c(\text{Nut.})/\ \mu\text{mol L}^{-1} = [V_s - D\ (N_s - N_{OSWi}) - V_{OSWi} + (VOSW0 - V_{DDW}) - R]\ F_m$$

where the drift (D) is given by:

$$D = (V_{OSWn} - V_{OSWi}) / (N_{OSWn} - N_{OSWi})$$

6. The refractive index refers to the shift of the baseline in the absence of reactants due to the difference in salinity between deionized distilled water (DDW) and oligotrophic water (OSW).

Monitoring Guidelines/Protocols for Determination of Chlorophyll *a* in Seawater

1. Introduction

1. In the Monitoring Guidelines for Determination of Chlorophyll a in Seawater, the four protocols for determination of the concentration of chlorophyll *a* are elaborated. The concentration of in the sea is an important indicator for the presence of algae and other plant-like organisms that carry out photosynthesis. As such, phytoplankton, which contains the chlorophyll, is an essential element of the food chain in the seas as it provides the food for numerous animals. Variations and changes in the chlorophyll levels are also relevant for the study of the ecology of the sea. At the moment, the water classification scheme on which the assessment of GES regarding Ecological Objective 5 related to eutrophication is based on chlorophyll *a* concentration as presented in the IMAP Guidance Factsheets (UNEP/MAP, 2019) [187].

The IMAP Protocols elaborated within this Monitoring Guidelines for Determination of Chlorophyll *a* in Seawater provide detail guidance on the necessary equipment, chemical reagents, analytical procedures along with appropriate methodologies for measurement of the concentration of chlorophyll *a* in sea water, calculations, data transformation if necessary and identify weak points all endorsed through important notes and possible problems. However, they are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories, which should be tested and accordingly modified, if need be, in order to validate their final results.

This Monitoring Guidelines builds upon the UNEP/MAP Integrated Monitoring and Assessment Programme (IMAP) respectively IMAP Guidance Fact Sheets for IMAP Common Indicators 13 and 14 (UNEP/MAP, 2019); standardized protocols (UNEP/MAP, 2019a)[188] and Data Quality Assurance schemes (UNEP/MAP, 2019b)[189] in order to allow the comparability of the data and build of regional assessment schemes. They also take into account previous Sampling and Analysis Techniques for the Eutrophication Monitoring Strategy of MED POL (UNEP/MAP/MED POL, 2005)[190], however providing detail procedures that are of relevance for IMAP implementation. With the details of the protocols for determination of chlorophyll *a*, the needs of the measurements both in off-shore areas and in narrow coastal areas are addressed.

In the Subchapters “Symbol, units and precision” at the end of each Protocol, for all parameters described in it, the symbol and unit suggested by the International System of Units (SI) are presented. The expected accuracy, precision and where possible the Limit of Detection (LOD) are also presented. A Method identifier is also presented as it is provided in the Library P01 of the British Oceanographic Data Centre (BODC) Parameter Usage Vocabulary respectively included in Data Dictionaries and Data Standards for eutrophication built in IMAP Pilot Info System.

The below flow diagram informs on the category of this Monitoring Guidelines related to determination of chlorophyll *a* in seawater within the structure of all Monitoring guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.

Flow Diagram: Monitoring Guidelines for IMAP Ecological Objectives

2. Technical note for determination of concentration of chlorophyll *a*

In this note the photometric, fluorometric and HPLC methods are presented, that are based on a characteristic common to all autotrophic organisms, i.e., the presence of pigments that allow to capture the light and transfer it to the reaction centres where photosynthesis begins. In the marine environment, except for a small fraction of very ancient bacteria (Kolber et al., 2001)[191], all phototrophic organisms, i.e. those that use light to live, have either chlorophyll *a*, or a very similar pigment, divinyl chlorophyll *a*, while accessory pigments, mostly carotenoids, can change from group to group.

The methods are based on the evidence that the amount of pigments present in a planktonic organism are related with its total biomass. It should also be added that the methods used for the collection of phytoplanktonic biomass (essentially represented by filtration) do not allow to separate the phytoplanktonic carbon from the non-phytoplanktonic carbon (organic debris), simultaneously present in marine water.

In summary, although the carbon measurements are the most correct for an estimate of the phytoplankton biomass, those based on chlorophyll *a* are still the most used, both for historical and practical reasons. In fact, the former, despite the recent technical progress, are more expensive and complicated than those of the pigments proposed here.

These methods, both photometric and fluorometric, are optimal when a limited economic and time commitment is expected, while the recent chromatographic separation techniques of the pigment mixture (essentially by HPLC: Robinson, 1979[192]) are costly and time demanding and not always sustainable for all laboratories.

The wide diffusion of the spectrophotometric method is also motivated by the fact that the instrument used is almost always present in an analytical laboratory, for the many determinations based on the measurement of the absorbance of coloured substances. The contraindication of the

[191] Kolber Z.S., Gerald Plumley F., Lang A.S., Beatty T.J., Blankenship R.E., Vandover C.L., Vetriani C., Koblizek M., Rathgeber C., Falkowski P.G., 2001. Contribution of Aerobic Photoheterotrophic Bacteria to the Carbon Cycle in the Ocean. Science, 292: 2492-2495.
[192] Robinson, A.L., 1979. HPLC: the new king of analytical chemistry. Science, 203: 1329-1332.

spectrophotometric method is its reduced sensitivity, compared to methods based on fluorescence. This entails either the use of cells with a higher optical path (10 cm), which in any case generate the problem of having a larger volume of solvent for extraction and waiting for the reading to stabilize, or for the filtration of large volumes of water. This is not always possible given that in the open sea and in periods other than those of intense blooms, 4-5 L are the minimum quantity necessary to obtain reliable results. Filtering large volumes of water always presents many difficulties, both for sampling, and for increasing the filtration time and for the need to use larger filters and / or ad hoc filtration systems.

On the contrary, the fluorometric method allows to obtain reliable data by filtering smaller quantities of water, using filters of smaller diameter and obtaining lower extract volumes. All these aspects make the measurement of fluorescence in overall more practical and economical, excluding the initial acquisition of a fluorimeter, both with filters and with monochromator, even if recently instruments at affordable costs have been placed on the market. However, it is good to consider that these analytical tools are suitable for fewer applications for environmental analysis. Finally, it should be remembered that all methods of measuring pigment concentrations, including HPLC and fluorometric techniques, are based on calibrations that necessarily use optical density measurements, which makes the use of the spectrophotometer irreplaceable.

The differences between the concentrations obtained by spectrophotometry-UV, fluorimetry, and spectrophotometry is visible; after the chromatography, can be significant if degradation products are present[193]. The simultaneous use of the methods in the same programs is not encouraged.

Under this Technical Note, the Monitoring Guidelines for Determination of Chlorophyll *a* in Seawater elaborates the four following Protocols:

- Protocol for sample pretreatment for determination of concentration of chlorophyll *a;*
- Protocol for spectrophotometric determination of concentration of chlorophyll *a;*
- Protocol for fluorometric determination of concentration of chlorophyll *a;*
- Protocol for HPLC determination of concentration of chlorophyll *a*.

2.1 Protocol for sample pre-treatment for determination of concentration of chlorophyll *a*

After the suspended particulates containing fat-soluble pigments have been concentrated on a glass fibre filter by means of filtration the chlorophyll pigments are extracted from the cells, shredding and by homogenizing the filters, immersed in a mixture of acetone and water.

a. Specific equipment

The equipment for sample pre-treatment includes the following pieces:

i) Centrifuge for 12 mm diameter tubes, capable of reaching 4000 rpm, preferably refrigerated.

ii) Homogenizer (potter) with ground glass or Teflon pestle.

b. Chemical products and reagents

[193] Dos Santos, A.C.A., Calijuri, M.C., Moraes, E.M., Adorno, M.A.T., Falco, P.B.,Carvalho, D.P., Deberdt, G.L.B., Benassi, S.F. 2003. Comparison of three methods for Chlorophyll determination: Spectrophotometry and Fluorimetry in samples containing pigment mixtures and spectrophotometry in samples with separate pigments through High Performance Liquid Chromatography. Acta Limnol .Bras., 15(3):7- 18.

For sample pre-treatment for determination of concentration of chlorophyll *a*, the following products and reagents are needed:

i) Acetone, p.a. [$(CH_3)2CO$]

ii) Sodium carbonate [$NaCO_3$]

iii) Hydrochloric acid [HCl]

iv) 90% v/v neutral acetone: 100 mL of reagent grade water and 900 mL of neutral acetone (see above) separately measured are mixed. The solution is always kept away from light and in the presence of sodium carbonate.

v) Hydrochloric acid 0.66 mol L^{-1}: 55 mL of concentrated hydrochloric acid (HCl 37% v/v) is slowly poured (under stirring) in 950 mL of reagent grade water.

c. Procedure

After filtration, filters are either frozen in liquid nitrogen (after being folded and placed into cryotubes) and transferred at -80°C until analyses or directly placed in the freezer at -80°C. For pigment extraction, frozen filters are directly placed in 90% acetone and triturated and homogenized for a maximum of 2 min by carefully rinsing the pestle of the homogenizer several times.

This operation must be carried out using a volume of acetone equal to that of the pure acetone used to store the filter. Since the final extract must be in 90% acetone and considering that the filter retains water (for a 47 mm GF/F filter about 0.7 mL), generally 5 mL of 90% acetone are added to the 5 ml of pure acetone.

If the sample is analysed immediately after filtration, the shredding and homogenization operations must be carried out directly with 90% acetone. The homogenization of the filter by potter causes a gradual heating of the extraction liquid, with possible partial degradation of the pigments. This inconvenience can be limited by using cold acetone (4 °C) or by placing the test tube in a beaker with ice, in any case containing the operation within a maximum time of 2 minutes.

The sample can also be homogenized by manual shredding with a glass rod, directly inside the test tube used for storage; in this case it is appropriate to estimate quantitatively what the possible decrease in efficiency is, compared to the instrument shredding.

Note, that the use of ultrasound does not seem to give good results (Nusch, 1980)[194] as it produces excessive heating of the extract and is therefore not recommended.

The test tube carefully capped with the obtained suspension (10 mL of 90% acetone) must be kept at 4 °C in the dark for 24 hours to complete the extraction. The closed tubes are centrifugated for 10 minutes at 4000 rpm (or 3500 for 12 minutes, if not refrigerated).

2.2 Protocol for spectrophotometric determination of concentration of chlorophyll *a*

The spectrophotometer to be used should preferably be equipped with an interference grid and a bandwidth of 1-2 nm, with cells of at least 50 mm (preferably 100 mm) with optical path and reduced volume (max 7 mL). It is important that the wavelength is carefully adjusted, frequent checks must be

[194] Nusch, E., 1980. Comparison of different methods for chlorophyll and phaeopigment determination. Arch. Hydrobiol. Beih., 14: 14-35.

carried out following the instructions of the manufacturer of the equipment. For spectrophotometers with a hydrogen or mercury lamp, the respective lines (hydrogen - 656 nm; mercury - 546 nm) must be checked.

With the new generations of diode lattice spectrophotometers these tasks are easier to be performed. They are even connected to a PC that allows data to be stored in digital format and therefore immediately usable for the calculations necessary for estimating concentrations.

a. Reading and calculations

After the final centrifugation of the extract, the supernatant, using a pipette or syringe, is transferred to the cell.

Three different methods for estimating photosynthetic pigments are available:

i) method for estimating chlorophyll *a* with phaeopigments;

ii) method for the separate estimation of chlorophylls *a*, *b* and *c*;

iii)method for the separate estimation of chlorophyll *a* and phaeopigments.

The first method reported involves an error of variable magnitude, due to the presence of both accessory pigments (chlorophylls *b* and *c*) which have an absorption maximum even at 664 nm, both for pheophytins and pheophorbides, the main degradation products of chlorophylls. However, this method is preferable when you want to lower the sensitivity threshold of the estimate (e.g. for concentrations lower than 0.4 µg L^{-1}), as it allows a more "robust" and reliable estimate of the pigment biomass.

The other two methods allow to obtain a more precise estimate of chlorophyll *a* alone in the presence of significant quantities of chlorophyll *b* and *c*, using readings at multiple wavelengths (Jeffrey and Humphrey, 1975[195]; Lorenzen and Jeffrey, 1980[196]) or in the presence of significant quantities of its degradation products, having treated the extract with hydrochloric acid (Lorenzen, 1967)[197].

b. Method 1. Concentration of chlorophyll a

This method is based on the assumption that the maximum absorption peak of chlorophyll *a* is at 664 nm with a specific absorption coefficient of 87.67 cm^{-1} g^{-1} L (Jeffrey and Humphrey, 1975) and the phaeopigments are not present in high quantity.

Absorbance of the sample is read at 664 and 750 nm against a blank of 90%-acetone (not neutralized).

The concentration (*c*) of chlorophyll *a* (Chl *a*) is calculated applying the following formula:

$$c(\text{Chl } a)/\mu g\ L^{-1} = \{[A(s,664)-A(b,664)]-[A(s,750)-A(b,750)]\}\ v\ 10^6/\ (a^*\ op\ V)$$

where:

[195] Jeffrey S.W., Humphrey G.F., 1975. New spectrophotometric equations for determining chlorophylls *a, b, c1* and *c2* in higher plants, algae and natural phytoplankton. Biochem. Physiol. Pfanzen., 167: 191-194.
[196] Lorenzen C.J., Jeffrey S.W., 1980. Determination of chlorophyll in sea water. UNESCO Tech. Pap. Mar. Sci., 35: 1-20.
[197] Lorenzen C.J., 1967. Determination of chlorophyll and phaeopigments spectrophotometric equations. Limnol. Oceanogr., 12: 343-346.

A (s, 664) = Absorbance of the sample at 664 nm;

A (s, 750) = Absorbance of the sample at 750 nm;

A (b, 664) = Absorbance of white at 664 nm;

A (b, 750) = Absorbance of the blank at 750 nm;

a* = specific absorption coefficient of chlorophyll *a* in 90% acetone at 664 nm (87.67 $cm^{-1}g^{-1}$ L)

op = optical path of the cell (cm);

v = volume of the extract (mL); and

V = volume of filtered sample (mL).

c. Method 2. Concentrations of chlorophylls a, b and c

The method should be used to provide accurate estimates of chlorophylls *a*, *b* and $c_1 + c_2$ on phytoplanktonic samples of mixed populations, when no significant quantities of their degradation products are present (Jeffrey and Welschmeyer, 2005[198]; Humphrey and Jeffrey, 2005[199]).

Absorbance at wavelengths of 630, 647, 664 and 750 nm are to be read, to estimate the incidence of the concentration of the chlorophylls *b* and *c* on the concentration of chlorophyll *a* (Lorenzen and Jeffrey, 1980). By applying this method, it is also necessary to read the blanks at respective wavelengths.

Determine the net absorbance of the extract at each wavelength [A (l)] according to the equation:

$$A(l) = [A(s, l)-A(b, l)]-[A(s, 750)-A(b, 750)]$$

where:

A (b, l) = Absorbance of the blank at l nm;

A (s, l) = Absorbance of the sample at l nm;

A (b, 750) and A (s, 750) are defined as above.

Calculate the concentrations of chlorophylls (Chl *a*, *b* and *c*) by applying the following equations:

$$c(\text{Chl } a)/\mu g\ L^{-1} = [11.85\ A(664)-1.54\ A(647)-0.08\ A(630)]\ v\ 10^3/(op\ V)$$

$$c(\text{Chl } b)/\mu g\ L^{-1} = [-5.43\ A(664)+21.03\ A(647)-2.66\ A(630)]\ v\ 10^3/(op\ V)$$

$$c(\text{Chl } c_1+c_2)/\mu g\ L^{-1} = [-1.67\ A(664)-7.60\ A(647)+24.52\ A(630)]\ v\ 10^3/(op\ V)$$

where:

A (l), *op*, *v* and *V* have the meaning already expressed above.

The values of the concentrations of chlorophylls b and c can be negative when these pigments are present in very low concentrations and cannot be determined with this method, or if there are many phaeopigments that disturb the readings.

d. Method 3. Concentrations of chlorophyll a and phaeopigments

The method allows to determine the concentrations of chlorophyll *a* and phaeopigments (pheophytins, pheophorbides, chlorophyllides) assuming that the ratio between their specific absorption coefficients is equal to that between chlorophyll *a* and pheophytin *a* (Lorenzen, 1967).

The analytical procedure involves the addition of 50 µL (one drop) of HCl (0.66 mol L^{-1}) for every 5 mL of extract directly into the spectrophotometer cell immediately after the readings at 665 and 750 nm. The cell must be shaken repeatedly and it is necessary to wait 30 to 60 seconds before repeating the readings at the same wavelengths. In this way, all the chlorophyll *a* present in the extract is converted into pheophytin *a*. It is important to keep in mind that the final acid concentration in the extract must not greatly exceed the value of 3 10^{-3} mol L^{-1} (30 µL of HCl 0.66 mol L^{-1} for each ml of extract), to avoid that the carotenoids present are transformed into a compound that absorbs in the red, thus altering the value of the reading of the phaeopigments (Riemann, 1978)[200].

Determine the net absorbance of the extract before acidification [A (665o)] and after acidification [A (665a)] according to the equation:

$$A(665\alpha) = [A(s, 665\alpha) - A(b, 665\alpha)] - [A(s, 750\alpha) - A(b, 750\alpha)]$$

where:

A(b, 665) = Absorbance of the blank at 665 nm;

A(b, 750) = Absorbance of the blank at 750 nm;

A(s, 665α) = Absorbance of the sample at 665 nm before (α = o) or after acidification (α = a);

A(s, 750 α) = Absorbance of the sample at 750 nm before (α = o) or after acidification (α = a).

The concentrations of chlorophyll *a* (Chl *a*) and phaeopigments are calculated applying the following equations:

$$c(\text{Chl } a)/\mu g\ L^{-1} = 26.73\ [A(665o) - A(665a)]\ v\ 10^3/(op\ V)$$

$$c(\text{Phaeopigments})/\mu g\ L^{-1} = 26.73\ [1.7\ A(665a) - A(665o)]\ v\ 10^3/(op\ V)$$

where:

A(665o) = net optical density of the sample at 665 nm before acidification;

---

A(665a) = net optical density of the sample at 665 nm after acidification;

op, *v* and *V* have the meaning already expressed above.

e. Important notes

Instruments with interferential lattice has an optimal reading range, with respect to the measurement error, between 0.2 and 0.8 absorbance units (Strickland and Parsons, 1968)[201]. The minimum concentration of chlorophyll a at which, using 100 mm cells of optical path, in the extract is 228 µg L^{-1}, which is equivalent to an *in situ* concentration of 0.46 µg L^{-1}, in the case 5 L of sample have been filtered. However, if the optical conditions of the measurement and the accuracy are satisfactory (± 0.002 A), readings are also valid with absorbances, at 664 nm, of 0.050 (Neveux, 1979)[202] corresponding to an *in situ* value of 0.11 µg L^{-1}.

If the absorbance of the blank exceeds 0.008 it is necessary to carefully clean the outside of the cells and if the readings value is still high, it is necessary to immerse the cells in sulphochromic mixture for 10 minutes and then rinse them abundantly with water before to repeat the reading. If the absorbance does not decrease, check that the disturbance is not due to impurities present in the acetone and if necessary, filter it carefully.

The reading at 750 nm gives an estimate of the turbidity of the sample and must not exceed the value of 0.010 of absorbance (i.e. 0.002 for each cm of optical path); otherwise it is necessary to repeat the centrifugation or filter the sample with a syringe equipped with a "Swinnex" support in which a 13 mm diameter Teflon filter with a porosity of 0.2 µm is inserted.

2.3 Protocol for fluorometric determination of concentration of chlorophyll *a*

The estimation of the concentration of chlorophyll *a* and phaeopigments with the fluorometric method is based on the measurement of the fluorescence of the pigments in acetone extract, before and after acidification with hydrochloric acid. The photosynthetically active (chlorophyll *a*) and inactive (phaeopigments) fractions of the chlorophyll pigments present (Yentsch and Menzel, 1963[203]; Holm-Hansen et al., 1965[204]) are measured. Compared to spectrophotometric ones, fluorometric methods are more sensitive, precise and rapid, however the use is recommended only when the concentration of the pigments is low, since, for high values, the relationship between fluorescence and concentration is no longer linear. The upper limit within which the relationship remains such is approx. 750 µg L^{-1} in the acetone extract (Neveux, 1979) and approx. 1.5 µg L^{-1} in sea water (Bianchi, 1986)[205]. In any case, this linearity interval must be verified for each instrument. Furthermore, the validity of these methods is strongly conditioned by the heterogeneity of the pigment mixture, in particular by the concentration of chlorophyll *b* in the acetone extract (Yentsch, 1965[206]; Loftus and Carpenter, 1971[207]; Gibbs, 1979[208]). In fact, the pheophytin *b* produced by the degradation of this pigment shows an emission peak at 651 nm which, inversely to that of pheophytins *a* and *c*, shows a strong increase compared to the corresponding chlorophyll, thus causing, if present, an overestimation of the phage pigments.

[208] Gibbs, C.F., 1979. Chlorophyll b interference in the fluorometric determination of chlorophyll *a* and phaeopigments. Aust. J. Mar. Freshwater Res., 30: 597-606.

Finally, the presence in the samples of other compounds that fluorescence in red should not be underestimated, since they can lead to erroneous estimates of chlorophyll *a* and phaeopigments.

a. Equipment

The equipment for fluorometric determination of concentration of chlorophyll *a* include: i) Spectrophotometer, see considerations in the previous paragraphs; and ii) Filter fluorometer or spectrofluorometer.

If a filter fluorometer is used, it is recommended to use an F474-BL lamp as the light source and a Corning CS.5-60 or Kodak Wratten 47B as excitation filter and a Corning CS.2-64 as emission filter. The instrument must be equipped with a photomultiplier with sensitivity extended to the 800 nm band (e.g. Hamamatsu R446). Even if measurements are taken with a spectrofluorometer, it is necessary to use a photomultiplier with extended sensitivity in the red region. Furthermore, it is necessary to calibrate/check the wavelengths of the monochromators; the simplest calibration consists in the emission scan of a sample of deionized water, placing the excitation monochromator at 350 nm: the maximum peak (called "Raman water peak") must be at 397 ± 2 nm. As a bandwidth, the recommended setting is 4-5 nm in excitation and 10 nm in emission.

b. Procedure

b.1. Fluorometric measurements

After the extract become clear the extracts are transferred to the fluorometric cuvettes.

Fluorometric readings (excitation – exc; emission – ems) are taken at the maximum wavelengths of chlorophyll *a*, (l_{exc} = 430 nm, l_{ems} = 665 nm) if a spectrofluorometer is used;

Two fluorometric readings for each sample are taken: i) F_o: the sample as it is; ii) F_a: the sample after adding 1 drop of a 1N HCl solution (after 1 minute); and the fluorescence range is noted in which all measured samples are included.

b.2. Preparation of the initial standard

A standard solution of pure commercial chlorophyll *a* (stock solution) is prepared by dissolving the standard, supplied in crystalline form, in a 90% (v / v) acetone solution;

The optical density of this solution is read with a spectrophotometer (in general an absorbance at 664 nm equal to about 0.09 units with a 10 mm cell is obtained);

The concentration of the stock solution (in mg L-1) is calculated using the following equation:

$$c(\text{Chl } a)/\mu\text{g L}^{-1} = [A(664) - A(750)].\ (a^* \ op)^{-1}\ 10^6$$

where

A(664) = Absorbance at 664 nm;

A(750) = Absorbance at 750 nm;

a* = specific absorption coefficient of chlorophyll *a* in 90%-acetone at 664 nm (87.67 $cm^{-1}g^{-1}$);

op = optical path of the cuvette, in cm.

The spectra (SPT) are scaned before (SPT_o) and after (SPT_a) acidification of the mother solution with a drop of 1N HCl; saved and the maximum excitation and emission noted.

The spectra have to be compared with those of chlorophyll *a* and pheophytin a reported in the literature, these scans must be repeated frequently to verify the possible existence of degradation processes in progress in the standard solution.

The linearity of the instrumental response must be verified: a series of substandards are prepared for a range of three orders of magnitude, using automatic pipettes or calibrated glassware, with 1:2 dilutions in succession.

Following the same methods of reading the samples (l_{exc} = 430 nm, l_{ems} = 665 nm), each substandard must be read before (F_o) and after (Fa) acidification.

A table containing the dilutions carried out, the concentrations obtained, the fluorescence read before (F_o) and after (F_a) acidification must be prepared.

After bringing the pairs of concentration / fluorescence values on an x-y graph; a linear relationship at low values and a loss of linearity at higher values, caused by self-quenching phenomena present in molecules of fluorescent compounds, such as chlorophylls (Lakowicz, 2006)[209] will be noticed.

It is necessary for each operator to write down the limit beyond which linearity is lost for their instrument.

If the discrete samples show fluorescence values beyond this value, the sample must be diluted to bring it back into the linearity range of the instrumental response

b.3. Routine standardization after fluorometric measurement of samples

After each batch of analysis, starting from the stock solution, a series of 3-5 substandards must be prepared by dilutions, which fall within the fluorescence range obtained from the readings of the samples; and

For each substandard a reading before (F_o) and after (F_a) acidification with HCl must be performed.

c. <u>Calculations of the concentrations of the samples:</u>

The factor C is calculated as the average of the ratios between the 3-5 concentrations of each substandard ($C_{Chl\ a}$) and the relative fluorescence values before acidification (F_o)

The R factor is calculated as the average of the ratios between F_o and F_a for each of the 3-5 measured substandard;

The concentrations of chlorophyll *a* and phaeopigments are calculated from the sample values using the following equations proposed by Holm-Hansen et al. (1965):

$$c(\text{Chl } a)/\mu g\ L^{-1} = R\ (R\text{-}1)^{-1}\ C\ (F_o\text{-}F_a)\ v\ V^{-1}$$

$$c(\text{Phaeopigments})/\mu g\ L^{-1} = R\ (R\text{-}1)^{-1}\ C\ [(R\ F_a)\text{-}F_o)]\ v\ V^{-1}$$

[209] Lakowicz J. R., 2006. Principles of Fluorescence Spectroscopy. 3rd ed. Springer, Berlin: 954 pp.

where:

R = F_o / F_a average;

C = C (Chl a) / average *Fo*;

F_o = fluorescence of the sample before acidification;

F_a = fluorescence of the sample after acidification;

v = volume of the extract (mL);

V = volume of filtered sample (mL).

2.4 Protocol for High-Pressure Liquid Chromatography (HPLC) determination of concentration of chlorophyll *a*

The separation of pigments is possible thanks to their difference in polarity which determines the affinity between a mobile phase (elution solvents) and a stationary (column). In practice, it is determined by their different speed of crossing the column (composed of a support consisting of silicon and molecules of C18 or C8) which represents the stationary phase, while the mixture of solvents and pigments, which runs through the column, forms the mobile phase. The stationary phase is less polar than the mobile phase and, therefore, a reverse phase HPLC is implied. The polarity of the mobile phase varies over time, thus the pigments adsorbed on the stationary phase are eluted and therefore sequentially separated from the phase mobile according to their polarity gradient. Typically, an elution gradient is used that allows to decrease the retention time of the less polar compounds and, consequently, to increase the sensitivity of the method.

Once separated, the pigments are detected and quantified according to spectrophotometric methodologies and / or fluorometric. The result of the analysis is a chromatogram (spectrophotometric and/or fluorometric), in which the position of the peaks on the time axis allows to identify the different pigments present in the sample, while from the peak areas it is possible to quantify them. With the chromatogram obtained with a spectrophotometric detector the identification and quantification of both chlorophylls and carotenoids is allowed, while from the fluorescence chromatogram the identification of only the chlorophylls and their degradation products are possible.

Currently, the most accurate spectrophotometric detectors are diode ones (Diode Array Detector: DAD) which allow the determination of the absorption spectrum of each pigment; this allows, not only to quantitatively determine the chlorophylls and carotenoids, but also to evaluate their purity. In the absence of a DAD spectrophotometric detector it is advisable to use methods with analysis times longer that limit the overlap of the peaks. The solvent gradient, flow and run time (20-40 min) are characteristic of the selected method. However, it is advisable to seek optimization of the method to minimize time and amount of solvents and maximize the resolution of the pigments.

While these chromatographic separation techniques of the pigment mixture are costly and time demanding and not always sustainable for all laboratories routine work. If the choice of implementing this method for chlorophyll *a* analysis is selected, due to the complexity in choosing the various components in order to optimize the cost /effectiveness of the apparatus that build the method it is advisable to start with consulting chapters 9 and 11 of the “Monograph on Oceanographic methodology (UNESCO Publishing, Publishers: Jeffrey SW, Mantoura RFC and Wright SW, 1997[210])

[210] Jeffrey, S. W.; Mantoura, R. F. C.; Wright, S. W., 1997. Phytoplankton Pigments in Oceanography: Guidelines to Modern Methods. UNESCO Publishing: Paris, 691 pp.

(Wright et al., 1997[211] and Mantoura et al., 1997[212], respectively). The most complete, up-to-date information about the analysis of pigments, particularly for the use of aquatic scientists, can be found in a recent book edited by Roy, Llewellyn, Egeland and Johnsen (2011)[213].This book follows the 1997 monograph edited by Jeffrey, Mantoura and Wright and together, these two books cover sample collection, methods for pigment extraction and analysis, with emphasis on HPLC methods, comparisons with non-chromatographic methods, preparation of pigment standards and a key for identification of the various algal pigments.

a. Symbol, units and precision

For the parameter described in this protocol, the symbol and unit suggested by the International System of Units (SI), as well as the expected accuracy, along with a Method identifier as provided in the Library P01 of BODC Parameter Usage Vocabulary are provided as follows:

Symbol: *c*(Chl a) **Unit:** µg L^{-1}

Precision: 0.01 **Accuracy:** ± 0.05

Method identifier:	SDN:P01::**CPHLSXP1**	Concentration of chlorophyll-a {chl-a CAS 479-61-8} per unit volume of the water body [particulate >GF/F phase] by filtration, acetone extraction and spectrophotometry
	SDN:P01::**CPHLFLP1**	Concentration of chlorophyll-a {chl-a CAS 479-61-8} per unit volume of the water body [particulate >GF/F phase] by filtration, acetone extraction and fluorometry
	SDN:P01::**CPHLHPP5**	Concentration of chlorophyll-a {chl-a CAS 479-61-8} per unit volume of the water body [particulate >0.2um phase] by filtration, acetone extraction and high performance liquid chromatography (HPLC)

Appendix 16

Monitoring Guidelines/Protocols for Sampling and Sample Preservation of Sediment for IMAP Common Indicator 17: Heavy and Trace Elements and Organic Contaminant

1. Introduction

1. Determination of the concentrations of targeted heavy metals and organic contaminants in different marine matrices is a key component of the IMAP, since the analytical results will contribute to the assessment of the environmental status of the water body under consideration. Sediment is one of the proposed matrices for the analysis of heavy metals since the establishment of the UNEP/MAP – MED POL Monitoring programme in 1981 (MED POL Phase II), because heavy metals and persistent organic contaminants in seawater tend to become insoluble and precipitate with the particulate fraction on the seafloor. Therefore, since sediment is the ultimate sink of most heavy metals and persistent organic contaminants, which are introduced into the marine environment, their analysis will provide a clear view of the pollution state of the specific water body. Furthermore, in areas with undisturbed sediments, the yearly deposited sedimentary material integrates the pollution load during this specific time period, and the analysis of different sedimentary layers is providing a historical trend of pollution processes in the region.

2. The UNEP/MAP Integrated Monitoring and Assessment Programme (IMAP) (UNEP/MAP, 2019[214]; UNEP (2019a[215]), requires sediment sampling from the top layer of the seafloor, because this layer reflects the recently deposited material, therefore the actual status of pollution at the specific location. The depth of the "recently" deposited sediment varies from one location to another, influenced by the sedimentation rate but also by bioturbation, but in the coastal zone it is usually the top 1 to 5 cm from the seafloor surface. In open sea, the sedimentation rate is lower than in the coastal zone, therefore often the 1st cm of the sediment may be representing several deposition years. It is of paramount importance to collect the undisturbed top layer of the sediment for analysis. Therefore, the use of appropriate sampling equipment is very important, as well as the proper handling during sampling to collect a representative sediment sample.

3. Until now, UNEP/MAP – MED POL pollution monitoring programme was focussing on the marine coastal zone, which was affected by land-based pollution sources. Therefore, sediment sampling was mainly done in relatively shallow waters, although some Contracting Parties were also collecting sediment samples from deeper waters. In a view of extending monitoring to much deeper offshore areas in the framework of the IMAP, sediment collection protocols are also addressing sediment sampling procedures from such offshore environments. Box corers and multiple corers are mostly suitable for such offshore sediment sampling, while gravity corers can be mainly used for tracking historical pollution trends. It has to be underlined that sedimentation rates at offshore sediments are much lower than in the coastal zone, leading to a much lower yearly deposition of sediment material on the seafloor. Therefore, in order to decide on the appropriate sediment depth to be collected for recording recent contaminants' concentrations, as well as on the required sampling frequency in offshore sediments in view of detecting possible changes in contaminants accumulation, the determination of the sedimentation rate at the sampling stations is highly needed.

4. Once a representative sediment sample has been collected, it has to be transported to the laboratory for analysis. However, transportation has to be done in such a way as to avoid any alteration of the physical and chemical characteristics of the sample. Sediment characteristics and contaminants distribution in the sample may be altered if the sediment storage and transportation is not done under specific procedures, in order to avoid sample alteration and cross contamination from the material of the containers and the sampling and transportation environment.

[214] UNEP/MAP (2019). UNEP/MED WG.467/5. IMAP Guidance Factsheets: Update for Common Indicators 13, 14, 17, 18, 20 and 21: New proposal for candidate indicators 26 and 27; UNEP (2019).
[215] UNEP/MAP (2019a). UNEP/MED WG.463/6. Monitoring Protocols for IMAP Common Indicators related to pollution;

5. The Protocols prepared in the framework of this Monitoring Guidelines for Sampling and Sample Preservation of Sediment for IMAP Common Indicator 17, as provided here-below, describe appropriate methodologies for sampling, processing and storage of marine sediment under controlled conditions to ensure the representativeness and the integrity of the samples. They are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories, which should be tested and modified in order to validate their final results.

6. These Protocols aim at streamlining sediment sampling and sample preservation in order to assure comparable quality assurance of the data, as well as comparability between sampling areas and different national monitoring programmes. They provide a step-by-step guidance on the methods to be applied in the Mediterranean area for sampling and sample preservation of sediments in a view of their subsequent analysis for heavy metals and organic contaminants.

7. In order to avoid unnecessary repetitions, reference is also made to the protocols already published and publicly accessible, which can also be used by the Contracting Parties' competent laboratories participating in IMAP implementation. They build upon the UNEP/MAP (2011[216]) Manual on sediment sampling and analysis (Annex I), as well as similar Guidelines/Protocols for marine sediment sampling which were developed by other Regional Seas Organisations, such as ICES/OSPAR (2018[217]) CEMP Guidelines for Monitoring Contaminants in Sediments and HELCOM (2012[218]) Manual for marine monitoring in the COMBINE programme, as well as EC (2010[219]) Guidance on chemical monitoring of sediment and biota under the Water Framework Directive, given their suitability for application in the context of IMAP. Given the suitability of any of these Guidelines in the context of IMAP, they could be further used by interested IMAP competent Mediterranean laboratories for developing their laboratory specific sampling and sample processing methodologies.

8. The below flow diagram informs on the category of this Monitoring Guideline related to sampling and sample preservation of sediment for IMAP Common Indicator 17 within the structure of all Monitoring Guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.

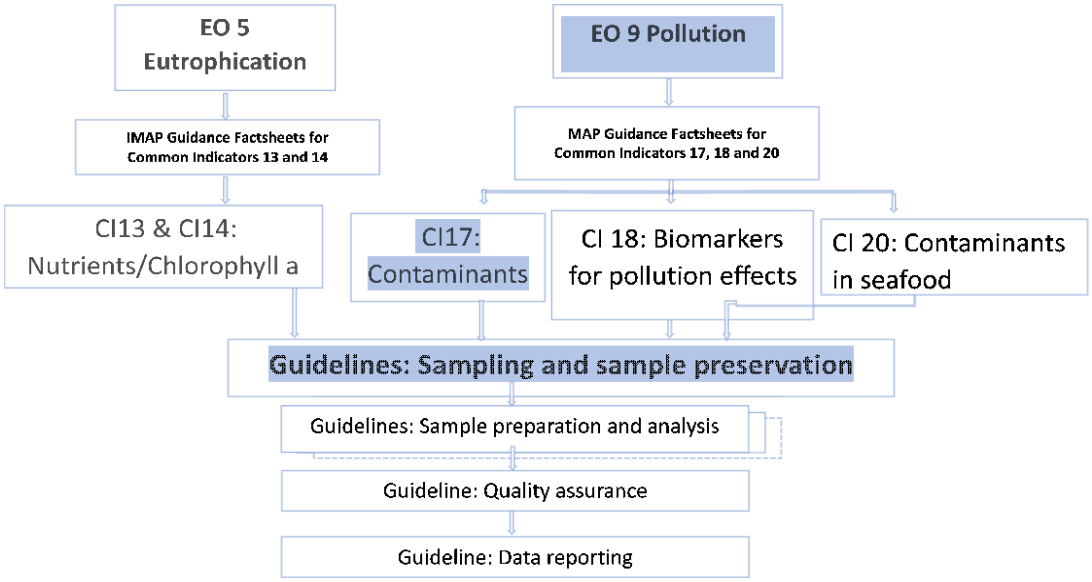
[219] EC (2010). Guidance Document No: 25 Guidance on chemical monitoring of sediment and biota under the Water Framework Directive



Flow Diagram: Monitoring Guidelines for IMAP Ecological Objectives 5 and 9

2. Technical note for the sampling of sediment for the analysis of heavy metals and organic contaminants

9. Sediment sampling for pollution monitoring aims at the collection of a representative sediment sample from the top layer of the seafloor, because this layer reflects the recently deposited material, therefore the actual status of pollution at the specific location. The depth of the "recently" deposited sediment varies from one location to another, influenced by the sedimentation rate but also by bioturbation. Usually it is recommended (EC, 2010) to sample the top layer of the sediment, from 1 to 5 cm depth, depending on the deposition rate. In open sea, the sedimentation rate is lower than in the coastal zone, while at coastal areas at the vicinity of large rivers the sediment sampling depth for recently deposited sediments could be more than 5 cm. During the initial phase of the IMAP (identification of key sampling sites/stations) sediment sampling should be done every two years, while during the advanced phase (when it is a fully completed MED POL Phase IV implementation with the ongoing reporting of IMAP data sets) sampling should be done every 3 to 6 years, depending on the characteristics of sedimentation areas and the chemical concerned known through previous MED POL assessments (UNEP, 2019).

10. To avoid erroneous sampling, it is of paramount importance to sample the undisturbed top layer (1-5 cm) of the sediment using the appropriate sampling equipment. Box corers are the most appropriate equipment to sample undisturbed top layers sediments in the coastal zone and the open sea, but they are relatively heavy and require adequate shipping facilities. In relatively shallow coastal areas, a grab sampler is a good solution, because it is portable and can be used from a coastal vessel, without special equipment for lowering and lifting the sampler from the seafloor. In very shallow sampling sites with a water depth less than 30 cm, surface sediment samples (5 cm) can be collected with a shovel, spatula or scoop, if no other sampling equipment is available.

11. Sediment monitoring generally addresses the top layer of the sediment because this layer indicates the actual deposited material and the actual status of pollution. Furthermore, the top layers of the sediment form the habitat of benthic organisms and therefore may affect their contaminants'

uptake (EC, 2010, UNEP/MAP, 1999[220], UNEP/MAP, 2011). Surface sediments can be collected with grabs and box corers, while gravity corers can be used to collect cores to study historical pollution trends at a specific site. Also, corers could be used in order to collect deeper sediment layers in view of establishing the background concentration of contaminants at a specific area.

12. Under this technical Note, the Guideline for Sampling and Sample Preservation of Sediment for IMAP Common Indicator 17 provides the following IMAP Protocols:

- Protocol for the use of a grab for collecting sediments;
- Protocol for the for the use of a box corer for collecting sediments;
- Protocol for the use of a multi-corer for collecting sediments;
- Protocol for the use of a gravity corer for collecting sediments;
- Protocol for the hand collection of sediment with a shovel/scoop and a hand-held corer.

13. These Protocols are based on methods for sediment sampling and processing developed by UNEP/MAP (Annex I: UNEP/MAP (2011), UNEP(DEPI)MED WG.365/Inf.9. Manual on sediment sampling and analysis), EC (2010) Guidance Document No 25, HELCOM (2012) Technical note on the determination of heavy metals and persistent organic compounds in marine sediment, and ICES/OSPAR (2018) CEMP Guidelines for Monitoring Contaminants in Sediments. In each protocol the operation and the proper deployment and recovery of the sampling equipment is presented, and guidelines are provided for the appropriate taking of the sediment sample in order to preserve its integrity and to avoid contamination.

2.1 Protocol for the use of a grab for collecting sediments

a. Grab operation

14. A tightly closing grab, which is handled with care, can collect relatively undisturbed surface sediment samples. Grabs are not the preferable sampling equipment for collecting undisturbed sediment samples because their penetration in the sediment may disturb the recently deposited sediment layers. However, grabs may provide a workable sampling solution in relatively shoal waters, which are out of the reach of an oceanographic vessel, or when an oceanographic vessel equipped with a box corer is not available. A light-weight hand-held grab is suitable for collecting approximately 250 ml of sediment, which is an appropriate volume for sediment analysis (Figure 1).

Figure 1. Van Veen Grab

[220] UNEP/MAP (1999). MED POL Phase III. Programme for the assessment and control of pollution in the Mediterranean Region.

15. To improve the sampling procedures the sampling vessel should be equipped with some sampling facilities, such as a winch, davit or other such lifting equipment. However, in very shallow coastal waters (for example less than 20 m depth) a small hand-held grab can be used with success from a small boat.

16. The grab is lowered locked-open and upon hitting the sediment's surface the lock is released and the grab's jaws are closing penetrating thus into the sediment to a depth depending on the size and the weight of the grab, as well as the hardness of the sediment.

17. Grabs can be used efficiently in sand or consolidated sediments collecting a good volume of undisturbed sample. On the other hand, in hard clays the grab may not be able to penetrate the hardened sediment, while in un-consolidated soft sediments the grab will sink through the top layer disturbing sediment stratigraphy.

b. Taking the sample

18. The water depth at the sampling station should be recorded before the deployment of the grab in order to ensure that appropriate wire/rope length is available.

19. During the descent of the grab through the water column it is important to control the speed of deployment, to allow the grab arriving at the sediment floor jaws-first. If the grab falls aside on the sediment, sampling will be unsuccessful and the grab has to be lifted, locked-open again and lowered once more. Controlling the speed of the grab's deployment will keep the wire stretched and the grab in a vertical position, as needed.

20. Another factor affecting the successful deployment of the grab is the existence of near-bottom currents that may deflect the grab from the vertical line, resulting in unsuccessful sampling. Additional weight on the grab sampler, as well as longer wire than the actual depth at the station, may be needed.

21. Once the grab is closed at the sediment floor it has to be lifted to the surface. At this stage it is important to avoid any leakage of fine-grained sediment from the grab. If the grab is well designed, no loss of collected sediment should occur. However, leakage can occur if the grab is not tightly closed because of ill-design or because of partial closure of the jaws, caused by obstruction from coarse material (for example coarse sand or shell).

22. When the grab is lifted on-board it has to be positioned on a clean surface and handled with care to ensure that no alteration of the sediment characteristics will occur because of contamination.

i) Pose the grab on a clean surface (plastic).

ii) Visually inspect the collected sample from the small trap doors on top of the grab to make sure that the sediment collected is undisturbed. If water is trapped on the top of the sediment remove it using a glass tube or allow to be slowly drained in order to avoid washing off the top fine-grained layers that may be present.

iii) Record the visual characteristics of the sediment, such as grain size (fine or coarse grained), colour, smell and the presence of organisms. Taking a photo of the collected sediment is also recommended, in order to keep a visual record of the collected sample. If required, you can measure additional parameters, such Eh and pH.

c. Avoiding contamination

23. Grabs are made of metal therefore the best solution for trace metal determinations is to use a stainless-steel grab and, as an additional precaution, use plastic tools to collect subsamples from the

central part of the sample, avoiding the sediment which is in contact with the grab's walls. If possible, use grabs with Teflon coatings on all surfaces that come into contact with the sediment. The use of lowering cables coated with plastic (polyethylene) or of synthetic ropes will further minimize possible contamination.

24. After the water is drained, open the grab carefully on a clean and metal-free area (for example a plastic sheet) to collect the samples for heavy metal analysis. For the analysis of organic contaminants, the grab should be open in a dust-free area avoiding contact with possible sources of contamination from organic pollutants (such as exhaust gases).

25. Remove with a plastic or stainless-steel spoon the top layer, which is representing recent sedimentation. The depth of this layer may vary from 1 to 5 cm depending on the sedimentation rate in the sampling site and has to be decided by the institution that is responsible for the sampling.

26. It is important to ensure that enough sediment material is collected to allow for analysis of heavy metals, organic contaminants, as well as additional sediment analyses (such as grain size). The EC Guidance on sediment sampling (EC, 2010) suggests to collect 50 ml of wet sediment for heavy metal analysis. Taking into consideration that a small hand-held grab can collect approximately 250 ml of sediment, it is a suitable equipment to collect sediment samples for contaminants' analysis at shallow waters. When a larger grab is used, the collected sediment provides enough material for further analysis.

27. Surface sediment samples are transferred into wide-mouth, pre-cleaned containers:

i) Zip-lock bags, plastic (polyethylene, polypropylene), or glass are suitable container's materials for sediments to be analysed for heavy metals;

ii) Glass or aluminium are suitable container's materials for sediments to be analysed for organic contaminants.

28. Containers and zip-lock should be filled to the top to reduce the likelihood of oxidation during transport.

29. Sediment samples have to be stored at 4°C in a cooler box and transported to the laboratory for further processing and analysis.

Protocol for the use of a box corer for collecting sediments

a. <u>Box corer operation</u>

30. A box corer is a sediment sampling equipment, which collects large diameter undisturbed cores, from which replicate sub-samples may be collected by a hand-operated corer (Figure 2). Box corers are relatively heavy and are operated from a ship with appropriate equipment (heavy winch) in water depths more than 3 m (EC, 2010). Usual models collect sediment samples with a penetration of 0.75 m with a surface of 0.25 m^2, although there are smaller box corers available on the market. The big advantage of box corers is that they collect a virtually intact sediment core. If properly handled box corers operate efficiently in all kinds of bottoms, hard, soft or unconsolidated, retrieving undisturbed sediment cores. Therefore, if available, they are the preferable equipment for sediment sampling.

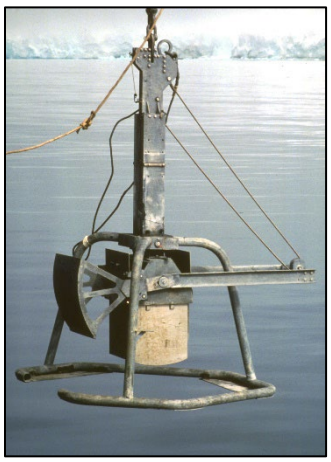


Figure 2. Box corer

b. Taking the sample

31. The water depth at the sampling station should be recorded before the deployment of the box corer in order to ensure that appropriate wire length is available.

32. The box corer is armed (locked-open) and is lowered from the ship with a controlled speed to allow the corer arriving upright at the sediment floor. Controlling the speed of the box corer's deployment will keep the wire stretched and the equipment in a vertical position, as needed. Another factor affecting the successful deployment of the box corer is the existence of near-bottom currents that may deflect it from the vertical line, resulting in unsuccessful sampling. Additional weight on the box corer, as well as longer wire than the actual depth at the station, may be needed.

33. Upon arriving at the sediment's surface, the box corer is penetrating the sediment depending on the hardness of the bottom.

34. Once the core box is filled with sediment, the winch operator slowly recovers the lifting wire and box corer ensuring the lowering of the cutting edge of the spade into the sediment to close the bottom of the box.

35. Once the box corer is lifted on board it has to be positioned on a clean area and secured.

i) Visually inspect the collected sample from the inspection door on top of the box corer to make sure that the spades have are closed tightly and the sediment collected is undisturbed.

ii) Siphon the supernatant water off the sample with a plastic or glass tube and stored it in pre-cleaned bottles, if additional seawater analysis is planned.

iii) Record the visual characteristics of the sediment, such as grain size (fine or coarse grained), colour, smell and the presence of organisms. If required, you can measure additional parameters, such Eh and pH.

36. Record the depth of the core penetration in order to decide if the sampling can be considered successful (appropriate sediment penetration).

c. Avoiding contamination

37. Box corers are made of metal (usually stainless steel) therefore they have to be handled with care, to avoid contamination in the determination of heavy metals. Once the box corer is open on a clean area on the deck of the ship, subsamples can be taken by hand-held plastic coring tubes for metal analysis, and by metallic tubes for organic contaminants analysis. The diameter of these coring tubes depends on the surface of the sediment retrieved with the box corer, as well as the number of subsamples required. The depth of the sediment retrieved for analysis may vary from 1 to 5 cm depending on the sedimentation rate in the sampling site and has to be decided by the institution that is responsible for the sampling. In all cases it is important to ensure that enough sediment material is collected to allow for analysis of heavy metals, as well as additional sediment analyses (such as grain size). The EC Guidance on sediment sampling (EC, 2010) suggests to collect 50 ml of wet sediment for heavy metal analysis and 250 ml for the analysis of organic contaminants. All tools for handling sediment for metal analysis should be made by plastic tools, while metallic tools have to be used for handling sediment for organic contaminants' analysis.

38. Sediment sub-samples are transferred into wide-mouth, pre-cleaned containers:

i. Plastic (polyethylene, polypropylene) or glass are suitable container's materials for sediments to be analysed for heavy metals;
ii. Glass or aluminium are suitable container's materials for sediments to be analysed for organic contaminants.

39. Containers and zip-lock bags should be filled to the top to reduce the likelihood of oxidation during transport.

40. If the contaminants profile will be studied, the cores collected from the box-corer have to be sliced on board to preserve their integrity. If un-sliced cores are transported in horizontal position, the profile characteristics may be lost because of mixing of layers. On the other hand, if cores are transported in vertical position, they may be compacted because of vibration altering the thickness of core's depositional layers. The core sub-samples are transferred to pre-cleaned containers: plastic (polyethylene, polypropylene) or glass are suitable container's materials for sediments to be analysed for heavy metals, while glass or aluminium are suitable container's materials for sediments to be analysed for organic contaminants.

41. Samples have to be stored at 4°C in a cooler box and transported to the laboratory for further processing and analysis.

2.2 Protocol for the use of a multi-corer for collecting sediments

a. Multi-corer operation

42. A multi-corer is a sediment sampling equipment, with several corers joined together (usually 4 to 12 corers) (Figure 3). The multi-corer is lowered from a ship and when it touches the seafloor, its weight pushes the assembled cores into the sediment. When the multi-core is lifted, individual corers' tops and bottoms are closed in order to bring an undisturbed sediment on board. Multi-corers are relatively heavy and can be operated from a ship with appropriate equipment (heavy winch) in water depths more than 3 m, as well as in offshore waters (EC, 2010). Usual models collect sediment cores of 0.7 m length and a coring tube diameter 0.1 m, although there are smaller multi-corers available in the market. The big advantage of multi-corers is that they collect several virtually intact sediment cores, which can be used for the analysis of different parameters (heavy metals, organic contaminants, grain sizes, etc.). Multi-corers can also be used for dating sediment layers. If properly handled multi-corers operate efficiently in all kind of bottoms, hard, soft or unconsolidated, retrieving undisturbed sediment cores.

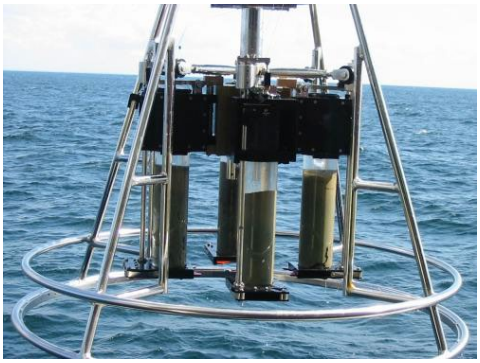

Figure 3. Multiple corer

b. Taking the sample

43. The water depth at the sampling station should be recorded before the deployment of the multi-corer in order to ensure that appropriate wire length is available.

44. The multi-corer is armed (locked-open) and is lowered from the ship with a controlled speed, in order to arrive at the bottom in an upright position.

45. During the descent of the multi-corer through the water column it is important to control the speed of deployment, to allow the corer arriving upright at the sediment floor. A speed of descent of 1 m/s is considered appropriate for the deployment of the device. Controlling the speed of the multi-corer's deployment will keep the wire stretched and the equipment in a vertical position, as needed.

46. Upon arriving at the sediment's surface, the individual corers are penetrating the sediment driven by the weights. Penetration depth depends on the hardness of the bottom.

47. Once the cores have penetrated the sediment, the winch operator slowly recovers the lifting wire and multi-corer, and upon detaching from the sediment, the core tubes are sealed, being capped both top and bottom, preserving the integrity of the samples, and the multi-corer is recovered to the surfaces.

48. Once the multi-corer is lifted on board it has to be positioned on a clean area and secured.

i) Visually inspect the collected cores to make sure that both ends of the coring tubes are properly closed and the sediment collected is undisturbed;
ii) Siphon the supernatant water off the samples with a plastic or glass tube and stored it in pre-cleaned bottles, if additional seawater analysis is planned;
iii) Record the visual characteristics of the sediment, such as grain size (fine or coarse grained), colour, smell and the presence of organisms. If required, you can measure additional parameters, such Eh and pH;
iv) Record the depth of the core penetration in order to decide if the sampling can be considered successful (appropriate sediment penetration).

c. Avoiding contamination

49. Multi-corers have coring tubs made of plastic (acrylic or polycarbonate) for heavy metal analysis or stainless steel for organic contaminants or granulometric analysis. Therefore, appropriate coring tubes should be used for specific measurements. The sizes of the individual coring tubes vary, however usual models collect sediment cores of 60-70 cm length with a coring tube diameter of 10 cm. The depth of the sediment which represents the surface, recently deposited material may vary from 1 to 5 cm depending on the sedimentation rate in the sampling site and has to be decided by the

institution that is responsible for the sampling. However, in all cases it is important to ensure that enough sediment material is collected to allow for analysis of heavy metals, as well as additional sediment analyses (such as grain size). The EC Guidance on sediment sampling (EC, 2010) suggests to collect 50 ml of wet sediment for heavy metal analysis and 250 ml for the analysis of organic contaminants. As an example, if the top 5 cm are retrieved from a coring tube with an internal diameter of 10 cm, the sediment volume collected is 390 cm^3.

50. Multi-corers can also be used to collect deeper sediment layers cores for dating historic pollution trends. The length of the core is restricted to 70-100 cm, which may be enough for recent pollution studies. All sediment handling tools for metal analysis, including core slicer to retrieve specific sediment layers, should be made by plastic, while metallic tools have to be used for handling sediment samples for organic contaminants' analysis. Samples are transferred into pre-cleaned containers: plastic bags or containers for heavy metal analysis and glass or aluminium for organic analysis.

51. In order to preserve the integrity of cores, it is preferable to slice them on board and to store the samples of the different sediment layers. If un-sliced cores are transported in horizontal position, the profile characteristics may be lost because of mixing of layers. On the other hand, if cores are transported in vertical position, they may be compacted because of vibration altering the thickness of core's depositional layers

52. Sediment samples are stored at 4 ^oC on board in a cooler box and are transported to the laboratory for further processing and analysis.

2.3 Protocol for the use of a gravity corer

a. Gravity corer operation

53. A gravity corer consists of a metallic corer tube with a plastic internal liner and attached weights that enables penetration into the sediment (Figure 4). The gravity corer is used for taking relatively long cores to study sediment layers. It is a heavy equipment (could be hundreds of kilograms), which is usually operated from a ship equipped with a heavy winch for relatively deep waters. Smaller gravity corers may be available but, they also need a boat and a winch to be handled. Gravity corers are mostly used to study contaminants' variation between sediment layers, or to record pre-industrial background concentrations of contaminants, rather than studying recent pollution changes. They can be used in both coastal and offshore sediments, taking into consideration the respective sedimentation rates, in order to evaluate the analytical results.

Figure 4. Gravity corer

54. The gravity corer is lowered from a ship and when it touches the seafloor, its weight pushes the corer tube into the sediment. Penetration depth depends on the hardness of the bottom and the weight added on top of the corer's tube. It has to be noted that because of the gravity-driven penetration of the corer into the sediment and the relatively small diameter of the coring tube, the retrieved sediment layers may be compressed and/or stretched, which may result in misleading geochronology results.

b. Taking the sample

55. The water depth at the sampling station should be recorded before the deployment of the gravity corer in order to ensure that appropriate wire length is available.

56. During the descent of the corer through the water column it is important to control the speed of deployment, to allow the corer arriving upright at the sediment floor. Controlling the speed of the gravity corer's deployment will keep the wire stretched and the equipment in a vertical position, as needed.

57. Once the corer has penetrated the sediment, the winch operator slowly recovers the lifting wire and when the corer is lifted from the seafloor the "orange peel" closing system prevents the loss of the collected sediment, preserving the integrity of the sediment layers.

58. Once the gravity corer is lifted on board it has to be positioned on a clean area and secured.

i) Remove the inner liner of the corer and record the visual characteristics of the sediment, such as grain size (fine or coarse grained), colour, smell and the presence of organisms. If required, you can measure additional parameters, such Eh and pH.

ii) Record the depth of the core penetration in order to decide if the sampling can be considered successful (appropriate sediment penetration).

iii) Slice the core using a core slicer, according to predefined sections. Surface sediment, which represents recent deposition, may correspond to the upper 1 - 5 cm, according to the sedimentation rate in the area, while the core intervals, which correspond to past deposition times will be defined by the leading scientist.

c. Avoiding contamination

59. Gravity corers collect only one core at a time, therefore if a plastic liner is used the collected sediment can be used for heavy metal analysis only. Stainless steel or Teflon liners can be used for collecting sediments for organic contaminants analysis. The depth of the sediment which represents the surface, recently deposited material may vary from 1 to 5 cm depending on the sedimentation rate in the sampling site and has to be decided by the institution that is responsible for the sampling. It is important to ensure that enough sediment material is collected to allow for analysis of heavy metals, as well as additional sediment analyses (such as grain size). The EC Guidance on sediment sampling (EC, 2010) suggests to collect 50 ml of wet sediment for heavy metal analysis and 250 ml for the analysis of organic contaminants.

60. Gravity corers are mainly used to collect deeper sediment layers for dating historic pollution trends. All sediment handling tools for metal analysis, including core slicer to retrieve specific sediment layers, should be made by plastic, while metallic tools have to be used for handling sediment samples for organic contaminants' analysis. Samples are transferred into pre-cleaned containers: plastic bags or containers for heavy metal analysis and glass or aluminium or other non-contaminating material for organic analysis.

61. In order to preserve the integrity of cores, it is preferable to slice them on board and to store the samples of the different sediment layers. If un-sliced cores are transported in horizontal position, the profile characteristics may be lost because of mixing of layers. On the other hand, if cores are transported in vertical position, they may be compacted because of vibration altering the thickness of core's depositional layers

62. Sediment samples are stored at 4 ºC on board in a cooler box and are transported to the laboratory for further processing and analysis.

2.4 Protocol for hand collection of sediment with a shovel/scoop and a hand-held corer

a. Hand shovel/spatula operation

63. In mud flats or in very shallow water zones with a water depth less than 30 cm, surface sediment samples (5 cm) can be collected with a shovel, spatula or scoop, if no other sampling equipment is available (Figure 5). This method can be used to collect both unconsolidated and consolidated sediment; however, it is more accurate when used in relatively calm waters. The person who will take the sample has to walk with care into the water, avoiding disturbing the site to be sampled and using a shovel/spatula/scoop he/she collects the desired thickness of the sediment. The depth of the sediment which represents the surface, recently deposited material may vary from 1 to 5 cm depending on the sedimentation rate in the sampling site, and it has to be decided by the institution that is responsible for the sampling. It is important to ensure that enough sediment material is collected to allow for analysis of heavy metals, as well as additional sediment analyses (such as grain size). The EC Guidance on sediment sampling (EC, 2010) suggests collecting 50 ml of wet sediment for heavy metal analysis and 250 ml for the analysis of organic contaminants.

64. The sample collected is transferred to a pre-cleaned container. The excess water should be removed before closing the container with the sediment sample.

Figure 5. Hand-held scoop sediment sampler

b. Avoiding contamination

65. To avoid contamination during sampling the sampling utensil (shovel/spatula/scoop) has to be made of plastic for heavy metal analysis and of stainless steel for organic contaminants analysis. The containers used to store the sediment samples should be pre-cleaned and made of plastic for heavy metal analysis or of metal/glass for organic contaminants analysis.

66. Sediment samples are stored at 4 ºC on board in a cooler box and are transported to the laboratory for further processing and analysis.

3. Technical note for the preservation of sediment sample to be analysed for heavy metals and organic contaminants

67. After collection wet sediment samples have to be treated in order to be preserved unaltered until transfer to the analytical laboratory for heavy metals analysis. Sediment sample preservation include: i) Storage of wet samples on board; ii) Wet sieving to collect the grain size fraction < 2 mm, which will be further analysed for organic contaminants; iii) Freeze drying to prepare the sample for

the analysis and iv) Homogenization and storage of dried sediments. Wet sieving may also include an additional step to define the percentage (weight) of the silt and clay fraction of the sediment (< 63 μm), which is a useful parameter in assessing pollution in sediments. For the processes, the Protocol includes all necessary precautions to avoid cross-contamination of the sediment samples from tools, equipment and the laboratory environment.

68. The IMAP Protocol 3.1. addresses the treatment of sediment samples prior to analysis for heavy metals and organic contaminants.

3.1 Protocol for the treatment of sediment sample prior to analysis

a. Storage of wet samples on board

69. Upon collection wet samples have to be stored on board in such a way as to preserve them from deterioration that will affect the subsequent analysis of contaminants. Keeping the samples in low temperature (at 4 ºC) and away from light and air (as much as possible) will slow down oxidation and bacterial activity, helping in maintaining sediment's initial characteristics. The first few hours after sampling are the most critical for changes to occur in the sample, therefore preservation steps should be taken, where possible, immediately upon sample collection (HELCOM 2012).

b. Wet sieving

70. Sediment texture may differ among locations, from very fine clay in the open sea to coarse sandy sediments close to the shoreline. Finer sediments indicate net depositional areas, which are preferable sampling stations for studying pollution impact, while coarse sand, pebbles or rocky substrates are not favourable sampling locations. For pollution studies, the most informative fraction of the sediment is the silt and clay fraction (< 63 μm) because contaminants are mainly associated with finer particles (EC 2010, ICES/OSPAR 2018) and coarser sediments (sand fraction) have much lower concentrations of heavy metals and organic contaminants. Therefore, the distribution of contaminant's concentrations in sediments will generally follow the distribution of fine-grained sediments. However, sieving over 63 μm mesh adds another step in the processing of the sample and, consequently, an additional source of potential contamination. Also, sieving over 63 μm mesh may be influenced by the unsuccessful disaggregation of particle conglomerates, which may affect the efficient quantitative segregation of silt + clay from the sand fraction.

71. The IMAP Common Indicator Guidance Fact Sheets (UNEP, 2019) requires the separation of the sediment fraction less than 2 mm, as the appropriate sediment fraction for the determination of heavy metals and organic contaminants. Also, an additional sieving over a 63 μm mesh is requested, in order to record the percentage of the silt and clay fraction in the sediment. This data will be used for normalizing contaminants concentrations in the whole sediment (< 2 mm) for the grain-size effect, evaluating pollution levels and comparing between areas with different sediment texture.

72. Upon arrival on board, sediment samples should be wet sieved using a 2 mm mesh-size sieve as soon as possible in order to remove large detritus and benthic organisms, which may affect the sediment characteristic during subsequent sample handling and processing (storage, freezing or ultrasonic treatment) (EC, 2010).

73. It is preferable to use seawater from the sampling site for wet sieving in order to avoid any possible alteration of the sediment equilibrium (such as adsorption or desorption of metals). If this is not possible, wet sieving could take place in the laboratory using seawater with approximately the same salinity with the sampling location. Sieving over 63 μm mesh, if not implemented on board, it can be done in the laboratory.

74. For heavy metal analysis, sieving for both 2 mm and 63 μm mesh sizes may be carried out using sieves made of polymer (PVC or acrylic rim, with nylon or polyester mesh).

75. For organic contaminants analysis sieving may be carried out using sieves made of stainless steel (rim and mesh).

76. The sediment material is placed on the mesh, water is poured, and the sieve is moved manually. For the processing of larger numbers of samples, sieves may be placed on vibrator tables. Clays often tend to form larger lumps if dried, therefore wet sieving should be done when the sediment is still wet. In case the sediment is becoming dry, it has to be pre-soaked in seawater for at least 2 hours to disaggregate the lumps (EC, 2010). However, this procedure may result in the release of contaminants, which are adsorbed on particles' surface and should be avoided, if possible. In case that pre-soaking is needed, use seawater from the sampling area and sieve disaggregated particles as soon as possible.

77. For heavy metal analysis, the sieved sediment is collected with a plastic spatula and stored in a plastic container for further processing (drying). For organic contaminants analysis the sieved sediment is collected with a stainless-steel spatula and stored in a glass or aluminium container.

c. Drying

78. Prior to the instrumental detection, sediment samples must be dried. For metal (except volatile mercury) analysis, sediments should be freeze-dried, which is the preferable procedure. Alternatively, the sediments may be dried at any temperature below 105°C until constant weight. For mercury analysis, to minimise losses due to evaporation, a sediment sub sample could be air dried at temperature <50°C (EC, 2010).

79. For organic compounds analysis drying procedures depends on the compounds to be analysed. For chlorinated hydrocarbons sediments can be freeze-dried taking care to avoid determinant loss through evaporation by keeping the temperature in the evaporation chamber below 0°C (OSPAR, 2018). For PAH determination, freeze-drying sediment samples may be a source of contamination due to the back-streaming of oil vapours from the rotary vacuum pumps. Furthermore, drying the samples may result in losses of the lower molecular weight, more volatile PAHs through evaporation. To protect sediments samples during freeze drying from cross-contamination from particles and vapours, the sample containers could be covered with a lid or filter paper perforated with a small hole (HELCOM, 2012).

d. Homogenization and storage of dried sediments

80. After drying, the samples are homogenized using a ball mill and are stored in a cool and dark place, for further analysis. Temperature is the most important factor affecting the samples, from the time of sample collection through handling to the final analyses. Also, contamination from the laboratory's air should be avoided.

81. Freeze-dried sediment samples can be stored in pre-cleaned wide-mouth bottles with a screw cap. Samples intended for the analysis of metals can be stored in plastic or glass containers. For mercury analysis, samples must be stored in acid-washed borosilicate glass or quartz containers, as mercury can move through the walls of plastic containers. Samples intended for the analysis of organic contaminants must be stored in amber glass, stainless steel or aluminium containers (EC, 2010).

82. Containers with sediment samples should be archived and kept in storage after the completion of the analysis, in order to be used as a replicate sample in case crosschecking of the results are required or additional determinations are needed in the future. Freeze-dried sediments remaining after analyses could be are stored in the original sample bottle, closed with an airtight lid to protect against

moisture. When stored in a cool, dark place, samples may be archived and stored for 10-15 years (EC, 2010).

Consultation Meeting to Review MED POL Monitoring Activities
Athens, 22-23 November 2011

MANUAL ON SEDIMENT SAMPLING AND ANALYSIS

UNEP/MAP
Athens, 2011

TABLE OF CONTENTS

1. Introduction

Within the Regional Seas Program of UNEP, many scientists are concerned about sediment sampling and analysis and therefore there is an increasing demand for the reliable analysis of both organic and inorganic pollutants in sediments. On the other hand, the sampling strategy set prior to the monitoring activity is critically important and should be established with caution in order to represent the sampling site and achieve the statistical objectives of a trend monitoring programme.

The need for a revision of the trend monitoring programme in sediments was raised during the Second Review Meeting of MEDPOL Phase III Monitoring Activities (Saronida, 2003), after a first examination of the sediment monitoring data was made by an expert, and it was recommended by the meeting to revise the existing strategy (UNEP(DEC)/MED WG.243/4). Afterwards, an expert meeting to revise the strategy for trend monitoring of pollutants in coastal water sediments was organized in April 2005 (Athens) and the meeting report (UNEP(DEC)/MED WG.273/2) considered important recommendations for the revision.

Dr Jean-Pierre Villeneuve (IAEA/MESL) drafted the initial version of the manual aimed at presenting the state-of-the-art in sediment monitoring in coastal waters. It fully took into account the recommendations of the expert meeting on both sampling strategy and analysis. A detailed section on sampling instruments and sample handling is also included in the manual, because it was observed in the training courses organized by MED POL and IAEA/MEL that there is a lack of knowledge on different sampling instruments and the sampling/sample pretreatment techniques. The draft manual was discussed at the Third Review Meeting of MEDPOL Phase III Monitoring Activities (Palermo, December 2005) and further comments of the meeting were incorporated in the present text. The section on normalization procedures was revised by Dr Barak Herut (IOLR, Israel). The section on ^{210}Pb dating was written by Dr. Joan-Albert Sanchez-Cabeza (Universitat Autònoma de Barcelona, Spain).

It is a considerable demand on resources to sample and analyze sediments, so, in order to facilitate the work of the laboratories in charge of monitoring, two different approaches (see the Conclusion) are indicated for sampling, sieving and analyzing the samples: the minimum requirement and the state-of-the-art, then laboratories could use the way that would correspond better to their needs and to their budgets.

2. Sampling design

2.1 Objectives

Sediments have an important role to play in the monitoring of the environment as they are considered as the final sink of most contaminants. Marine sediments are closely inter-related to other compartments of the environment. Therefore, their use in monitoring should be part of an integrated monitoring programme.

By far the most important step in designing of the sampling strategy of the monitoring programmes is the strict definition of the objectives of the programme concerned where the objectives should be put as detailed, specific and quantifiable as possible. To this end, a number of important factors should be taken into account, including the nature of the control measure, the contaminant concerned, the nature and location of the inputs, statistical aspects of sampling and analysis etc.

In addition, a trend monitoring programme should permit statistical comparison of the concentration of contaminants between sites (spatial distribution), highlighting areas with high concentrations of contaminants that are of concern. It is anticipated that a temporal trend monitoring programme for trace metals will at a minimum have 90% power to detect a 5% per year change over a period of between 15 and 20 years.

2.2 Sampling sites

Within MED POL monitoring programmes basically two site typologies are considered: Hot spots and coastal waters. As a matter of definition, coastal zone trend monitoring is done through a network of selected fixed coastal stations, with parameters that contribute to the assessment of trends and the overall quality status of the Mediterranean Sea. This type of monitoring is carried out on a regional basis. Trend monitoring of “hot spot” areas is done at intensively polluted areas and high risk areas where control measures have to be taken. These areas are designated by local authorities according to some common definitions provided by WHO-MED POL.

The definition of hot spots and coastal areas as regards sediment trend monitoring could be specified as follows:

- Hotspots are the most polluted sites as recorded using sediments and all such sites should be monitored (NB: these may not necessarily always be the same as the identified MED POL hot spots)
- Coastal sites are sites mainly located in the near shore coastal waters and a limited number of representative stations should be selected for state assessments.

Both hotspot and coastal areas are suitable for monitoring contaminants’ content in sediments, however, only sedimentary basins with positive accumulation can be considered for monitoring. Coastal areas with sedimentation rates higher than ~5 mm/year are suitable for annual monitoring, whereas areas of lower accumulation rates should be monitored at a lower frequency. Sensitive areas for biological life and protected areas within the near shore coastal waters are also recommended to be included in the monitoring network

2.3 Sampling stations

Sample sites are normally chosen on a broad grid network or transects. It is recommended that at least **three** stations be chosen along the sediment distribution gradient of a selected site to include hot spot and the near-shore coastal area. While doing so, nearby sensitive areas for biological life should also be included in the network.

In an example case, ”O” marks sampling stations in the grid below and “hot spot” station is marked by “Δ”. The arrow is pointing in the direction of the residual current (distances are indicated in nautical miles).

It could be recommended to limit the number of stations for data quality assurance purpose, however, the selected station(s) should be representative for the hot spot and the other area of interest.

It is also recommended to examine the selected site for sedimentary purposes as an initial step of the work in order to identify the sediment structure of the whole area as well as

the sedimentation rates. Fine and regular sedimentation sites are experienced as more favourable for monitoring purposes.

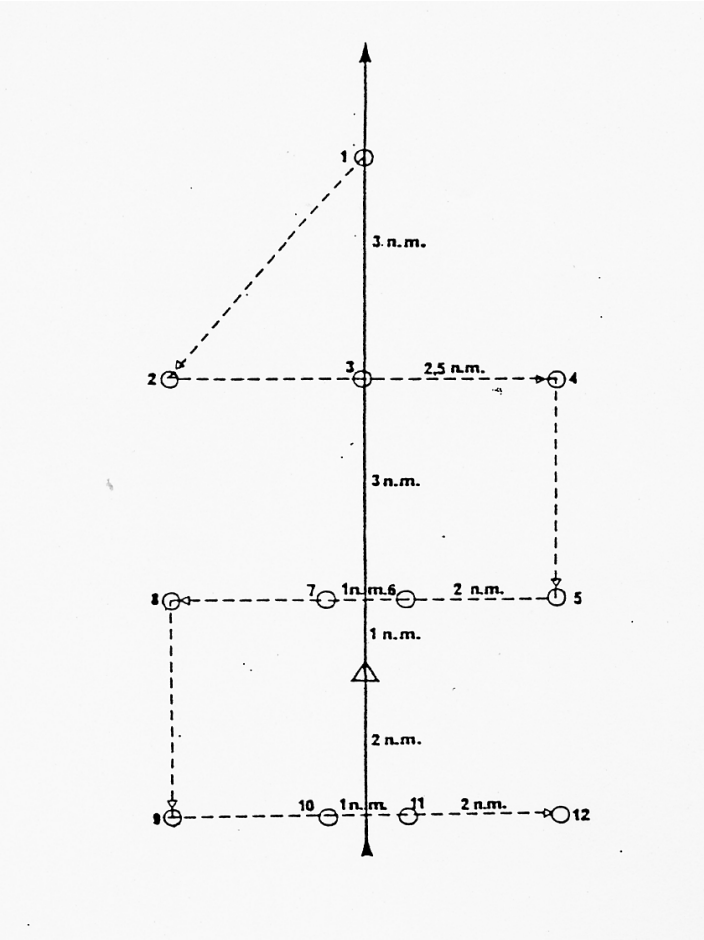

Figure 1: Example case for sampling.

2.4 Number of samples

Multiple samples have to be collected at each station in order to achieve the statistical sensitivity of sampling. It was recommended to take at least **three** samples at each station area (ex: for an area with app. 10 m depth and 10 m radius). In the pilot phase of the programme (first five years) **five** samples for each station is recommended to better understand the sampling variability if it is not known from previous monitoring efforts. Pooling of individual samples is not recommended especially in the pilot phase in order to achieve the field variability, which is an essential parameter for power analysis and trend tests.

2.5 Sampling layer

For spatial trend monitoring at a distribution gradient, surface sediments (uppermost 5 mm) should be sampled both at hot spots and near-shore waters.

For temporal trends, it is recommended to either sample the upper 5 mm at coastal near-shore stations or use core sediments and sample a sediment-depth profile, provided the sedimentation rate is known. However, this will depend on the specific situation.

2.6 Sampling frequency

As a basis and general rule, it is recommended that the sampling frequency is adapted considering the sedimentation rate.

It is generally accepted that for monitoring temporal trends at hotspot stations with high sedimentation rates (>5 mm/year), the sampling frequency can be initially set as annual or more frequent. If the sedimentation conditions are very variable at selected hot spots other frequencies could be adopted. If sampling of deeper layers at near-shore coastal waters is adopted for temporal trends, then sampling frequency could also be reduced according to the accumulation rate at the site. Sampling frequency could also be reduced when parameters are close to or below the quality targets.

In monitoring programmes of seasonal sampling, special attention should be given to sites significantly affected by river sediment input, in which accumulation rates may change seasonally following flood events. Additional attention should be paid to local conditions such as compaction, bioturbation and re-suspension events.

3. Sampling instruments and sample handling

3.1 Sampling instruments

The type of sampling equipment required for sediment surveys is dependent upon the contaminants of interest and on the information requested. Samples of surface sediment taken from a grab can be used to provide an assessment of the present levels of contamination in an area. The use of a more sophisticated sampler, such as a box-corer, would add reliability to the sample, but also would increase the operating cost of the survey. The type of sampler should be chosen among the followings:

Sediment samplers could be divided roughly into 2 different techniques: grab sampling which collects surface and near surface sediments and coring which collects a column of the subsurface sediment and could be required to establish the historical pattern of the contamination. In all grab and core operations, a slow approach to the sea floor should be ensured to avoid the creation of “bow wave” that disturbs the sediment-water interface prior to sampling. In some circumstances, it would be, also, possible to have the samples collected by divers using either glass or Teflon beakers.

3.1.1 Grab sampler

Undisturbed surface sediment samples can provide an immediate assessment of the present levels of contamination in the area in relation to the textural and geo-chemical characteristics of the sediment. The sampler used must consistently collect relatively

undisturbed samples to a required depth below the sediment surface and of sufficient volume to permit subsequent analyses.

The Van Veen grab is among the most commonly used grab samplers. With this bottom sampler, samples can be extracted from any desired depth. While it is being lowered, both levers are locked wide apart whereby the jaws are open. Upon making contact with the waterbed, the locking mechanism is released and when the rope is pulled out to raise the sampler, the jaws close.

The small model (Figure 2), with a surface of 250 cm^2, made of stainless steel has a weight of approximately 5 kg and could be hand-operated from a small vessel. It is not recommended for greater water depth. The main problem with this sampler is that it is sometimes difficult to recover the surface layer of the sediment, so this type of sampler could be used only in case a coring device is not available.

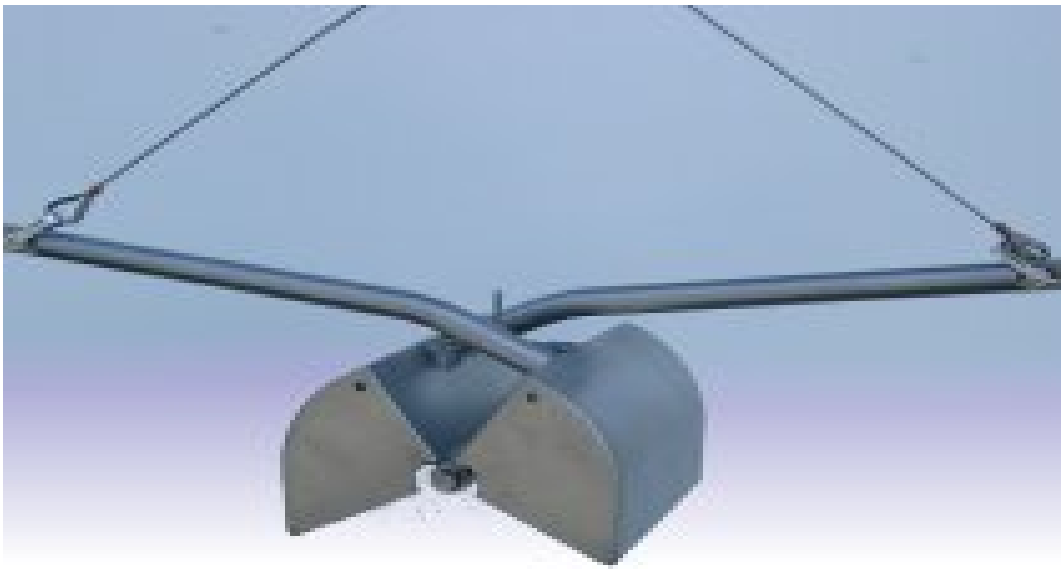

Figure 2: Van Veen grab operated manually (picture from Hydro-Bios, Germany).

There are other models of Van Veen grab, which are winch-operated, with a weight up to 80 kg. These models are presented in the **annex** to this document**.**

3.1.2 Corer

Sediment subsurface samples are often taken using barrel or box corers to determine the change in lithology and chemical composition with depth in order to assess environmental changes in metal fluxes with time. Cores are usually collected in areas of fine-grained sediments but specialized corers are available for coarse-grained sediments.

The main types of corers having cylindrical barrels are the gravity corer (Figure 3) which free-falls from the ship and penetrates the sea floor by gravity, and the piston corer which is released a set distance above the sea floor, penetrates the sediment by free fall, and sucks the sediment into the core barrel by an upward moving piston as the core is retrieved.

Figure 3: Gravity corer (picture from Hydro-Bios, Germany).

For trace metal analysis, plastic core liners are placed inside the core barrels to contain the sediment core sample and to avoid the problems of extrusion and contamination that occur in unlined barrels. When this kind of liner is used, care should be taken for collecting the sample for organic compounds determination, the sample should be collected at the inner part of the core at about a cm from the wall of the plastic liner. In general, the greater the diameter of the liner, the less will be the amount of distortion of the subsurface sediment by the corer penetrating the sediments. Core liners with internal diameters > 50 mm are usually satisfactory for obtaining samples for geochemical purposes.

After the corer is retrieved, the liners are capped at the bottom; the liner is removed from the barrel; the top is capped, and the core stored in a vertical position until all the water inside the liner has risen to the top. The liner is cut off at the sediment - water interface, capped and placed in a deep freezer or a cold room (4°C) for transport to the laboratory. Visual observations and measurements of sediment core samples should include information on the site number and location, depth, time, core length, lithology, stratigraphy, and any distortions in sediment layers.

In the laboratory, core sampling is best carried out by extruding the core upwards and slicing off layers (~ 1 cm) using a non-contaminating cutter (e.g. stainless steel, plexiglass or splitting the plastic core liners lengthwise, avoiding the smeared zone around the inside of the core liners and sampling the interior section of the core.

In order to check the repeatability of the sampling, more than one sediment sample can be collected within the same area. This can be done with the multi-core sampler (Figure 4). After analyzing the different samples, an estimation of the standard deviation due to sampling can be estimated.

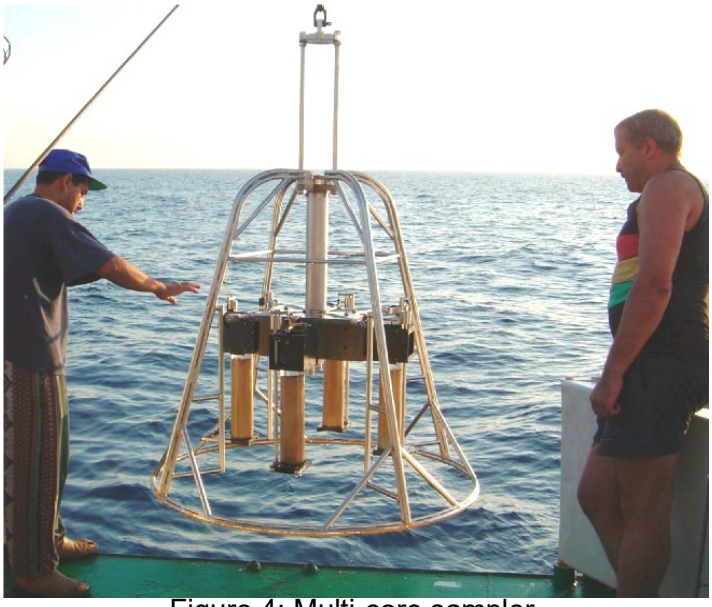

Figure 4: Multi-core sampler.

3.1.3 Box corer

Rectangular sampling devices which obtain cores about 15-25 cm square and 15-60 cm deep are known as box corers (Figure 5) and can be recommended for detailed sampling at or below the sediment-water interface. The advantage of the various types of box or square corers is that they can recover the surface sediment and fauna virtually intact. They can be sub-sampled by inserting several 5 cm diameter tubes into them. However, when sub-sampling is used, the core material should be taken from the mid-part of the core to avoid any “edge effects”. Such samples are treated in the same way as the core samples described above.

Figure 5: Box corer.

3.2 Sample handling

The procedure outlined below assumes that these samples will be collected from a vessel equipped with the basic collection facilities such as a winch, or other such lifting equipment and adequate refrigerated storage space.

Regardless of the equipment chosen for the sampling, it is useful to know the water depth at each station before starting the sampling. The purpose is to ensure adequate cable length for operation of the correct equipment and to control the speed of entry of the sampler into the sediment. The speed of deployment of the sampler can be critical to good operation and sample recovery. It is also useful to have some understanding of the currents at the sampling site. Strong near-bottom currents can lead to poor equipment deployment, deflect a grab sampler, or require a long cable/wire to be deployed. Care should be taken to ensure that the weight of the sampler is adequate for working at the particular current conditions.

On-board, the sediments contained in the grab sampler require attention to ensure that essential components are neither lost nor contaminated through improper handling. The most critical sampling and storage techniques relate to the avoidance of chemical contamination and change in the physico-chemical characteristics of the sediments. Special steps should be taken to minimize contamination of the samples. For trace metal determinations, the use of a stainless steel grab sampler with Teflon coatings on all surfaces that come into contact with sediments, and polyethylene coated lowering cables are highly recommended. All samples should be collected into cleaned plastic (inorganic samples) or glass vials or aluminum containers (organic samples).

The actual collection procedure is quite simple:

i. Prepare all sample containers for organic analysis by cleaning with solvent and heating in oven at 250 °C overnight.

ii. Clean the sediment grab thoroughly with hot soapy water, rinse with tap water. Avoid placing the grab sampler on the open deck, keep in a large plastic or aluminum tub while not in use.

iii. Clean a large sized plastic or aluminum tub depending on the destination of the sample.

iv. Cock the grab sampler.

v. Haul sampler on-board.

vi. Initially, a visual inspection should be made of the sample by means of the small trap doors on top of the grab to ensure that the sample has been collected in an undisturbed state and to determine if there is water on top of the sample. If water is present, it can be siphoned off with a glass tube or slowly drained so as not to wash the sample unduly.

Note : Plastic bags or wide-mouth jars (polypropylene or borosilicate glass) should be used for temporary storage of sediments for trace metal analysis. Prior to their use, containers and glass or plastic parts associated with the sampling equipment should be cleaned with detergent and acid then rinsed with metal-free water. For trace organic analysis samples should be stored in cleaned wide-mouth borosilicate glass or aluminum

containers. The samples should be stored frozen, or at a sufficiently low temperature (~ 4°C) to limit biological and chemical activity. It is recommended that a minimum sub-sample size be 50 grams.

vii. Once the top of the sediment is exposed, visual estimates of grain-size (coarse, medium, fine grained), color, and the relative proportions of the components should be made and recorded. By inserting the appropriate electrodes into the sample, *in situ* measurements can be made, such as pH.

viii. Most fine-grained sediments usually have a thin, dark yellowish brown surface layer resulting from the oxidization of iron compounds at the sediment-water interface. Since in most cases this layer represents the material being deposited at the present time, it should be sampled carefully with a non-contaminating utensil such as a plastic spatula for trace metals determination and a stainless steel one for organic compounds determination. About 10-30 g should be placed in a numbered polyethylene vial for trace metal analysis and in glass or aluminum container for organic analysis, sealed and frozen for transport to the laboratory.

ix. After the surface layer has been sampled, the grab can be opened and an additional sample, representative of the subsurface, can be obtained. Observations of this material should include color and textural characteristics. To ensure a representative sample, about 100 to 200 grams (or even more) should be collected and placed in a numbered vial. The sample should be frozen quickly for return to the laboratory. Larger samples of about 1 kg are required for admixtures of gravel, sand and mud.

x. Store all sediment samples deep-frozen or, at least, under refrigeration (4^{o}C) until they are transported to the laboratory.

3.2.1 Taking part of the sample for analysis

Depending on the analysis required and on the material of the sampler (plastic liner for corer), the collection of sediment should follow an agreed protocol. The main idea being to avoid contact with plastic liner for organic compounds and contact with stainless steel for trace elements analysis.

The distribution of sediment depending on the analysis to be performed is indicated in Figure 6.

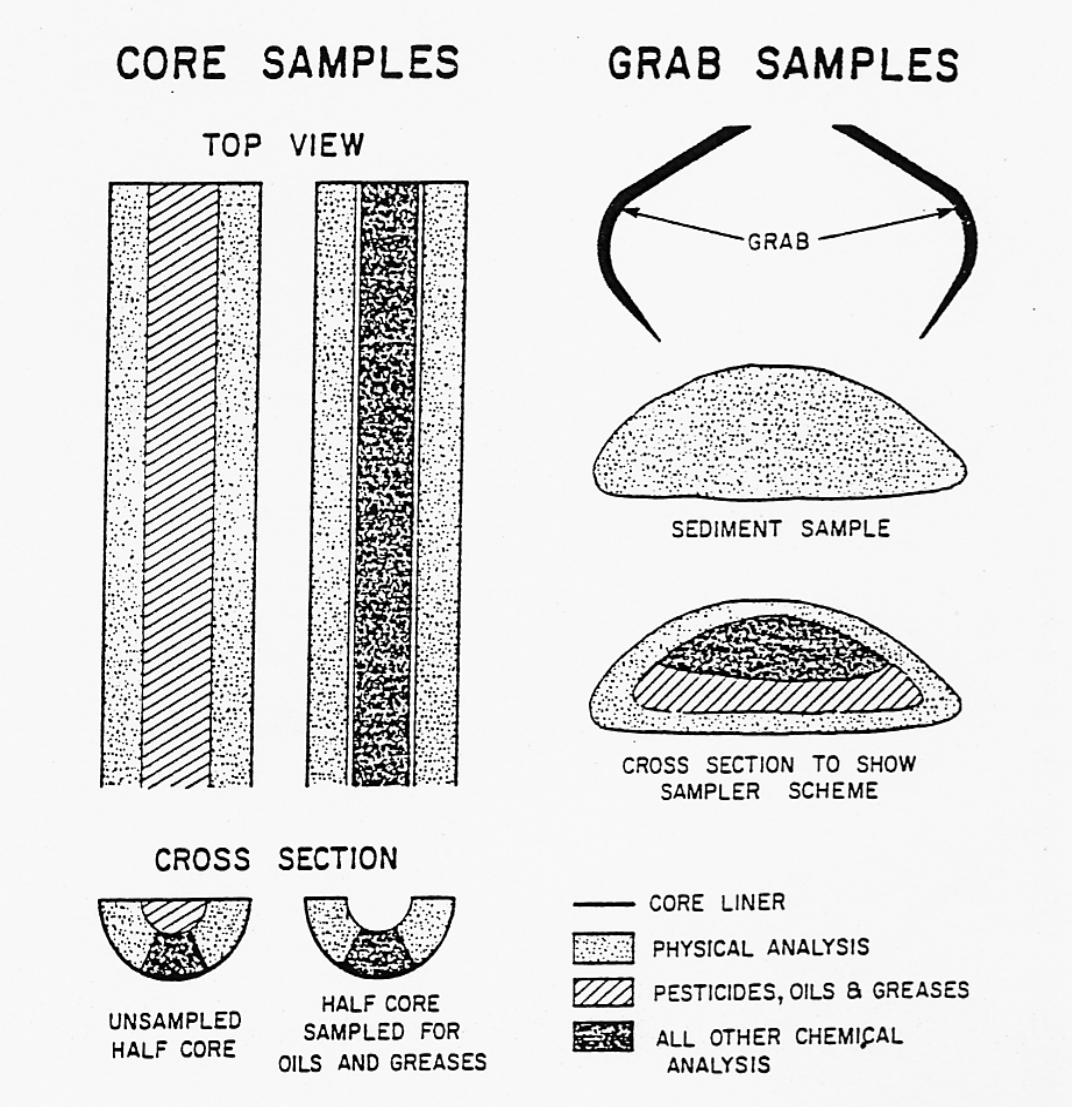

Figure 6: Collection of sediment according to analysis required.

3.2.2 Pre-treatment of the sample

(i) Freeze-drying:

After collection, the sediment samples are transferred into pre-cleaned aluminum boxes or pre-cleaned aluminum paper for organic analysis or into plastic bags for trace element analysis and deep-frozen (or at least kept refrigerated at about 4°C during the transport to the laboratory in order to avoid the bacterial degradation in case of petroleum hydrocarbon analysis).

When in the laboratory, the sediment samples should be deep-frozen at -20°C and, when frozen, freeze-dried in a freeze-dryer. But it is always interesting to archive part of the sample in order to be able to re-analyze it in case of suspected contamination during the analytical process. So, before freeze-drying, one half of the sample should be stored, as such, in the deep-freezer for future reference (in this case it could be interesting to have a -80°C deep-freezer).

In order to proceed with minimal risk of contamination in the freeze-dryer, the samples should be covered with aluminum paper with some pins holes to let the water vapor evacuate and reduce the eventual cross-contamination.

Contamination from the freeze-dryer and from the vacuum pump should be monitored by freeze-drying, with all batch of samples, a portion of clean Florisil. By analyzing the Florisil it is, then, possible to check if the freeze-dryer does not contaminate the samples.

The samples could be weighed before and after freeze-drying in order to access the ratio of dry/wet weight for each sample.

Note: for frozen sample there is no storage limit in time, for freeze-dried samples, if the samples are kept in the **dark**, in a **cool place** (20°C) and with **Teflon tape** around the neck of the bottles to avoid the humidity to enter in the sample, the limit of conservation could be on the order of 10-15 years without deterioration of the sample.

(ii) Sieving:

After freeze-drying the sediment samples could be sieved in order to remove the small gravels, pieces of branches and shells. Before sieving, it is recommended to sort out, with stainless steel forceps (for organic analysis), or with plastic ones (for trace metal analysis), from the sediment sample the small pieces of shells, branches and leaves that could be present in the sample in order to avoid contamination by extra materials. To do that, the samples are transferred to the top sieve of a sieving machine and the machine is activated. Doing so, the sediment will be disaggregated and not crushed.

The question of sieving is very delicate, as many possibilities exist. Some may sieve at 1 or even 2 mm (pre-sieving), only to remove the small pieces of shells, leaves and branches while others may sieve at 250 µm. In most cases, sieving the sediments through a 63 µm sieve in order to separate the silt and clay from the sand and coarser material is both useful and practicable and it is a widely adopted procedure. However, sieving is not recommended for fine and homogeneous sediments, usually found in the zones with high sedimentation rates where the content of the contaminants will be highest because of their wealth of fine particles for which the contaminants have a particular affinity. Obviously, when it is not possible to find fine sediments, sieving can be recommended to extract the finest particles.

Ideally, the sample could be sieved at 63 µm and the two fractions (less than 63 µm and more than 63 µm) could be analyzed. Even in some cases, sieving at 20 µm is undertaken and 3 fractions are, then, analyzed: more than 63 µm, between 20 µm and 63 µm and less than 20 µm.

Since sieving may also cause contamination problems in the samples (basically for the organic contaminants), many steps of sieving should be avoided -if possible- and it may even be recommended to sieve only from 250 µm before organic contaminant analysis.

For spatial trend monitoring sieving is not a critical issue; however, sieving from <1 or <2 mm in the field is recommended to take place directly after sampling or after the freeze-drying step.

For temporal studies sieving is recommended over 63 µm. However, the important thing is to achieve programme consistency and therefore, it is not recommended to switch to

any other fraction if all set criteria in terms of sufficient trend detection are met by a laboratory that is using a whole fraction (e.g. less than 1 or 2 mm) for temporal studies.

A preferable approach is to minimize pre-treatment procedures and unify them for all types of metal/organic analyses and monitoring programmes, both spatial and temporal. Accordingly, sieving to less than 63 µm should be avoided since dry sieving is not reproducible whereas wet sieving is complicated and may introduce the following faults: (i) metal release due to the use of water with different pH and salinity; (ii) mineral (carbonates) dissolution when distilled water is used; (iii) contamination during the sieving and the successive drying.

It is therefore recommended to use one-step dry sieving of the less-than-1 mm fraction in order to perform the analyses on total (bulk) sediment. The rationale for this recommendation is as follows:

(i) Better representation of all relevant size fractions; in some sites coarser fractions (generally, fine and medium sand) are dominant and may contain a significant portion of the total metal (or pollutant).
(ii) Simple to handle.
(iii) Applicable for a wide range of sedimentary provinces and suits a multi-national monitoring programme for the Mediterranean countries.
(iv) Facilitates the use of elemental normalizers (see below).
(v) Avoids potential contamination that might be introduced via wet sieving and successive drying.

(iii) Wet sieving:

Some laboratories use wet sieving techniques. One of the problems that occurs with this technique is the possibility of contamination for organic samples as the material used for this wet sieving method is plastic (silicone tubing and plastic tubes with nylon nets). Another factor that has to be taken into consideration in using the wet sieving technique is the time consumed. The wet sieving method could, however, be used for trace metal work and in well-equipped and staffed laboratories.

Note: If wet sieving is applied, it is recommended to perform it on board using in-situ seawater and thus avoid using in-lab fresh or distilled water in order to prevent metal release and mineral dissolution (see above). However, wet sieving should not be applied on board if there are technical limitations and potential contamination from vessel oils and metal corrosion or from local polluted seawater.

(iv) Archiving:

Archiving sediment (and biota) samples is a must in QA/QC procedures. All samples should be kept for the duration of the monitoring in order to be able to come back to any of them, or to all of them, in case of problems.

Archives should consist of different parts: the first one being the sample wet and deep-frozen as it has been collected. This archive will be used in case of contamination that can appear during the freeze-drying process. So, one part of the original sample can be extracted again, even wet and dried with sodium sulfate, if it appears that the freeze-dryer had contaminated the sample.

Then when the sample has been dried, and an aliquot has been analyzed, the remaining sediment sample should be kept in a glass bottle, with Teflon tape around the closing system (that should be aluminum for organic and plastic for trace metal) to protect against the moisture and then, stored in a cupboard in the dark and cool place. This way, the sample archived can be stored for 10-15 years, so, for the duration of the monitoring program.

4. Normalization factors

4.1 Background

Pollutants tend to be associated with the fine particles of marine sediments due to the relatively higher surface area and the compositional characteristics of the fine particles. Both phyllosilicates and organic matter, which have a chemical affinity to trace elements and organic pollutants, are concentrated in the clay (less than 2 μm) and fine silt (2–20 μm) fractions. Most other minerals, including feldspars and heavy minerals, are found in the fine and coarse (20 - 63 μm) silt fractions, whereas the sand fraction (63 μm – 2 mm) mainly consists of carbonate (calcite, aragonite, dolomite) and/or silica (quartz, opal) minerals. Exceptions to this are coastal sediments of mafic and ultra-mafic terrains.

The metals of considerable environmental impact are As, Pb, Hg, Cd, Zn and Cu. Other metals, such as Mo, Ni, Cr and Co, may reflect anthropogenic input resulting from local quarrying and industrial activities. Anthropogenic Cd and Hg have a stronger affinity to organic matter than to clays, whereas natural Ni and Cr may be related to heavy minerals in certain sedimentological provinces. In order to detect anomalous concentrations of anthropogenic origin it is necessary to normalize the results by a physical or a chemical factor. Some elements may have background concentrations below or near the limit of detection for chemical analysis. Therefore, it has been shown that there is no single normalizing factor that can cope with all pollutant metals in all types of coastal sediments, or even in a single type. Comparing the results to average crust, or upper crust, concentration has been shown to be of limited value for this purpose (Loring and Rantala, 1992; Covelli and Fontolan, 1997) and therefore it is not discussed here.

4.2 Review of normalization methods

4.2.1 Physical normalization

The carbonate and silica mineral groups naturally contain negligible amounts of trace metals and therefore serve as diluents of the marine sediments. Removal of much of those diluents should: a) enhance the analytical capability of detecting low-concentration pollutants; and b) enable comparison between samples on a compositional basis of improved homogeneity. Consequently, choosing the less-than-20 μm or less-than-63 μm fraction for analysis, as mentioned in document UNEP(DEC)MED WG.273/2 (Anavissos meeting report, May 2005), seems like an adequate solution for normalization. Several marine sediment studies of trace elements and their isotopic composition, especially of Nd and Sr, preferred to analyze the less-than-20 μm fraction for geochemical purposes (e.g., Innocent et al., 2000; Krom et al., 2002). However, we are not aware of any such studies for environmental purposes. An essential difficulty in using this size fraction is that it excludes the contribution of trace elements in heavy minerals, and therefore the adequate evaluation of background values. Sieving the less-than-20 μm fraction is also technically problematic since it needs in-lab wet sieving with water of different pH and salinity, consumes more time and hence the

process is more prone to both metal loss from the sample and contamination. Therefore, if physical normalization is adopted, the less-than-63 μm fraction is preferable to the less-than-20 μm fraction for environmental studies, as has been suggested in the Anavissos meeting report (May, 2005), though some of the difficulties remain.

Nevertheless, utilizing physical normalization by wet sieving might suffer from the following disadvantages: a) any sample manipulation is vulnerable to contamination; b) drying the sediment in an oven or freeze drier, a common practice (Loring and Rantala, 1992; Barbanti and Bothner, 1993), is an obstacle for sample desegregation before wet sieving. Ultrasonic treatment is needed in order to facilitate desegregation, which in turn may cause transfer of pollutants from solid to solution (Barbanti and Bothner, 1993); c) in cases of highly variable mineralogical composition, especially in the sand fraction, the normalization would not reflect this variability. Therefore, most environmental studies dealing with polluting metals use the total sample composition, where "total" generally means the less-than-2, or 1 mm fraction (Loring and Rantala, 1992).

An alternative approach for utilizing physical normalization may be applied in areas where preliminary data indicates that all, or almost all, trace elements and pollutants reside in the less-than-63 μm fraction. In such cases the chemical analysis should be performed on a bulk sub-sample whereas grain-size analysis should be performed on another sub-sample. The chemical results are presented after normalization to the less-than-63 μm fraction.

4.2.2 Chemical normalization by a representative element or elements

Chemical normalization has the following advantages: a) a single analytical procedure is practiced for the determination of all required elements, the pollutants and those used for normalization; b) minimal manipulation of the sample minimizes contamination; c) the chosen element, or elements, supposedly normalizes both the grain size and the composition variability.

The element most used for marine sediment normalization is aluminum (Al) since it represents aluminosilicates, the main group of minerals generally found in the fine sediment fractions. Aluminum supposedly: a) derives from detrital minerals, transported from the continent to the sea; b) has negligible anthropogenic input; c) behaves conservatively in normal marine environments. Therefore, Al is expected to normalize for grain-size and for mineralogical variability (Bertine and Goldberg, 1977; Din, 1992; Hanson et al., 1993; Daskalakis and O'Connor, 1995; Covelli and Fontolan, 1997, among others). Another advantage of Al is its easy, precise and accurate chemical determination.

Lithium (Li) has been shown to serve as a better normalizing element than Al in marine sediments enriched with 2:1 phyllosilicates, as in the North Sea where sediments derive from eroded glacier material (Loring, 1990). This element, which generally is not contributed by anthropogenic activity, has been recently found to be superior to Al in a Mediterranean study (Aloupi and Angelidis, 2001) but inferior to Al and to Fe in another Mediterranean study (Covelli and Fontolan, 1997). Loring and Rantala (1992) recommended determining at least Li and/or Al. Rubidium is similar to Li in its geochemical behaviour. As a trace substitute for K it may represent phyllosilicates, feldspars and some heavy minerals and it is not thought to result from anthropogenic activities. It has been used successfully in a few environmental studies in the UK (Allen and Rae, 1987; Grant and Middleton, 1990), but apparently not elsewhere.

Iron (Fe) has been successfully used for normalization in several studies (Rule, 1986; Sinex and Wright, 1988; Blomquist et al., 1992; Herut et al., 1993; Daskalakis and O'Connor, 1995; Schiff and Weissberg, 1999). However, it has been suggested that remobilization and

precipitation can lead to changes in the pollutant/Fe ratio in anoxic sediments (Schiff and Weissberg, 1999). The latter are hardly expected to be found in Mediterranean sediments of open coasts.

A few studies used scandium (Grousset et al., 1995; Ackerman, 1980) and cesium (Ackerman, 1980), or also cerium, beryllium and europium (Herut et al., 1997), as the normalizing element. Since each of these elements may cause analytical difficulties, they are currently not recommended to be used on a routine basis.

4.2.3 Modes of chemical normalization

Chemical normalization by an element is to be performed by one of the following methods:

(i) By comparing the samples, suspected to be polluted, to nearby non-polluted samples of similar texture, mineralogical and major chemical composition. Background concentrations of the non-polluted samples can be established from surface sediments of other regions or from deep core samples of the same region, below the level of anthropogenic intervention. The potential pollutant concentrations should be compared with background averages in order to calculate the enrichment factor (EF) as follows:

$$(1) \quad EF = \frac{X(s)/N(s)}{X(b)/N(b)}$$

where X is the element and N the chemical normalizer (e.g. Al/Fe/Li) concentration; (s) is the sample; (b) is the background value. The evaluation of the EF value taken for estimating pollution should consider both natural variability and analytical errors (especially if the background concentrations were determined in/by another laboratory and/or analytical device).

(ii) By comparing the measured pollutant and chemical normalizers (or multi-element normalizers, Herut and Sandler, 2007) to their relationships in non-polluted (background) sediments, which have a linear relationship at the 95% confidence level, or better, and a high significance ($P<0.001$). The regression equation should follow either $\mathbf{y = ax}$ (x is the normalizing element) or $\mathbf{y = ax + b}$ (Loring and Rantala, 1992; Herut et al., 1995; Covelli and Fontolan, 1997; Roach, 2005). An estimate of the anthropogenic fraction and the ratio between the measured and predicted values (y) can be defined, where the predicted value is within the range of $1 \pm 2\sigma$.

(iii) By calculating the regression line between contaminant and normalizer through a pivot point, which is the concentration of both elements in a non-polluted sand fraction (Kersten and Smedes, 2002) of a selected standard sediment composition. This approach has been adopted by OSPAR (OSPAR/JAMP, 2002; OSPAR, 2005) and is presented in detail in Herut and Sandler (2007).

In summary - Aluminum (Al) and total organic carbon (TOC) determinations should be obligatory. If possible, the determination of Fe and Li as additional normalizers is recommended in order to better assess basin-wide spatial and temporal trends. The most practical normalization approach for the Mediterranean at this stage is the use of the linear regression equations.

The lack of standardized datasets for the Mediterranean prevents defining ‘pivot values’ and the use of the OSPAR chemical normalization approach. It is recommended that a standard analysis be performed for the areas to be monitored including: i) grain-size distribution in order to obtain the relations between physical and chemical normalizers; ii) heavy metal concentration in natural non-contaminated sand fraction; iii) mapping the chemical normalizers (Al, Fe, Li, TOC) range for selecting the proper standard sediment composition; iv) assessment of errors associated with the normalization approach.

4.3 Particle size analysis

Particle size analysis may be performed in order to better characterize the sediment nature and the sedimentological regime of the region monitored. The methods for fractionation into grain size can be found in UNEP/IOC/IAEA (1995) and in Loring and Rantala (1992).

The most time-efficient and robust way to obtain particle size analyses is by a laser-diffraction analyzer. There are many laser-diffraction analyzers on the market, such as the Malvern Mastersizer, the Coulter LS Particle Size Analyzer, or the Microtrac S3500 Analyzer. Laser diffraction is used to detect particle sizes in the range of ~ 0.1 to 2000 µm equivalent spherical diameter (depending on the instrument) using light scattering theory. The refractive and absorption indices for the material must be known for accurate measurements to be made.

Laboratories in which continuous grain-size counters (e.g. Mastersizer) are not available should follow Figure 6. The grain size distribution below 63 µm is determined by one of the sedimentation methods.

Sedimentation methods are based on the application of Stokes' Law, which describes the terminal velocity for an isolated sphere settling in a viscous liquid under the influence of an accelerating force such as gravity. Sedimentation techniques can be cumulative or incremental. In the cumulative method, the rate at which the particles settle is determined, typically, by weighing the mass of settled particles at a certain depth over time. In the incremental method, the change in concentration or density of the material with time is measured at known depths, typically using optical or X-ray sensing. Sedimentation methods are best suited to particles in the range 2-50 µm and, therefore, may not be appropriate for bulk sediment. Temperature must be accurately controlled in order to keep viscosity constant. Incremental sedimentation techniques can be carried out using instruments such as the X-ray SediGraph, manufactured by Micrometrics.

Laboratories equipped with continuous grain-size counters should dry sieve a freeze-dried sub-sample according to the instrumental analytical range (old instruments – below 250 µm; new – below 1 or 2 mm).

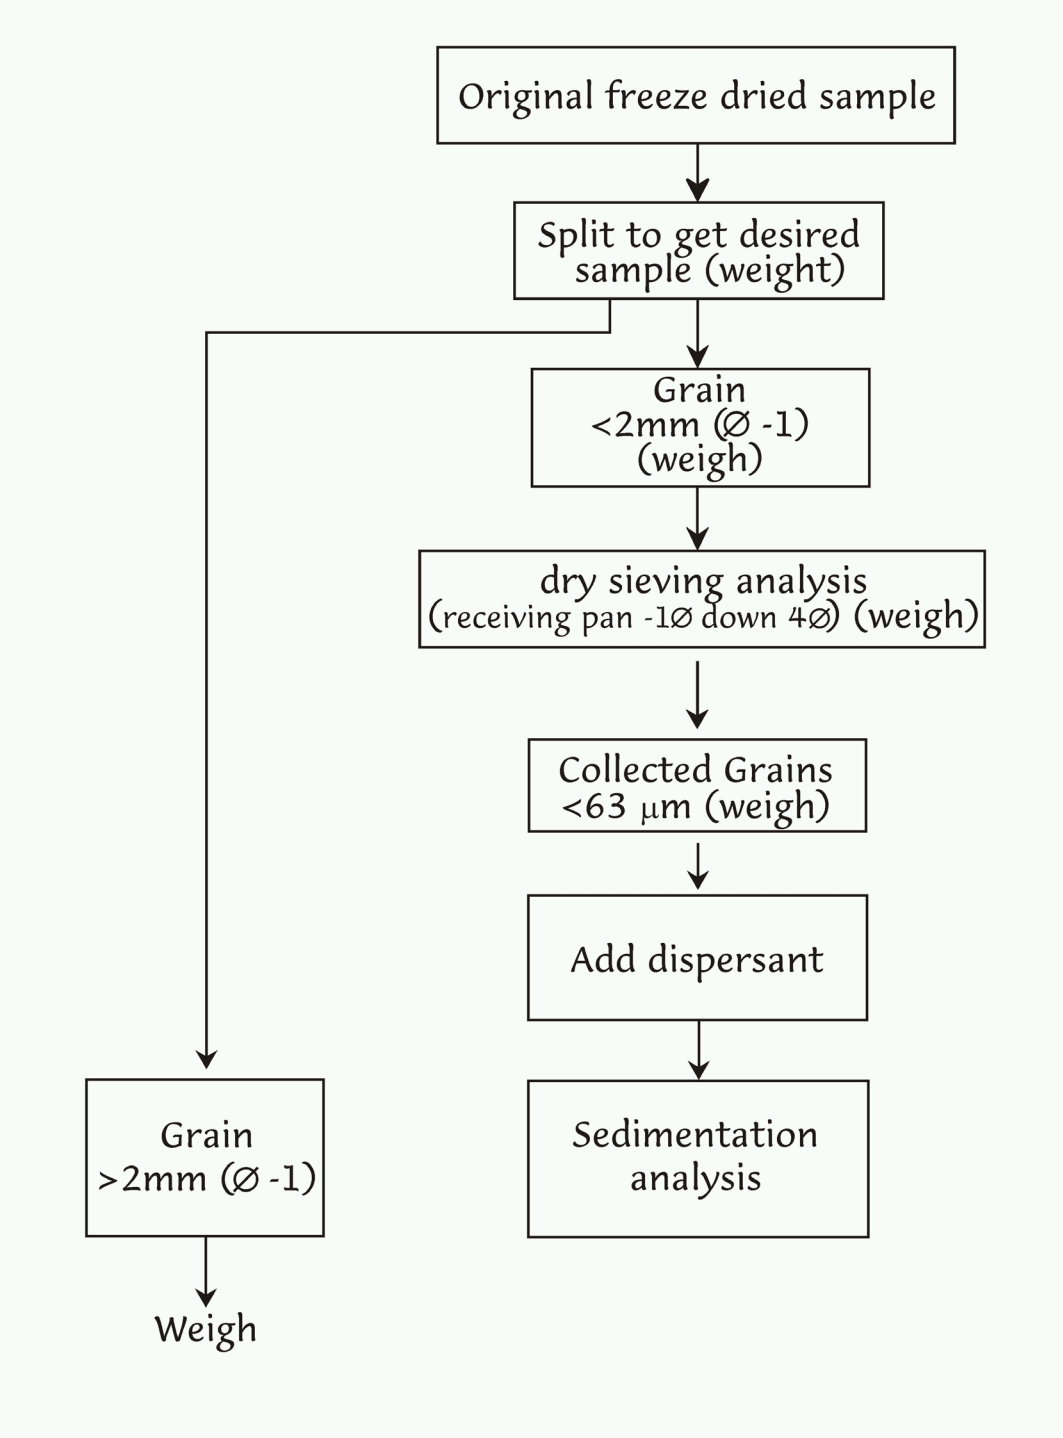

Figure 7: Sequence of steps for the grain size separation of a sediment sample (Please note that 2 mm grain size stands also for 1 mm).

4.4 Total Inorganic Carbon (TIC) and Total Organic Carbon (TOC)

Organic material interacts strongly with both organic and inorganic contaminants. The organic carbon is one of the measures of the organic material. Another parameter would be the determination of lipids, or lipid-like material. The measurement of the hexane extractable organic matter (or HEOM) is also a normalising variable.

The carbonate content (inorganic carbon) of the sediment is generally considered as a dilution factor of the main phases carrying the contaminants and should, also be determined.

Total inorganic carbon (or carbonates) are obtained by the difference of data:

$$TIC\ (\%) = TC\ (\%) – TOC\ (\%)$$

(i) Preparation of samples

Samples for TC analysis are weighed (mg) in tin boats and directly analysed. Samples for TOC analysis are weighed (mg) in tin capsules and acidified with H_2PO_4 1M until the inorganic carbon is removed (3 times in 8 hours intervals to the oven at 55°C). Tin boats and capsules are folded and pressed before the analysis.

(ii) Procedure

Analyses could be done with automatic analyser (such as Elementar “VARIO EL” Instrument) in CN mode. For the mass determination of C and N, an oxidation of the sample followed by the reduction of nitroxides is realized, coupled to chromatographic glass column separation and thermal conductivity detection for CO_2 and N_2.

Note: In case a CHN analyser is available and used for the TC-TOC analysis, Total Nitrogen and Total Organic Nitrogen can be measured simultaneously which can provide a general insight of the lability of organic matter, simply based on the C/N ratio.

(iii) Quality control

Acetanilide standard (C_8H_9NO) is used as a correction factor for accurate and precise measurements (71.1 % C and 10.4 % N) and to control instrumental stability.

The precision of TOC and TC measurements in the samples depends in numerous random factors such as: weighing, use of an acidification step, sample structure (i.e. matrix), concentrations, as well as the instrumental noise. Coefficients of variation (% RSD) must be calculated for each pair of determination, specially, for TOC analysis, which includes an acidification step.

Alternative method to estimate Organic Material in case a CHN Analyser is not available:

The Organic Matter (OM) content in sediments can be measured with the following method:

a) Put the (wet) sediment sample in oven at 60°C for 24 hours (up to constant weight).
b) Weight approximately 1 g of dry sediment (precision 0.01 mg) in a small porcelain boat.
c) Put the sediment for ignition into a furnace at 450°C for 3 hours.
d) Weight the sediment after ignition (precision 0.01 mg).

The Organic Matter (OM) content is equivalent to the percentage of Loss of Weight (LOI %)

$$LOI\ \% = (W_{dry} - W_{ign}) \times 100 / W_{dry}$$

Where:

LOI % = Loss on Ignition (equivalent to the total Organic Matter)
W_{ign} = Weight after ignition
W_{dry} = Weight of dry sediment before ignition

5. Analytical techniques for organic compounds

Before proceeding to the analysis, an aliquot will be taken from the bulk sample and in order to be sure that what is analyzed is representative of the collected sample, the sediment sample should be well homogenized. This could be done in a specialized laboratory homogenizer, but it could be done, more simply, with a spatula, taking care of mixing well the sediment sample before collecting the 10 g aliquot (for organic) or the 1-2 g aliquot (for trace metal) for the extraction.

The analytical part can be found in the Reference Methods for Marine Pollution Studies published by UNEP. All these Reference Methods are available, free of charge, from IAEA-MEL/MESL.

With a set (one for 10 samples, as a minimal requirement) of sediment samples extracted, sediment Reference Material should be extracted to check the quality of the data produced (UNEP/IOC/IAEA/FAO, 1990).

5.1 Chlorinated pesticides and PCBs.

The analytical method for chlorinated pesticides and PCBs in sediment samples, can be found in UNEP/IOC/IAEA, 1996.

5.2 Petroleum hydrocarbons.

The analytical method for petroleum hydrocarbons can be found in UNEP/IOC/IAEA, 1992.

5.3 Organophosphorus pesticides

The analytical method for organophosphorus pesticides in sediment samples can be found in UNEP/FAO/IOC/IAEA, 1997.

6. Analytical techniques for trace metals

For trace elements, in general, the analytical methods can be found in UNEP/IOC/IAEA, 1995.

For mercury: in UNEP/IAEA, 1985 and UNEP/IOC/IAEA, 1985.

7. Sediment radiochronology with ^{210}Pb

One of the main objectives of surface sediment monitoring is to obtain time series that allow to derive the presence or absence of temporal trends due to anthropogenic pressure. However, monitoring programmes are often not long enough to produce valid assessments. Sediments integrate pollution signals and dated sediment cores may provide a reliable record of pollution levels (e.g. Sanchez-Cabeza and Druffel, 2009). Although radiocarbon is used to study impacts extending back millennia, the most suitable tracer for pollution studies is ^{210}Pb because its half-life (22.23 y) allows suitable dating for the last 100 years, when most of the anthropogenic impact has occurred.

^{210}Pb is a natural radionuclide of the ^{238}U radioactive chain with a half-life of $T_{1/2}$ = 22.23 $\pm$ 0.12 yr (DDEP, 2010). It is commonly assumed that *supported* ^{210}Pb in old (> 150 yr) sediments is in equilibrium with its parent radionuclide ^{226}Ra. In recent sediments, ^{210}Pb in disequilibrium with ^{226}Ra is named *excess* (or *unsupported*) ^{210}Pb (^{210}Pb$_{ex}$). The total ^{210}Pb concentration in sediments is usually measured i) by gamma spectrometry (46.5 keV line; Schelske et al., 1994), or ii) alpha spectrometry, through its daughter radionuclide when equilibrium is guaranteed (Sanchez-Cabeza et al., 1998). ^{226}Ra (supported ^{210}Pb) is usually determined by i) gamma spectrometry (352 keV line of ^{214}Pb in equilibrium) or ii) liquid scintillation (Sanchez-Cabeza et al., 2010). If the full ^{226}Ra profile is not available, a mean ^{226}Ra concentration can be i) computed as the mean ^{210}Pb in the core bottom if at least 3 sections show an approximately constant concentration, within the measuring uncertainty (Binford, 1990) or ii) estimated by extrapolation of ^{210}Pb in the bottom sections if the profile shows there an exponential behaviour. Then, $^{210}Pb_{ex} = {}^{210}Pb - {}^{226}Ra$.

The use of ^{210}Pb$_{ex}$ to date sediment cores has been used in a large variety of studies. Since ^{210}Pb was first used to date ice cores (Goldberg, 1963), several authors have developed models that adapt to different sedimentary conditions. These models, used to date undisturbed sediments, can be deduced from a single fundamental equation (Krishnaswamy et al., 1971), which relates excess ^{210}Pb$_{ex}$ concentration in sediment, its flux to the sediment surface and mass accumulation rate.

7.1. Basic information

^{210}Pb$_{ex}$ decays following the radioactive decay law. If both the sediment accumulation and the ^{210}Pb$_{ex}$ flux to the sediment surface were constant, and there were no processes that redistribute ^{210}Pb$_{ex}$ in the sediment, the profile of the ^{210}Pb$_{ex}$ concentration along the core should be a pure exponential curve (Figure 8). These conditions are not commonly met, but the described models allow obtain good dates in many cases. Some needed physical constants and sampling details are:

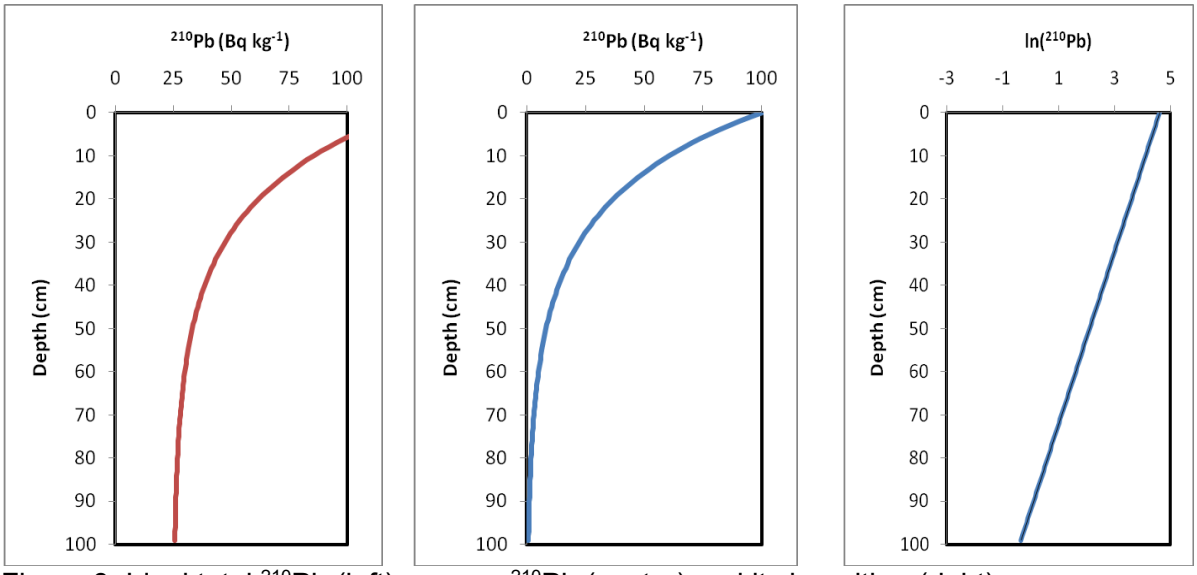

Figure 8. Ideal total ^{210}Pb (left), excess ^{210}Pb (centre) and its logarithm (right).

$T_{1/2} = 22.23 \pm 0.12\ yr$ (DDEP, 2010): ^{210}Pb half-life (yr)

$\lambda = 0.03118 \pm 0.00017\ yr^{-1}$: ^{210}Pb disintegration constant (yr^{-1})

$T(0)$: sampling date (A.D.)

φ : internal core diameter (m)

S : core cross-section (m^2), calculated as $S = \pi\left(\frac{\varphi}{2}\right)^2$.

As different models use similar quantities and constants, a unified notation has been proposed (Sanchez-Cabeza and Ruiz-Fernandez, in press). For example, C_i is the ^{210}Pb$_{ex}$ mean concentration of section *i*, assigned to the geometric centre of the section. Then C_1 is the top section and C_2 is the section below. In the Constant Flux (CF) model, equations refer to quantities in infinitesimal layers *(i)*, derived from calculation. We use *(i)* to refer to the consecutive number of the surface cut (layer) when sampling. For example, *(0)* refers to the core surface and *(1)* to the first surface cut below the surface (usually of the order of 1 cm). For brevity, we define only quantities referred to either sections or layers (usually, section quantities are computed as means of layer quantities). To take into account sediment compaction dating must be performed as a function of mass depth *m* (kg m^{-2}) and not depth *z* (m):

- *z(i)* : depth of layer *(i)* (m), experimentally determined. Note that *z(0)=0* m.
- Δz_i : width of section *i* (m), where $\Delta z_i = z(i) - z(i-1)$
- Δm_i : dry mass of section *i* (kg), experimentally determined
- *m(i)*: mass depth of layer *(i)* (kg m^{-2}), where $m(i) = \sum_{j=1}^{j=i} \frac{\Delta m_j}{S}$.

If we only know the section dry bulk densities ρ_j (kg m^{-3}), the mass depths *m(i)* can also be calculated as $m(i) = \sum_{j=1}^{j=i} \rho_j \Delta z_j$. The mean dry bulk density of section *j* is easily computed as $\rho_j = \frac{\Delta m_j}{S\,\Delta z_j}$.

Some time related quantities are:

- $t(i)$: time elapsed since formation of layer *(i)* (yr). Note that *t(0) = 0* yr
- $T(i)$: calendar age of layer *(i)* (A.D.), which is calculated as $T(i) = T(0) - t(i)$.

The CF model refers to ^{210}Pb deposits (or activity per unit area):

- ΔA_i : $^{210}Pb_{ex}$ deposit in section *i* (Bq m^{-2}), computed as $\Delta A_i = \frac{C_i\,\Delta m_i}{S}$
- *A(i)* : accumulated deposit below layer *(i)* (Bq m^{-2}), computed as $A(i) = \sum_{j=i+1}^{j=\infty} \Delta A_j$
- *I = A(0)* : core $^{210}Pb_{ex}$ inventory (Bq m^{-2})

There is a large variety of definitions that describe sedimentation rates (linear or massic). The following are recommended:

- *s* : sediment accumulation rate – SAR (m yr^{-1}).
- *r* : mass accumulation rate – MAR (kg m^{-2} yr^{-1}). Sediment and mass accumulation rates (SAR and MAR) are proportional: $r = s \cdot \rho$

When a sediment layer *(i)* is formed, the $^{210}Pb_{ex}$ incorporated can be calculated as (Krishnaswamy et al., 1971):

$$C(i, t=0) = \frac{f(i)}{r(i)} \qquad (1)$$

This is the basic expression on which the dating models are based. If MAR increases, the concentration decreases and the ^{210}Pb signal is diluted. If MAR decreases, the concentration increases and the ^{210}Pb signal is enriched. Therefore, $^{210}Pb_{ex}$ profiles are not pure exponential functions when accumulation rates are variable.

7.2. Dating models

Dating models are used to i) obtain the section/layer age as a function of depth (*t*), ii) calculate accumulation rates (*s, r*) and iii) estimate sediment mixing rates (not reviewed here). The models have been recently reviewed by Sanchez-Cabeza and Ruiz-Fernandez (in press) and the more useful and commonly used models are described here.

7.2.1. Constant Flux and Sedimentation model (CFCS)

It is recommended that the dating experiment starts with the use of this model, commonly used in the literature to estimate mean accumulation rates. The Constant Flux and Constant Sedimentation model (CFCS; Crozaz et al., 1964; Krishnaswamy et al., 1971; Koide et al., 1973; Brugam, 1978; Appleby and Oldfield, 1983) is based on two hypotheses, (i) that the flux to the sediment surface (*f*) is constant and that the mass accumulation rate (*r*) is constant. In these conditions equation 1 leads to:

$$\frac{f}{r} = C_0 \qquad (2)$$

The decay of ^{210}Pb as a function of time (and hence time) allows us to deduce the CFCS equation:

$$C_i = C_0 \, e^{-\lambda m_i / r} \qquad (3)$$

This equation indicates that, when the CFCS hypotheses are met, a purely exponential decrease of C_i with depth should be observed (Figure 1, centre). This can be easily assessed by plotting the $^{210}Pb_{ex}$ profile in a logarithmic scale as a function of the MAR (Figure 1, right), and then perform a linear regression between (Crozaz et al., 1964) the logarithm of $^{210}Pb_{ex}$ concentration (ln C_i) and the mass depth m_i:

$$\ln C_i = \ln C_0 - \frac{\lambda}{r} m_i \qquad (4)$$

From the regression line equation obtained with a spreadsheet ($y = a + bx$) the intercept is $a = \ln C_0$ and the slope is $b = -\lambda / r$, then we can calculate $C_0 = e^a$ and, more importantly, $r = -\lambda / b$. From the regression uncertainties of *a* and *b* the uncertainties of C_0 and *r* can be easily derived. When the CFCS hypotheses are met, the purely exponential behavior of C_i *vs.* m_i allows to estimate ages. From the derived MAR, and assuming that *t(0) = 0 yr*, the age *t(i)* can easily be derived from $t_i = T(0) + \frac{m_i}{r}$. When the profile is piecewise linear, showing two or more linear segments (Goldberg et al., 1977; Brugam, 1978), we may derive mean MAR for each segment.

7.2.2. Constant Flux model (CF)

The Constant Flux model (CF; Robbins, 1978; Smith and Walton, 1980; Appleby and Oldfield, 1983; Binford, 1990; Carroll and Lerche, 2003) is widely known as the Constant Rate of Supply model (CRS; Goldberg, 1963; Crozaz et al., 1964; Krishnaswamy et al., 1971; Appleby and Oldfield, 1978; Appleby, 2001 and 2008; Sanchez-Cabeza et al., 2000). The fundamental hypothesis is that the $^{210}Pb_{ex}$ flux to the sediment surface is constant (*f*). The age of layer *(i)* can be calculated as:

$$t(i) = \frac{1}{\lambda} \ln \frac{A(0)}{A(i)} \qquad (5)$$

where *A(i)* is the $^{210}Pb_{ex}$ accumulated deposit below layer *(i)* and that, therefore, *t(i)* is the age of the infinitesimal layer *(i)*, not of a section. The mean age of a section, can be estimated as

the mean of its upper and lower layers. *A(0)* is the $^{210}Pb_{ex}$ core inventory and the $^{210}Pb_{ex}$ flux to the sediment surface is $f = \lambda A(0)$.

Garcia-Orellana et al. (2006a) evaluated the ^{210}Pb annual atmospheric flux to the Western Mediterranean from the analysis of 12 soil cores collected from coastal and island sites. The ^{210}Pb fluxes ranged from 34 ± 3 to 121 ± 12 Bq m^{-2} yr^{-1}, with an average of 75 Bq m^{-2} yr^{-1}, and were strongly correlated (R^2 = 0.95) with mean annual rainfall. These results can be used to assess the degree of $^{210}Pb_{ex}$ (and therefore fine particles) focussing in a particular area. In general, $^{210}Pb_{ex}$ inventories should be similar or higher than the expected atmospheric flux. Inventories below the expected atmospheric flux could indicate an incomplete inventory, due to erosion or removal of part of the sedimentary column by sedimentary events. Specific studies could be carried out to determine this value in specific regions (e.g. Sanchez-Cabeza et al., 2007).

The MAR can be calculated as:

$$r(i) = \frac{\lambda A(i)}{C(i)} \qquad (6)$$

and then $s = r/\rho$. Mean section values can be calculated as the mean of their upper and lower layers.

7.2.3. Incomplete inventory

The use of the CF model requires the knowledge of the core $^{210}Pb_{ex}$ inventory, but this is sometimes not possible. The most common case is when the core length is too short and the ^{210}Pb profile does not reach the base value. In these cases it is recommended to use the CFCS model to obtain mean accumulation rates in the sampled segment and to estimate the missing inventory below layer *(j)* as (Appleby, 1998) $A(j) = \frac{r.C(j)}{\lambda}$. Then, one can calculate the inventory from the accumulated deposit to the incomplete core bottom ($\delta(A)$) and then the total inventory is $A(0) = \delta A + A(j)$. With this value we can now use the CF model described above.

Alternatively, if a reference date *(t)* is known to happen at layer *(i)*, we can calculate the inventory below that layer as $A(j) = \frac{\delta A}{e^{\lambda t} - 1}$ and then we can proceed as before (Appleby, 1998).

7.2.4. Mixed sediments

The main hypothesis of sediment dating is that the system is closed. This requires that $^{210}Pb_{ex}$ is not affected by redistribution processes. Mixed sediments do not provide useful information for reconstruction studies, although some information on mean accumulation rates below the mixed segment and other geochemical properties may be obtained.

The mixed segment (sometimes named SML, Single Mixed Layer) can be easily identified by the presence of an approximately constant ^{210}Pb activity (Figure 9). Below the mixed segment, the profile usually decreases exponentially and, therefore, the CFCS model can be used to derive MAR and SAR. Although some authors also use the CF model below

the mixed segment, caution must be taken as, assuming that mixing is the result of a continuous process, the apparent time span of the mixed segment should be taken into consideration when estimating age uncertainties. If a quadratic propagation scheme is used, any age will have an uncertainty larger that the time span covered by the mixed segment and, therefore, its utility will be compromised. Mixed sediments should only be used to estimate mean accumulation rates.

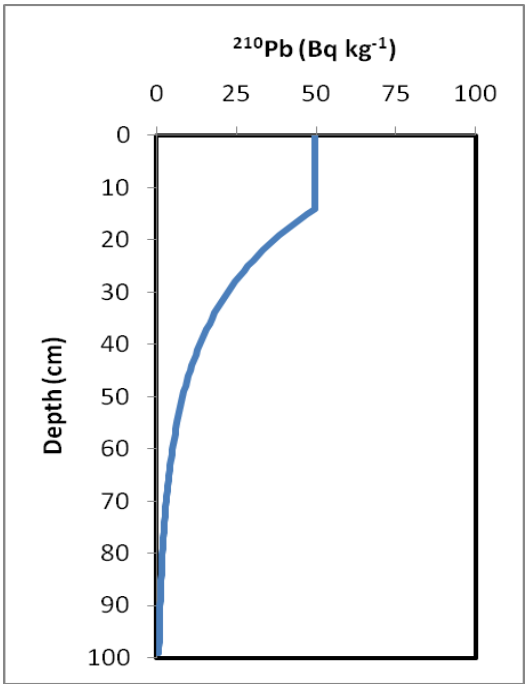

Figure 9. Mixed sediment. Notice the constant ^{210}Pb concentration at the surface.

7.3. Age model validation

The models shown are robust and have been successfully used many times. However, the complexity of most real situations (and particularly marine environments) is such that none of the models can be assumed appropriate without validation (Schottler and Engstrom, 2006). Traditionally, some global fallout radionuclides such as ^{137}Cs, ^{239,240}Pu and ^{241}Am are used. These three radionuclides should show a 1963 time mark in undisturbed sediments, corresponding to its maximum tropospheric concentration, and ^{137}Cs may reflect an additional time mark in 1986 due to the Chernobyl accident (e.g. Sanchez-Cabeza et al., 1999). Other time markers can be used to validate the age models, including for example:

- Volcanic eruptions may leave ash layers deposited in very short periods (Arnaud et al., 2006).
- Extreme events, such as floods, earthquakes and tsunamis, may leave distinct sedimentary deposits identified as abrupt changes of accumulation rates and various geochemical signatures (van den Bergh et al., 2003; Tuttle et al., 2004; Garcia-Orellana et al., 2006b).
- Changes in the type of accumulated particles (due to changes in land use, fires or other major catchment events) may be revealed by magnetostratigraphy (Oldfield and Appleby, 1984).
- The change in quantity and type of pollen grains may be related to changes in soil use in the catchment areas (Clark and Patt, 1984).

- Abrupt changes in known pollution sources (such as the opening or closure of a large industry) may be identified in polluted areas (Palanques et al., 1998; Diaz-Asencio et al., 2009).

7.4. Suggested procedure

If the $^{210}Pb_{ex}$ profile shows one or more exponential segments (linear segments in a logarithmic plot), mean MAR and SAR for each segment can be estimated by using the CFCS model. Although ages could also be estimated from MAR, the most realistic ^{210}Pb dating model is the CF model and is the one recommended to derive layer (and/or section) ages.

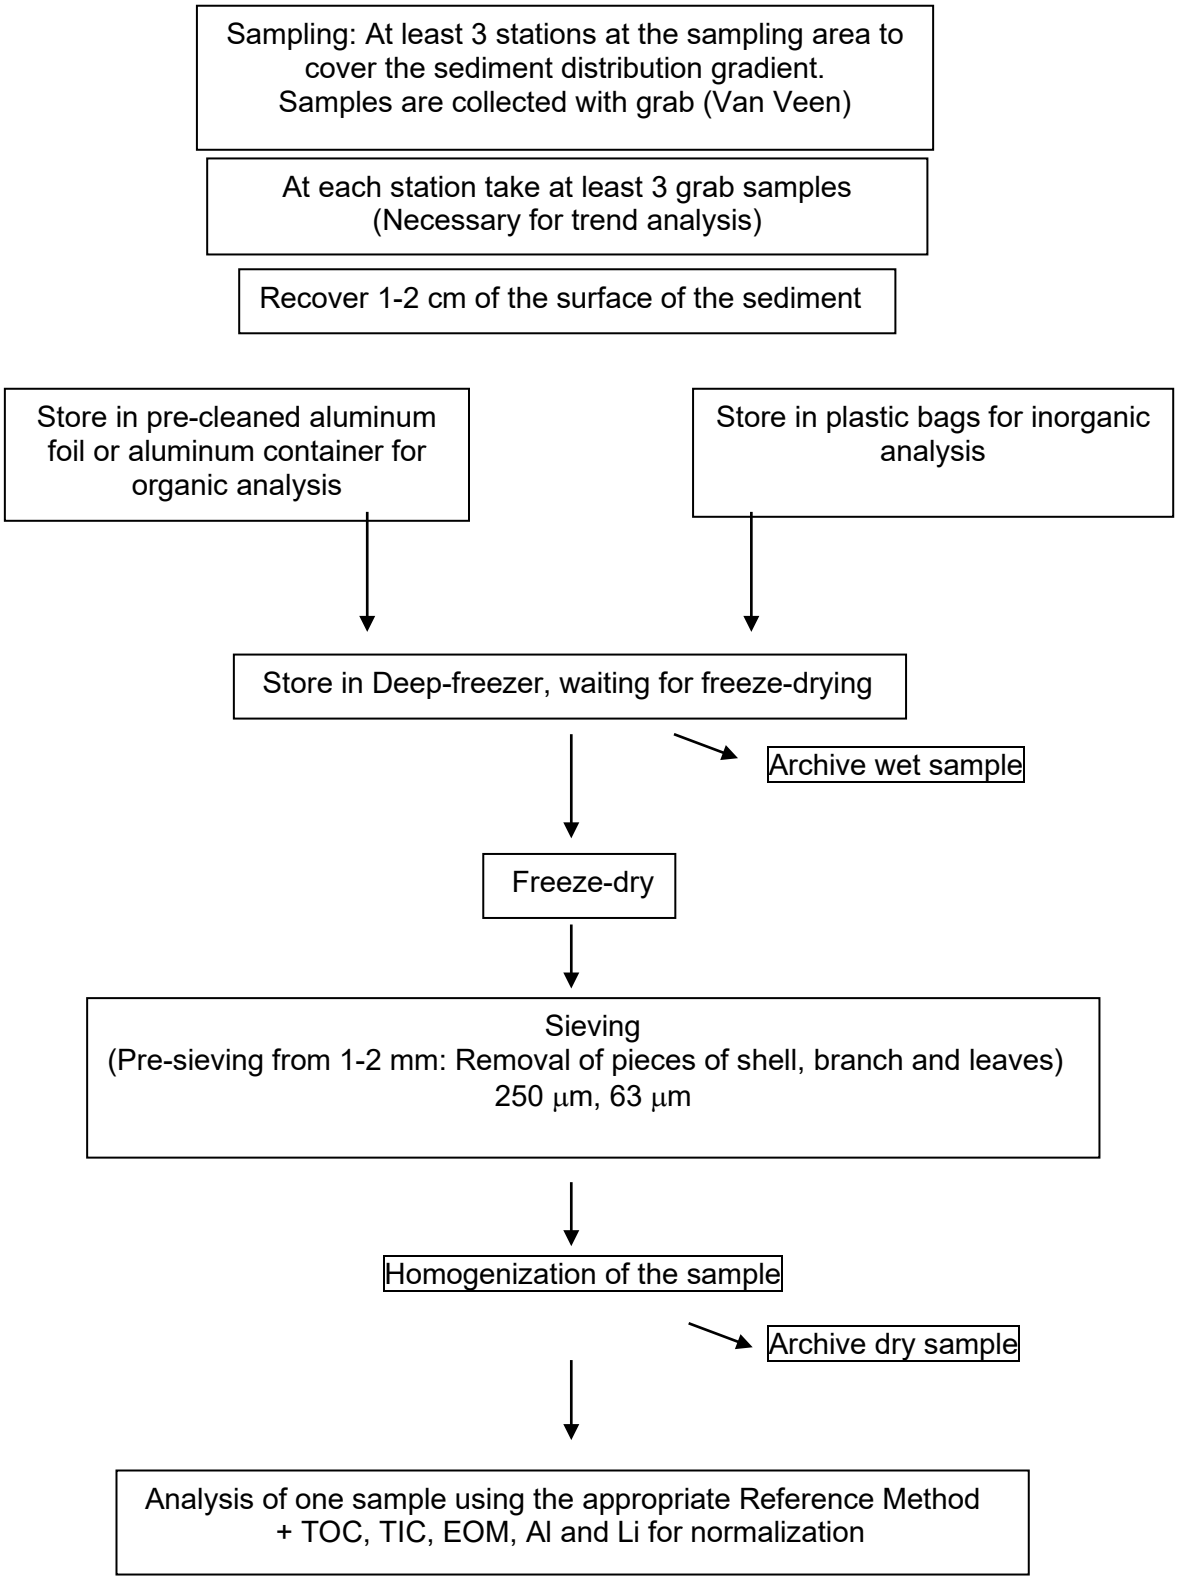
One procedure that could be useful in many cases is:

- From observations, calculate all basic parameters and variables.
- Observe the $^{210}Pb_{ex}$ profile, looking for deviations from the ideal exponential decay and formulating working hypothesis. If the core appears to be mixed, its use to reconstruct environmental conditions would be compromised and only MAR and SAR should be derived.
- Use the CF model to calculate the $^{210}Pb_{ex}$ flux to the surface sediment and compare it with other sediment cores and atmospheric fluxes. A deficit would imply sediment erosion and, therefore, its use to reconstruct environmental conditions would be compromised.
- Obtain the core age-model and section accumulation rates by using the CF model. Validate the CF age model.
- Obtain the MAR and SAR for each layer by using the CF model. Obtain the MAR and SAR for each section as the mean of 2 consecutive layers.
- Obtain mean accumulation rates (MAR and SAR) by using the CFCS model.
- If the $^{210}Pb_{ex}$ profile shows good linearity and the CF model cannot be validated, ages could be estimated form the MAR and massic depth by using the CFCS linear regression equation.

8. Conclusions

We can consider two different approaches to the sediment sampling for monitoring projects. They follow the schematics below depending on the budget and the manpower of the laboratories. One of the methods is a minimum requirement and the other would be the “state-of-the-art” methodology.

First approach (easiest and cheapest one):



Second approach (complete procedure):

Monitoring Guidelines/Protocols for Sample Preparation and Analysis of Sediment for IMAP Common Indicator 17: Heavy and Trace Elements and Organic Contaminants

1. Introduction

1. Determination of the concentrations of targeted heavy metals and organic contaminants in different marine matrices is a key component of the IMAP, since the analytical results will contribute to the assessment of the environmental status of the water body under consideration. Sediment is one of the proposed matrices for the analysis of heavy metals and organic contaminants since the establishment of the UNEP/MAP – MED POL Monitoring programme in 1981 (MED POL Phase II), because many heavy metals and persistent organic contaminants in seawater tend to become insoluble and precipitate with the particulate fraction on the seafloor. Therefore, since sediment is the ultimate sink of most heavy metals and persistent organic contaminants, which are introduced into the marine environment, their analysis will provide a clear view of the pollution state of the specific water body. Furthermore, in areas with undisturbed sediments, the yearly deposited sedimentary material integrates the pollution load during this specific time period, and the analysis of different sedimentary layers is providing a historical trend of pollution processes in the region.

2. Contaminants may enter the marine environment form land- and sea-based sources as well as through atmospheric deposition. Land-based sources are mainly affecting coastal sediments, where the higher metal and organic contaminants concentrations are usually found at the vicinity of pollution "hot spots" (coastal cities and industrial areas, river mouths draining highly populated and/or industrialized basins). Offshore sediments are mainly influenced by atmospheric deposition, which play globally a very important role, especially for some metals (such as Hg) and organic contaminants (such as PAHs).

3. Heavy metal sources are both natural and anthropogenic. Therefore, it is important to be able to differentiate between metal enrichments caused by natural causes (such as sediment's mineralogy and granulometry) and those originating from human activities (urban, industrial). To that end, normalization of the heavy metal data is often used, in view of detecting the human imprint on the heavy metal distribution in sediment. On the other hand, persistent organic contaminants sources are solely anthropogenic, therefore the total contaminant's load is of anthropogenic origin.

4. In line with IMAP requirements (UNEP/MAP, 2019a[221],UNEP/MAP, 2019b[222]), mandatory contaminants to be analysed in the marine sediment include: heavy metals (Cadmium (Cd), Lead (Pb) and total Mercury (THg)), organochlorinated compounds (PCBs, hexachlorobenzene, lindane and ΣDDTs) and Polycyclic Aromatic Hydrocarbons (US EPA 16 Reference PAHs compounds). Also, additional parameters to be analysed in sediment are: Aluminium (Al), Total Organic Carbon (TOC), grain size (<2 mm and <63 μm).

5. The UNEP/MAP Proposed assessment criteria (Background Assessment Criteria -BAC and Environmental Assessment Criteria - EAC) for targeted heavy metals and organic contaminants in sediments are presented in the Annex XIV.

6. The Protocols prepared in the framework of this Monitoring Guidelines/Protocols for Sample Preparation and Analysis of Sediment for IMAP Common Indicator 17, as provided here-below, describe appropriate methodologies for the analysis of marine sediments for the determination of heavy metals and organic contaminants, in order to ensure quality assured data. They are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories, which should be tested and modified in order to validate their final results.

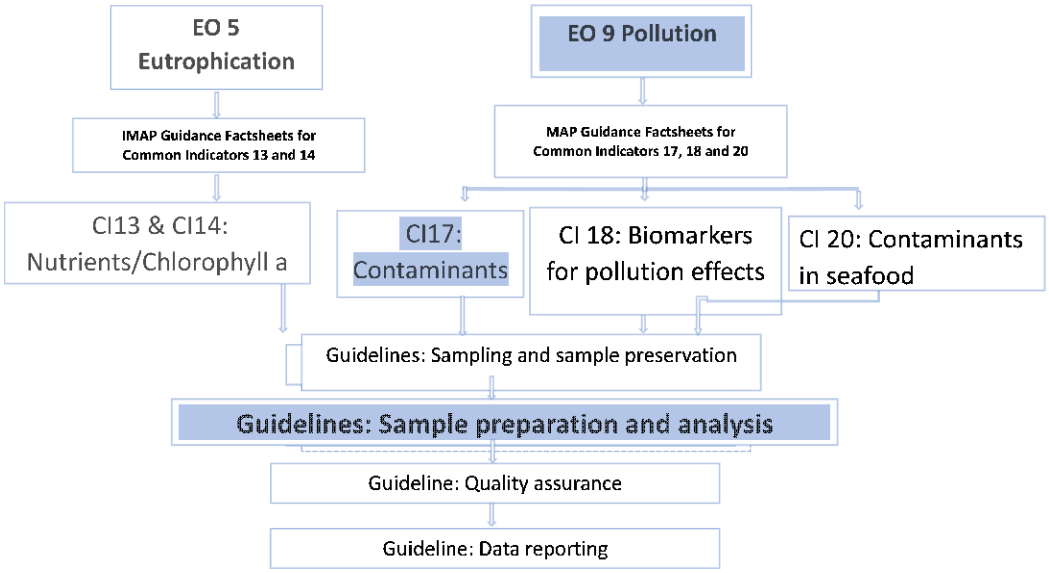
---

[221] UNEP/MAP (2019a). UNEP/MED WG.467/5. IMAP Guidance Factsheets: Update for Common Indicators 13, 14, 17, 18, 20 and 21: New proposal for candidate indicators 26 and 27;
[222] UNEP (2019b). UNEP/MED WG.463/6. Monitoring Protocols for IMAP Common Indicators related to pollution;

7. These Protocols aim at streamlining marine sediment sample preparation and analysis for heavy metals and organic contaminants in a view of assuring comparable quality assurance of the data, as well as comparability between sampling areas and different national monitoring programmes. They provide a step-by-step guidance on the methods to be applied in the Mediterranean area for sampling and sample preservation of sediments.

8. In order to avoid unnecessary repetitions, reference is also made to the protocols already published and publicly accessible, which can also be used by the Contracting Parties' competent laboratories participating in IMAP implementation. They build upon the UNEP/MAP - IAEA Recommended Methods for the analysis of heavy metals and organic contaminants, such as: IAEA (2011a) Recommended method on microwave digestion of marine samples for the determination of trace element content (Annex I); IAEA (2011b) Recommended method for the determination of selected trace element in samples of marine origin by flame atomic absorption spectrometry (Annex III); IAEA (2011c) Recommended method for the determination of selected trace element in samples of marine origin by atomic absorption spectrometry using graphite furnace (Annex IV); IAEA (2012a) Recommended method on the determination of Total Hg in marine samples by Thermal Decomposition Amalgamation and Atomic Absorption Spectrometry (Annex VI); IAEA (2012b) Recommended method for the determination of mercury in samples of marine origin by cold vapour atomic absorption spectroscopy (Annex VII); UNEP/IAEA (2011d) Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment: Reference Methods for Marine Pollution Studies No 71 (Annex VII); , which were prepared in the framework of the MED POL monitoring programme. They are also streamlined with similar Guidelines/Protocols for marine sediment sample preparation and analysis which were developed by other Regional Organisations, such as OSPAR (Annex II, VIII, X and XII) and HELCOM (Annexes XI and XIII), therefore any of these Guidelines are equally suitable to be applied in the context of IMAP, as well as and US EPA (Annex V). Given the suitability of any of these Guidelines in the context of IMAP, they could be further used by interested IMAP competent Mediterranean laboratories for developing their laboratory specific sampling and sample processing methodologies. The Contracting Parties' laboratories should accommodate and always test and modify each step of the procedures to validate their results.

9. The below flow diagram informs on the category of this Monitoring Guideline related to sample preparation and analysis of sediment for IMAP Common Indicator 17 within the structure of all Monitoring Guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.



Flow Diagram: Monitoring Guidelines for IM Ecological Objectives 5 and 9

2. Technical note for the analysis of heavy metals in sediment

10. Analysis of marine sediment samples for the determination of heavy metals[223] include: i) digestion of sediments and ii) analysis of the digested sample for heavy metals. Cd, Pb and THg are the mandatory metals to be determined in marine sediment samples (UNEP/MAP, 2019a). However, the Contracting Parties to the Barcelona Convention may decide to include in their national monitoring programmes the analysis of additional heavy metals according to their national priorities.

11. National laboratories may decide to use any validated analytical method they consider appropriate, which meets specific performance criteria (LOD, LOQ, precision, recovery and specificity). However, in order to assist analytical laboratories of the Contracting Parties, the IMAP Protocols in order to be used as guidelines for the analysis of heavy metals and trace elements in marine sediment samples. Analytical laboratories should accommodate, test and modify each step of the procedures presented in the Protocols in order to validate their final results. The list of methods and analytical equipment is not exhaustive, and laboratories are encouraged to use their own equipment/methods that consider adequate for the required analyses.

12. Regardless of the analytical method used, heavy metal analysis follow some procedures common to all analytical methodologies, such as the calibration of the analytical equipment and the cleaning and handling procedures to avoid the contamination of the samples from the laboratory's environment and the tools and containers used in the analysis.

a) Calibration

13. Calibration standards prepared from single standard stock solutions or multielement standards, by dilution of the stock solution using dilute acid, as required. All standard solutions have to be stored in polyethylene, borosilicate or quartz volumetric flasks. Standard solutions with lower concentrations, if prepared correctly and controlled in a QA system (checking of old versus new standards, and checking with standards from a different source), can be kept for a period no longer than one month

[223] In the Guideline text the term "heavy metals" is used to designate both heavy metals and trace elements

14. The calibration procedure has to meet some basic criteria in order to provide the best estimation of the true element concentration of the sample analysed (HELCOM, 2012a[224]):

i) the concentrations of standards for the preparation of the calibration curve should cover the range of anticipated concentrations;

ii) the required analytical precision should be known and achievable throughout the entire range of concentrations;

iii) the measured value at the lower end of the range has to be significantly different from the procedural analytical blank;

iv) the chemical and physical properties of the calibration standards must closely resemble those of the sample under investigation.

b) Avoiding contamination

15. To avoid metal contamination in the laboratory all glassware and plastic vessels used should be carefully cleaned. The general cleaning guidelines include:

i) Allow the vessels to soak overnight in a plastic container in a soap solution (solution 2% in tap water);

ii) Rinse thoroughly first with tap water then with ultrapure deionised water;

iii) Leave the vessels to stand in 10% (v/v) concentrated HNO_3 solution at room temperature for at least 6 days;

iv) Rinse thoroughly with Milli-Q water (at least 4 times);

v) Allow the vessels to dry under a laminar flow hood;

vi) Store the vessels in zip-lock plastic polyethylene bags to prevent the risk of contamination prior to use.

16. This procedure should be used for all plastic ware use in the laboratory as tips, cup for autosampler, plastic containers.

17. Under this Technical Note, the Guideline for Sample Preparation and Analysis provides the following IMAP Protocols:

- Protocol for sediment digestion using nitric acid and hydrofluoric acid (microwave assisted digestion in closed systems and digestion on hot plate);
- Protocol for the analysis of heavy metals with Flame Atomic Absorption Spectroscopy (F-AAS;
- Protocol for the analysis of heavy metals with Graphite Furnace Atomic Absorption Spectroscopy (GF-AAS);
- Protocol for the analysis of heavy metals with Inductive Coupled Plasma – Mass Spectroscopy (ICP-MS);
- Protocol for the analysis of Total Mercury with solid Hg analyser;
- Protocol for the analysis of Total Mercury in samples or marine origin by Cold Vapour Atomic Absorption Spectrometry;
- Protocol for the normalization of heavy metal concentrations using Al.

[224] HELCOM (2012a). Manual for marine monitoring in the COMBINE programme. Annex B-13 Appendix 3: Technical note on the determination of heavy metals and persistent organic compounds in marine sediment.

18. These Protocols are based on Analytical Methods developed by IAEA (Annex I: Recommended method on microwave digestion of marine samples for the determination of trace element content ; Annex III: Recommended method for the determination of selected trace element in samples of marine origin by flame atomic absorption spectrometry; Annex IV: Recommended method for the determination of selected trace element in samples of marine origin by atomic absorption spectrometry using graphite furnace; Annex VI: Recommended method on the determination of Total Hg in samples or marine origin by Cold Vapour Atomic Absorption Spectrometry and Annex VII: Recommended method for the determination of mercury in samples of marine origin by cold vapour atomic absorption spectroscopy), OSPAR (Annex II: CEMP Guidelines for Monitoring Contaminants in Sediments. Technical Annex 6: Determination of metals in sediments – analytical methods, Annex VIII: CEMP Guidelines for Monitoring Contaminants in Sediments. Technical Annex 5: Normalisation of contaminant concentrations in sediments), and US EPA (Annex V: US-EPA Method 6020B. ICP-MS method for the determination of elements in water samples and in waste extracts or digests).

2.1 Protocol for sediment digestion using nitric acid and hydrofluoric acid

19. Sediment samples have to be digested (wet ashing) prior to analysis. The rate of digestion and the efficiency of acid decomposition increase substantially with elevated temperatures and pressure, therefore microwave digestion in closed vessels is the preferred method. However, in case no such equipment is available, sample digestion in open vessels over a hot plate is an alternative method.

20. IMAP requires the complete disintegration of the silicate matter of sediments using Hydrofluoric acid (HF) in order to measure the total metal load in sediments, including Al, which is needed for normalization purposes. Furthermore, Certified Reference Materials (CRMs) of sediments provide certified values for total metal concentrations, therefore their use to strengthen data quality assurance requires the measurement of the total metal content in sediment samples

a) Microwave acid digestion in closed systems for heavy metals for AAS, GFAAS and ICP-MS analysis

21. Sediment digestion can be performed in Teflon, or equal quality vessels, which are metal free and resistant to strong acids including HF (Loring and Rantala, 1991[225]). Dried sediment samples (0.1 to 0.5 g) are weighted in the microwave vessel and placed in a laminar hood compatible with acid fume. Approximately 5 ml of analytical grade nitric acid and 2 ml of analytical grade hydrofluoric acid are added and each vessel and let to react for at least 1hour (or more if possible). After the room temperature pre-digestion, 2ml of hydrogen peroxide (analytical grade) are added carefully, the vessels are closed and placed in the microwave apparatus and digestion steps are performed, following the IAEA's Recommended method on microwave digestion of marine samples for the determination of trace element content (Annex I. IAEA 2011a[226]). Oxygen peroxide and organic matter can promote an explosive reaction, so this acid must be treated with great caution when added to the sediment. Also because closed vessels retain the HF, boric acid is added after the HF digestion to complex the remaining HF and make the resulting solution less hazardous, as well as preventing aluminium fluoride precipitation. After digestion the vessels are removed from the microwave apparatus and placed in a ventilated fume hood to cool. When the pressure is adequate, the vessels are opened, and their content is transferred into a 50 ml polypropylene graduated tubes. At least one Certified Reference Material should be used and prepared in duplicate for each digestion batch. These digestions

[225] Loring, DH and Rantala RTT (1991). Manual for the geochemical analyses of marine sediments and suspended particulate matter. Earth-Science Review, 32: 235:283. Elsevier Science Publishers B.V

[226] IAEA (2011a). Recommended method on microwave digestion of marine samples for the determination of trace element content (IAEA/Marine Environmental Studies Laboratory in co-operation with UNEP/MAP MED POL)

are prepared in a similar manner as the samples. A reference material of similar composition and concentration range should be used.

22. Microwave assisted acid digestion of sediments are also proposed by OSPAR (2018a[227]) (Annex II), HELCOM (2012a) and US EPA (1996[228]) (Method 3052).

b) Acid digestion over a hot plate

23. In case no microwave digestion system is available, it is possible to perform digestion over a programmable heating plate placed inside a metal free and acid resistant fume hood, allowing HF and other acids treatment. Sediment samples are treated in closed Teflon vessels with hydrofluoric acid (HF) in combination with aqua regia in order to decompose the samples. The use of HF is essential because it is the only acid that completely dissolves the silicate lattices and releases all the metals. However, it should be noted that digestion in open systems may lead to loss of Hg (Delft and Vos, 1988[229]), while great care should be made to avoid loss of material because of violent boiling reactions. Therefore, digestion over a hot plate is not a recommended method and should be avoided if possible.

24. Several acid mixtures (together with HF) have been used for sediment digestion over a hot plate, such as aqua regia, nitric acid or perchloric acid (Loring and Rantala, 1991; Cook et al, 1997[230]). In case perchloric acid is used solutions are left to stand for a period of 1 hour – overnight to avoid problems with violent reactions, which may be prompted by the presence of organic matter in the sediment. Then the vessels are closed and placed on a hot plate at 120 °C or in boiling water for 1-2hdepending on the method followed. Then the samples are allowed to cool to room temperature, the tubes are opened and boric acid is added to complex the remaining HF (OSPAR 2018a).

2.2 Protocol for the analysis of heavy metals with Flame AAS

25. In most marine sediments Al, Cu, Cr, Fe, Ni, Zn, as well as other metals, can be determined by Flame Atomic Absorption Spectroscopy, which has adequate sensitivity for these determinations.

26. In Atomic Absorption Spectrometry the sample solution is aspirated into a flame and atomized. A light beam is directed through the flame, into a monochromator, and onto a detector that measures the amount of light absorbed by the element in the flame. Each metal has its own characteristic wavelength so a source hollow cathode lamp composed of that element is used. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

27. Metal standard solutions for the calibration curve are prepared from stock standard solution (1000 mg l^{-1} or an intermediate stock standard). Depending on the element, it may be necessary to make an intermediate stock standard solution. This intermediate stock is prepared as described in the Technical Note in a 2% HNO_3 matrix. The calibration curve is determined according to the expected concentrations of the samples, and the linearity of the AAS response for the element is considered (absorbance versus concentration curve given in the analytical methods book). If ionization or

[229] Delft W. van; Vos. G. (1988) Comparison of digestion procedures for the determination of mercury in soils by cold-vapor atomic absorption Spectrometry; Analytica Chimica Acta, 209, 147-156.
[230] Cook JM, Robinson JJ, Chenery SR and Miles DL (1997). "Determining cadmium in marine sediments by inductively coupled plasma mass spectrometry: attacking the problems or the problems with the attack?" Analyst, 122, 1207-1210

interferences are likely, the right option according to the analytical method book has to be chosen, e.g. use of correction for non-atomic absorption by using deuterium lamp background corrector; use of oxidizing air-acetylene flame; use of nitrous oxide-acetylene flame; addition of a releasing agent or ionization suppressant.

28. A detailed analytical protocol for the analysis of heavy metals in sediments prepared by IAEA (2011b) is presented in the Annex III.

2.3 Protocol for the analysis of heavy metals with GF-AAS

29. In marine sediments Cd, Pb, Cu as well as other metals, can be determined by Graphite Furnace Atomic Absorption Spectroscopy (GF-AAS), which has adequate sensitivity for these determinations. For GF-AAS analysis, after the digestion of the sediment sample, an aliquot of sample solution (10-50 µl) is introduced into a graphite tube of the GF-AAS and atomized by rapid heating at high temperature. A light beam is directed through the graphite tube, into a monochromator, and onto a detector that measures the amount of light absorbed by the atomized element in the tube. Each metal has its own characteristic wavelength, so a source hollow cathode lamp composed of that element is used. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

30. The reagents used include: argon, standard solution of the element of interest 1000 mg l^{-1} , deionized water. All reagents should be of analytical grade.

31. A detailed analytical protocol for the analysis of heavy metals in sediments by GF AAS prepared by IAEA (2011c[231]) is presented in the Annex IV.

32. The AAS software generally gives typical electrothermal programs for each element for 10 µl of sample in diluted HNO_3 (0.1%) and indications concerning maximum ashing and atomization temperatures. More specific information may also be found in the literature, such as recommendations regarding matrix modifiers and the use of partition tubes or tubes with platform. When a program is optimized for the determination of an element in a specific matrix, all information should be reported in the logbook of methods of the laboratory.

33. For some elements and some matrices, the results obtained are still not satisfactory (e.g. maximum ashing temperature is not sufficient to eliminate the background), this procedure should be redone with the addition of a matrix modifier. Different matrix modifiers could be tried before finding the best solution.

2.4 Protocol for the analysis of heavy metals with ICP-MS

34. Inductive Coupled Plasma – Mass Spectroscopy (ICP-MS) is currently state-of-the-art instrumentation for metal analysis, with the possibility to determine at sub-µg L^{-1} concentrations of a large number of elements in water and acid digested sediment samples.

35. Typical limits of detection for the determination of trace metals with ICP-MS (in mg kg^{-1} d.w.) based on typical sample intakes (0.5 –1 g), are as follows (OSPAR, 2018):

Al	Li	As	Cd	Cr	Cu	Hg	Ni	Pb	Zn
40	0.1	1	0.01	0.2	0.1	0.05	0.2	0.2	2

[231] IAEA (2011c). Recommended method for the determination of selected trace element in samples of marine origin by atomic absorption spectrometry using graphite furnace

36. Inductively coupled plasma attached to a mass spectrometer (ICP-MS) allows a rapid analysis of a wide range of heavy metals. Most routine instruments utilize a quadrupole mass spectrometer, so mass resolution is not high enough to avoid overlap of double charged elements or multi-element ions (mainly hydrides, oxides and hydroxides) formed in the plasma. The main concern is for the Ar interferences as the plasma is usually an argon plasma. Some elements are prone to memory effects (particularly Hg) and needs extra precautions to avoid carry over effects. Modern ICP-MS instruments software includes all the tuning and correction formulas needed and described above to perform the analysis (HELCOM 2012a).

37. A multi-elemental determination of heavy metals by ICP-MS in water and solid samples after acid digestion, is described in the US EPA Method 6020B (2014 revision). Metal species originating in a liquid are nebulized and the resulting aerosol is transported by argon gas into the plasma torch. The ions produced by high temperatures are entrained in the plasma gas and introduced, by means of an interface, into a mass spectrometer. The ions produced in the plasma are sorted according to their mass-to-charge ratios and quantified with a channel electron multiplier. Interferences must be assessed and valid corrections applied. Interference correction must include compensation for background ions contributed by the plasma gas, reagents, and constituents of the sample matrix. The US EPA Method 6020B is presented in Annex V (US EPA 2014[232]).

2.5 Protocol for the analysis of Total Mercury with solid Hg analyser

38. Total mercury in the sediment can be analysed by solid Hg analyser, which has adequate sensitivity for this determination. The sample is dried and then chemically decomposed under oxygen in the decomposition furnace. The decomposition products are carried out to the catalytic section of the furnace, where oxidation is completed (halogens and nitrogen/sulfur oxides are trapped). The mercury present in the remaining decomposition products is selectively trapped on an amalgamator. After flushing the system with oxygen, the mercury vapour is released by rapid heating of the amalgamator and carried through the absorbance cell in the light path of a single wavelength atomic absorption spectrophotometer. The absorbance is measured at 253.7 nm as a function of mercury quantity (ng). The typical working range is 0.1–500 ng. The mercury vapour is carried through a long (first) and a short path length absorbance cell. The same quantity of mercury is measured twice with different sensitivity resulting in a dynamic range that spans four orders of magnitude. The typical detection limit is 0.01 ng of mercury.

39. Calibration standards should be prepared from single standard stock solutions or multielement standards by dilution of the stock solution using dilute acid, as required. All standard solutions have to be stored in Teflon, borosilicate or quartz volumetric flasks in 0.5-1 % HNO_3 and 0.1% (v/v) potassium dichromate. An alternative calibration curve can be performed using a solid certified reference material.

40. A detailed method describing the protocol for the determination of total mercury (inorganic and organic) in sediment prepared by IAEA (2012a[233]) ANNEX V): Recommended method on the determination of Total Mercury in marine samples by thermal decomposition, amalgamation and Atomic Absorption Spectrophotometry. With this method, Total Hg is determined without any chemical pre-treatment of the sample, minimising possible contamination and/or additional errors due

[232] USEPA (2014 revision) Method 6020B, ICP-MS. Environmental protection Agency, Washington, DC.
[233] IAEA (2012a) Recommended method on the determination of Total Hg in marine samples by Thermal Decomposition Amalgamation and Atomic Absorption Spectrometry

to sample handling. (Annex VI). The method is based on the US EPA 7473 method (US EPA, 2007a[234]).

2.6 Protocol for the analysis of Total Hg in sediments by CV-AAS

41. In the Cold Vapour Atomic Absorption Spectrometry (CV-AAS) method, the inorganic mercury is reduced to its elemental form with stannous chloride. The cold mercury vapour is then passed through the quartz absorption cell of an AAS instrument where its concentration is measured. The light beam of Hg hallow cathode lamp is directed through the quartz cell, into a monochromator and onto a detector that measures the amount of light absorbed by the atomized vapour in the cell. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

42. The method is simple, rapid and applicable to a large number of environmental samples with a typical working range 0.25–100 ng mL^{-1} for direct injection of cold vapour, using "batch" system. CV-AAS analysis can be performed manually using batch CV-AAS or automatically using flow injection (FIAS) techniques. FIAS is a very efficient approach for introducing and processing liquid samples in atomic absorption spectrometry, reduces sample and reagent consumption, and has a higher tolerance of interferences, lower determination limits and improved precision compared with conventional cold vapour techniques (HELCOM, 2012b[235]).

43. A detailed Recommended Method prepared by IAEA (2012b[236]) describing the protocol for the determination of total mercury in sediment using CV-AAS is presented in Annex VII. Methods for the determination of Total Hg in marine biota using CV-AAS are also prepared by HELCOM (2012b) and US EPA (2007b[237]).

2.7 Protocol for the normalization of heavy metal concentrations using Al

44. Normalization is defined here as a procedure to adjust heavy metal concentrations for the influence of the natural variability in sediment composition, grain size and mineralogy. In non-polluted sediments heavy metal concentrations usually increase with decreasing grain size of the sediment and therefore any differences in metal concentrations caused by pollution sources will be obscured by grain size differences. Normalization is therefore applied to differentiate between natural variability and anthropogenic input of contaminants.

45. A normalization approach is to consider that in sandy sediments heavy metals concentrations are considered as negligible, therefore metal concentration determined in the <2 mm fraction could be subsequently normalized to a sample consisting of 100% of the <63 μm fraction. However, this approach cannot always successfully compensate for metal variability, because natural trace metal concentrations and their variability in sediments are determined not only by grain size distribution, but also by the composition of minerals and secondary compounds.

46. To overcome this drawback, a geochemical normalization approach is often used. This technique consists in establishing the mathematical relationships between metal concentrations and the concentrations of a conservative element, which represents a certain mineral fraction of the sediment. Elements of natural origin which are structurally combined to one or more of the major fine-grained trace metal carriers are considered conservative and have been used for normalization purposes. Aluminium (Al) has been the most widely used element for normalization, because it is a major constituent of fine-grained aluminosilicates with which the bulk of trace metals are associated. However, this assumption may not be valid in all cases, since there are components in sediment which may also serve as hosts for contaminants with an even higher sorptive capacity but contain neither Si nor Al, such as organic matter, Fe/Mn oxides, or sulfide minerals (Kestern and Smedes, 2002[238]). Furthermore, when the sediment is derived from glacial erosion of igneous rocks, with significant amounts of aluminium present in feldspar minerals contributing to the coarse fraction, it is preferable to use lithium as a conservative element for normalization (Loring 1991[239]).

47. The main assumption for the application of a geochemical normalization to a conservative element is the existence of a linear relationship between the normalizer and other metals. Such a relationship suggests that, in the natural sediments of an area, the concentration of the metal will change proportionally to the concentration of the normalizer. Also, a linear relationship must exist between the normalizer's concentration and the percentage of fine-grained (silt and clay) content of the samples. Such a relationship would allow the use of the normalizer concentrations as a proxy for granulometric variability of the sediments, in order to distinguish the pollution-related metal enrichment from the natural enrichment caused by grain size variability (Loring and Rantala 1991).

Normalization procedure

48. Heavy metals (Me) concentrations are divided by the concentration of the normalizer (or co-factor) in each sample. The Me/Al ratio in the references stations represent the natural relationship between the two metals in the sediments of the area, while higher Me/Al ratios indicate metal enrichment, which cannot be explained by the natural textural variability, and should be attributed to anthropogenic inputs. A more detailed approach will calculate the regression line (and the slope) between the metal and the normalizer (Al) concentrations in the sediments of an area. In order to ensure that the changes in the normalizer's concentration reflect the differences in finer material content, it is necessary to also establish a statistically significant regression between the normalizer (Al) and the finer fraction of the sediments (i.e. clay < 2 μm or even silt+clay < 63 μm), in order to check that the normalizer is suitable to be used as a proxy of the finer sediment (Loring 1991).

49. Kestern and Smedes (2002) propose to analyse also the sand fraction (>63 μm) in order to calculate the Al (or Li) concentrations in the coarse sediments. They propose a model as presented in Figure 1. "C_X and N_X represent the co-factor and the contaminant contents possibly present in the coarse material (*e.g.*, Al in feldspar) and can be estimated from samples without fine material. The regression line between the contaminant and co-factor will originate from that point. Regressions of co-genetic data sets but with a different contamination levels will have this point in common but tend to develop different slopes from this "turning point". In principle, therefore, only one additional sample is required to estimate the slope for a co-genetic sample set if this turning point is known. The slope for this sample with a contaminant content C_S and a co-factor content N_S can be expressed as follows":

[238] Kestern, M. and Smedes, F. (2002). Normalization procedures for sediment contaminants in spatial and temporal trend monitoring. J. Environ. Monit. 4, 109-115.
[239] Loring, DH (1991). Normalization of heavy metal data from estuarine and coastal sediments. ICES J. Mar. Sci. 48, 101-115

$$P_L = \frac{dC}{dN} = \frac{C_S - C_X}{N_S - N_X}$$

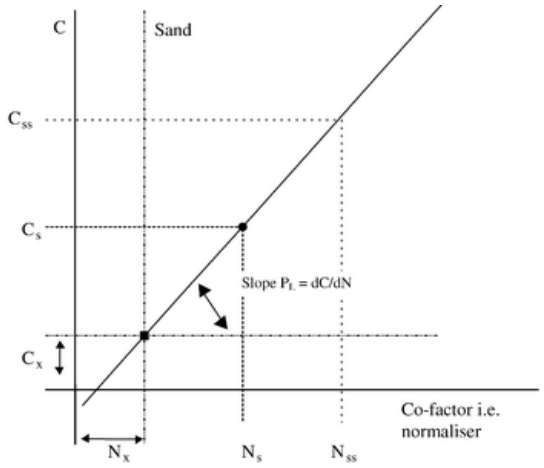

Figure 1. Contaminant content C_S and a co-factor content N_S (Kestern and Smedes, 2002, in OSPAR, 2018b[240])

50. The slope of the regression represents the natural relationship between the metal and the co-factor (normalizer). Therefore, "regression lines drawn for samples from different areas may thus be used to compare their degree of contamination. The steeper the gradient, the more contaminated an area is considered to be Positive residuals that plot above this line indicate that the concentrations are greater than would be predicted from the contaminant/co-factor relationship, and may represent hot-spot samples" (Kestern and Smedes, 2002, in OSPAR 2018b).

51. Kestern and Smedes (2002) also underline that "the precision of the result strongly depends on the natural (or analytical) variability of N_X. For coarse-grained samples, a significant standard deviation in both the C_X coefficient and the slope may arise from propagation of the errors of the analytical variation due to the overall low concentrations. The C_X coefficient of the regression may differ significantly from site to site, in particular, when using coarser grain size fractions. For some areas, Al contents in the coarse fractions are found at the same level as in the fines, and therefore the intercept N_X becomes very high. This implies that the denominator is the result of subtracting two relatively large numbers, N_S and N_X. Consequently, due to their individual uncertainties, the result has an extreme error." (OSPAR, 2018b). In MED POL IMAP, it has been decided to analyse the < 2 mm fraction of the sediment, therefore it is possible that *Ns* and *Nx* will be relatively high.

52. A similar approach to calculate the regression between metal and the normalizer is presented by Loring and Rantala (1992). Using data form the non-polluted (or reference) stations scatter plots of the regression lines between the metals and the normalizer (Al or Li) with 95% confidence bands are drawn. The regression line represents the natural variability of the metal concentrations in relation to the normalizer (Al or Li) content and the stations located within the confidence bands can be considered as non-polluted. On the other hand, stations located above the upper limit of the 95% confidence band may be considered as polluted.

53. A detailed discussion on normalization procedures can be found in OSPAR's Technical Annex 5: Normalisation of contaminant concentrations in sediments (OSPAR, 2018b) (Annex VIII).

[240] OSPAR (2018b). CEMP Guidelines for Monitoring Contaminants in Sediments. Technical Annex 5: Normalisation of contaminant concentrations in sediments.

54. The purpose of normalization is to reduce the variability between samples arising from differences in bulk sediment properties in order to draw conclusions on the level of metal contamination in a specific area, and/or to compare pollution levels between different areas. However, in some areas that the correlations between contaminant and cofactor concentrations may be weak or even absent. Therefore, normalization should be used taking into consideration its limitations and having a good knowledge of the characteristics of the sediments in the area under investigation.

3. Technical note for the analysis of organic contaminants in marine sediments

55. The mandatory organic contaminants to be analysed in sediments in the framework of IMAP are: Organochlorinated compounds (PCBs [28, 31, 52, 101, 105, 118, 138, 153, 156, 180], Hexachlorobenzene, Lindane and ΣDDTs) and polycyclic aromatic hydrocarbons (US EPA 16 individual PAHs congeners – Acenaphene, Acenaphthylene, Anthracene, Benz(a)anthracene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Benzo(a)pyrene, Benzo(ghi)perylene, Chrysene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Naphthalene, Phenanthrene, Pyrene) (UNEP/MAP, 2019a; UNEP/MAP 2019b). However, Parties may decide to include in their national monitoring programmes the analysis of additional heavy organic compounds according to their national priorities.

56. Analysis of sediment samples for the determination of organic contaminants include: i) extraction; ii) concentration; iii) clean-up; iv) fractionation; and v) quantification of contaminants.

57. National laboratories may decide to use any validated analytical method they consider appropriate, which meets specific performance criteria (LOD, LOQ, precision, recovery and specificity). However, in order to assist analytical laboratories of Mediterranean Parties, a list of Protocols has been drafted to be used as guidelines for the analysis of organic compounds in marine sediment samples. Analytical laboratories should accommodate, test and modify each step of the procedures presented in the Protocols in order to validate their final results. The list of methods and analytical equipment is not exhaustive, and laboratories are encouraged to use their own equipment/methods that consider adequate for the required analyses.

58. The laboratory area used for organic trace analysis must be a dedicated facility, isolated from other projects that could be sources of contamination. It must be properly constructed with fume hoods and benches with electric sockets that are safe for use with flammable solvents. The laboratory must have extractors and rotary evaporators cooling water to run the stills. In tropical regions and in dry climates, a refrigerated re-circulating system should be used to reduce temperatures to the required levels and/or to conserve water. Stainless steel or ceramic tiles make good non-contaminating surfaces. If necessary, benches can be coated with a hard epoxy resin and walls can be painted with epoxy paint. A sheet of aluminium foil on the workbench provides a surface which can be cleaned with solvent. A vented storage facility for solvents is essential. Benches must be fitted with frames to hold stills, extractors, etc. The emergency cut-off switch should be accessible from both inside and outside the laboratory. Firefighting equipment should be mounted in obvious places and laboratory personnel trained in their use.

59. Calibration of equipment for the analysis of organic contaminants follows the same procedures as in the analysis of heavy metals (Technical Note 2). All reagents, including the distilled water should be of analytical quality. Commercially available solvents like acetone, acetonitrile, dichloromethane, hexane and pentane are invariably contaminated with ECD-active substances and their concentrations vary from batch to batch and with supplier. Powdered or crystalline reagents, such as anhydrous sodium sulphate (Na_2SO_4), potassium hydroxide (KOH), glass wool, must be extracted with hexane in a Soxhlet apparatus. Adsorbents, such as silica gel, alumina and Florisil have also to be solvent extracted. All glassware should be vigorously scrubbed with brushes in hot water and detergent and rinse five times with tap water and twice with distilled water. Then, glassware should be rinsed with

acetone or methanol followed by hexane or petroleum ether and baked overnight in an oven at 300 °C. All glassware should be stored in dust free cabinets and tightly sealed with pre-cleaned aluminium foil when not in use. Ideally glassware should be cleaned just before use. More information on cleaning reagents and glassware is provided in UNEP/IAEA (2011[241]) (Annex IX.).

60. In the framework of this Technical note, this Guideline provides the following IMAP Protocols for the analysis of organic compounds in marine sediment samples:

- Protocol for the analysis of organochlorine pesticides and PCBs in sediment using Gas Chromatography-Electron Capture Detector (GC-ECD);
- Protocol for the analysis of organochlorine pesticides and PCBs in sediment using Gas Chromatography – Mass Spectrometry (GC-MS);
- Protocol for the analysis of PAHs in sediment using High Performance Liquid Chromatography - Fluorescence (HPLC-UVF);
- Protocol for the analysis of PAHs in sediment using GC-MS;
- Protocol for the normalization or organic contaminants concentrations in sediment using Total Organic Carbon (TOC).

61. These protocols are based on Analytical Methods developed by UNEP/IAEA (Annex IX: Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment. Reference Methods for Marine Pollution Studies No 71; Annex XII:), HELCOM (Annex XI: Manual for marine monitoring COMBINE programme, Annex B-12, Appendix 2. Technical note on the determination of chlorinated biphenyls and organochlorine pesticides in marine sediment; Annex XIII: Manual for marine monitoring in the COMBINE programme, Annex B-12, Appendix 1. Technical Note on the determination of Polycyclic Aromatic Hydrocarbons in sediment) and ICES/OSPAR (Annex X: CEMP Guidelines for monitoring contaminants in sediments, Annex 2 Analysis of PCBs in sediments; Annex XV: CEMP Guidelines for monitoring contaminants in sediments, Annex 3: Determination of parent and alkylated PAHs in sediments).

3.1 Protocol for the analysis of organochlorine pesticides and PCBs in marine sediments using GC-ECD

The analysis of PCBs and organochlorine pesticides (OCPs) in sediment samples involves the extraction from the matrix with organic solvents, followed by clean-up and gas chromatographic separation with electron capture (GC-ECD) or mass spectrometric (GC-MS) detection. The samples can be extracted dry or wet. The extracts are then concentrated in a rotary evaporator to about 15 ml, and cleaned for the removal of lipids (whenever present at a significant amount) and the removal of elementary sulphur and sulphur compounds. Both these compound classes can interfere with the gas-chromatographic separation. An adsorption chromatography step (using Florisil columns) could be used to remove interfering lipids and to fractionate the extract into classes of compounds.

62. To minimize systematic errors due to insufficiently optimized gas chromatographic conditions, determinant losses (evaporation, unsatisfactory extraction yield), and/or contamination from laboratory ware, reagents and the laboratory environment, it is essential that the sources of systematic errors are identified and eliminated as far as possible (HELCOM, 2012c[242]). All reagents, including the distilled water should be of analytical quality. Commercially available solvents like acetone, acetonitrile, dichloromethane, hexane and pentane are invariably contaminated with ECD-active substances; their

[241] UNEP/IAEA (2011). Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment. Reference Methods for Marine Pollution Studies No 71.
[242] HELCOM (2012c). Manual for marine monitoring in the COMBINE programme. Annex B-13 Technical note on the determination of heavy metals and persistent organic compounds in marine sediments. Appendix 2. Technical note on the determination of chlorinated biphenyls in marine sediment

concentrations vary from batch to batch and with supplier. Reagent quality should be checked by injection of 2 µl of a 100 ml batch of solvent, after concentration to 50 µl in a rotary evaporator. No peak in the GC-ECD chromatogram (90 – 250 °C) should be larger than that for 1pg of lindane. Otherwise, the solvent must be distilled.

63. Quantitative analysis with Electron Capture Detector (ECD) is performed by comparing the detector signal produced by the sample with that of defined standards. Due to incomplete separation, several co-eluting compounds can be present under a single detector signal, therefore, the shape and size of the signal have to be critically examined. The relative retention time and the signal size should be confirmed on columns with different polarity of their stationary phases, or by the use of multi-dimensional GC techniques. The GC should be calibrated before each batch of measurements. Since the ECD has a non-linear response curve, a multilevel calibration is strongly advised. For the purpose of determining recovery rates, an appropriate internal standard should be added to each sample at the beginning of the analytical procedure. The ideal internal standard is a PCB which is not present in the sample and which does not interfere with other PCBs. All 2,4,6-substituted PCB congeners are, in principle, suitable. Alternatively, 1,2,3,4-tetrachloronaphthalene or the homologues of dichloroalkylbenzylether can be used (HELCOM, 2012c).

64. For analysis, the samples are prepared for solvent extraction. To achieve a satisfactory recovery of the chlorinated hydrocarbons, samples are dried by either desiccation with anhydrous sodium sulphate or by freeze-drying. Lipids are then Soxhlet extracted from sediments using hexane and dichloromethane. Following initial clean-up treatments (removal of sulphur from sediment extracts), extracts are fractionated using column chromatography with an Electron Capture Detector (ECD). It is suggested, when using GC-ECD (and to a certain extent GC-MS), two columns with stationary phases of different polarity should be used, as column-specific co-elution of the target CBs with other CBs or organochlorine compounds occurs.

65. A protocol for the determination of organochlorine pesticides and polychlorinated biphenyls in sediment samples using CG-ECD prepared by UNEP/IAEA (2011) is presented in Annex IX. Similar analytical protocols using GC-ECD are also proposed by OSPAR (2018c[243]) (Annex X) and by HELCOM (2012c) (Annex XI.).

3.2 Protocol for the analysis of organochlorine pesticides and PCBs in sediments using GC-MS

66. The analysis of PCBs and organochlorine pesticides (OCPs) in sediment samples involves a similar extraction from the matrix with polar and non-polar organic solvents, followed by clean-up and gas chromatographic separation with mass spectrometric (GC-MS) detection.

67. Quantitative analysis is performed by comparing the detector signal produced by the sample with that of defined standards, using a mass spectrometer (MS). Often, due to incomplete separation, several co-eluting compounds can be present under a single detector signal. Therefore, the shape and size of the signal have to be critically examined. With a MS detector, either the molecular mass or characteristic mass fragments should be recorded for that purpose. The GC should be calibrated before each batch of measurements. Since the MS has a non-linear response curve, a multilevel calibration is advised. For the purpose of determining recovery rates, an appropriate internal standard should be added to each sample at the beginning of the analytical procedure. The ideal internal standard is a PCB which is not present in the sample and which does not interfere with other PCBs. All 2,4,6-substituted

[243] OSPAR (2018c) CEMP Guidelines for Monitoring Contaminants in Sediments. Technical Annex 2: technical annex on the analysis of PCBs in sediments.

PCB congeners are, in principle, suitable. Alternatively, 1,2,3,4-tetrachloronaphthalene or the homologues of dichloroalkylbenzylether can be used. For GC/MS, 13C-labelled PCBs should preferably be used as internal standards (HELCOM, 2012c).

68. A method for extraction, concentration, cleanup and fractionation for the determination of organochlorine pesticides and polychlorinated biphenyls in sediment samples is prepared by UNEP/IAEA (2011) (Annex IX.), including the list of reagents, the solvents, standards and examples for the preparation of the stock, intermediate and working solutions. All reagents, including the distilled water should be of analytical quality. Also, the analysis of PCBs and organochlorinated pesticides can be done by GC-ECD followed by confirmation using GC-MS.

69. Guidelines for the determination of organochlorine pesticides and polychlorinated biphenyls in sediment samples using CG-MS are also proposed by OSPAR (2018c) (Annex X) and by HELCOM (2012c) (Annex XI.).

3.3 Protocol for the analysis of PAHs in sediments using HPLC

70. PAHs in the marine environment may derive from combustion processes and from oil and oil products releases. Combustion PAHs are predominantly parent (unsubstituted) compounds, whereas oil and its products contain a much wider range of alkylated compounds in addition to the parent PAHs. This has implications for the analytical determination, as both HPLC-based and GC-based techniques are adequate for the determination of a limited range of parent PAHs in samples influenced by combustion processes, whereas in areas of significant oil contamination and following oil spills only GC-MS has sufficient selectivity to determine the full range of PAHs present.

71. For the analysis of sediments for PAHs, samples are defrosted and prepared for solvent extraction, which can be performed on wet or dried sediment. Wet sediment are Soxhlet extracted in two steps: first, using a polar solvent, such as acetone, to extract the water from the sediment, then the extraction continued with a less polar solvent or solvent mixture (e.g., acetone/hexane). Dry sediments can be Soxhlet extracted using medium-polar solvents such as dichloromethane or toluene, or mixtures of polar and non-polar solvents (OSPAR 2018d[244] Annex XII, HELCOM 2012d[245] Annex XIII).

72. Following extraction, the extract is concentrated and any polar solvents used in the extraction step are removed using a rotary evaporator to a volume of about 15 ml (the temperature of the water bath does not exceed 30 °C). The extract is dried with anhydrous sodium sulfate and transferred in a graduated tube and concentrated down to 4 to 5 ml using a flow of clean nitrogen.Then a clean-up is undertaken with purposes to remove of lipids, whenever present in significant amount; remove elementary sulphur and sulphur compounds. Both these compound classes can interfere with the gas-chromatographic separation. To remove polar interferences from the extract in view of using HPLC-UVF for subsequent analysis, a chromatographic procedures using disactivated aluminum oxide (10 % water) eluted with hexane as well as silica or modified silica columns can be used (HELCOM, 2012d)

73. Detailed methods for the extraction, clean-up and determination of parent PAHs using High Performance Liquid Chromatography – Fluorescence developed by OSPAR, 2018d) and HELCOM (2012d) are presented in Annex XII and Annex XIII, respectively.

---

[244] OSPAR (2018d). CEMP Guidelines for monitoring contaminants in sediments. Technical Annex 3: Determination of parent and alkylated PAHs in sediments

[245] HELCOM (2012d). Manual for marine monitoring in the COMBINE programme. Annex B-13, Appendix 1. Technical note on the determination of Polycyclic Aromatic Hydrocarbons (PAHs) in sediment

3.4 Protocol for the analysis of PAHs in sediments using GC-MS

74. For the analysis of sediments for PAHs using GC-MS the extraction, concentration and clean-up procedures are similar to the procedures described for the analysis with HPLC. Solvent extraction can be performed on wet or dried sediment. Wet sediment is Soxhlet extracted in two steps: first, using a polar solvent, such as acetone, to extract the water from the sediment, then the extraction continued with a less polar solvent or solvent mixture (e.g., acetone/hexane). Dry sediments can be Soxhlet extracted using medium-polar solvents such as dichloromethane or toluene, or mixtures of polar and non-polar solvents (OSPAR 2018d, HELCOM 2012d).

75. When the extraction is completed, the extract is evaporated with a rotary evaporator to a volume of about 15 ml (the temperature of the water bath does not exceed 30 °C). The extract is dried with anhydrous sodium sulfate and transferred in a graduated tube and concentrated down to 4 to 5 ml using a flow of clean nitrogen. For GC-MS analysis sulphur should be removed from the extracts in order to protect the detector. This can be achieved by the addition of copper powder, wire or gauze during or after organic solvent extraction. Ultrasonic treatment might improve the removal of sulphur (OSPAR 2018d, HELCOM, 2012d).

76. Detailed methods for the extraction, clean-up and determination of PAHs using GC - MS developed by (OSPAR, 2018d) and HELCOM (2012d) are presented in Annex XII and Annex XIII respectively.

3.5 Protocol for the normalization of organic contaminants using Total Organic Carbon (TOC)

77. Normalisation is defined as a procedure to adjust contaminant concentrations for the influence of the natural variability in sediment composition, grain size, organic matter and mineralogy. Most natural and anthropogenic substances, metals and organic contaminants, show a much higher affinity to fine particulate matter compared to the coarse fraction Grain size and organic matter are important factors controlling the distribution of natural and anthropogenic components in sediments. Therefore, normalizing contaminant's data for the effects of grain size or organic carbon is used to allow meaningful comparisons of the occurrence of substances in sediments of variable bulk properties (OSPAR, 2018b).

78. In the European Commission's Guidance Document No: 25 on chemical monitoring of sediment and biota under the Water Framework Directive (EC, 2010[246]), is mentioned that organic contaminants in sediment can be normalized using the total organic carbon (TOC) concentration, because organic matter coatings of fine particles is more effective in bounding lipophilic substances such as chlorinated compounds and PAHs. It is suggested that usually coarser (sand) sediments are less important carriers of lipophilic substances because of their smaller relative surface area. Therefore, it is possible to use the ratio of [concentration of the organic compound]/[TOC] as a normalised value.

79. In many cases the mobility and partitioning of organic contaminants in the environment can be predicted based on their partitioning into the bulk organic carbon in the sediment, which may be presented using different normalizers (Total Organic Carbon - TOC; Elemental Organic Carbon - EOC; particulate organic carbon - POC; loss-on-ignition - LOI). However, Kestern and Smedes (2002) underline that because organic contaminants may enter the marine environment via different pathways,

[246] EC (2010). Guidance Document No: 25 Guidance on chemical monitoring of sediment and biota under the Water Framework Directive

"the key issue for normalization is thus proper characterization of the Organic Matter by as many parameters as possible. The types of information that can be obtained by the utilization of at least the few key parameters are often complementary and extremely useful, considering the complexity and diversity of Organic Matter encountered in the sediment environment." They also note that "Due to its variability, Organic Matter will occur in both the fine and the coarse sediment fraction. Unlike Al in the case of metals, some Organic Matter in the coarse fraction may contribute to the affinity for organic contaminants as a co-factor as well, albeit of limited environmental significance."

80. Therefore, the use of TOC as a normalizing factor should be used cautiously and only if field data support the usefulness of normalizing organic contaminants concentrations, as the means to enhance environmental information for pollution assessment. Normalization to TOC is not a mandatory information to be reported to UNEP/MAP and is up to country to decide if it will be done. However, Parties are encouraged to analyse TOC in sediments as an additional information, which could be used in better understanding of the pollution processes in the areas under investigation in the framework of IMAP.

a) TOC analysis with Carbon Analyser

81. Total Carbon (inorganic and organic) in sediments can be determined with a Carbon Analyser. The sample is injected into a heated reaction chamber packed with an oxidative catalyst (Pt/Al_2O_3) the water is vaporized and both organic and inorganic carbon are oxidized to CO_2, which is measured by means of an Infrared (IR) analyser. Then the inorganic carbon is measured separately, by acidifying the sediment sample with HCl acid at pH <3 and all carbonates are transformed to CO_2 measured in the IR analyser. TOC can be calculated as the difference Total Carbon – Inorganic Carbon. Alternatively, inorganic carbonates are converted to CO_2 with acid, which is removed by purging before the sample injection. The remaining sample contains only the organic carbon fraction of total carbon, which is measured in the IR analyser.

b) TOC analysis with wet oxidation

82. The wet oxidation technique is the complete oxidation of organic carbon using $K_2Cr_2O_7$ and concentrated H_2SO_4 and the titration of excess dichromate with 0.5N ferrous ammonium sulphate solution to a sharp one drop end point (Schumacher, 2002[247]). The method is based on the Walkley and Black (1934[248]) protocol as modified and described by Nelson and Sommers (1996[249]).

83. 0.5 g of dried sediment is placed in a 500 ml Erlenmeyer flask and 10 ml of 1 N $K_2Cr_2O_7$ solution and 20 ml of concentrated H_2SO_4 are added and mixed for 20 min. The mixture is diluted to 200 ml volume with distilled water and 10 ml of 85% H_3PO_4, 0.2 g NaF and 15 drops of diphenylamine indicator. The solution is back titrated with 0.5 N ferrous solution.

Recommended Method on
MICROWAVE DIGESTION OF MARINE SAMPLES
FOR THE DETERMINATION OF TRACE ELEMENT CONTENT

TABLE OF CONTENTS

NOTE: This method is not intended to be an analytical training manual. Therefore, the method is written with the assumption that it will be performed by formally trained analytical chemist. Several stages of this procedure are potentially hazardous, especially stages with HF; users should be familiar with the necessary safety precautions.

In addition, the IAEA's recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method, they shall not be used as absolute QC acceptance criteria.

1. SCOPE

The method here below describes the protocol for dissolution of samples from marine origin. Digests are suitable for analyses of total content of trace element in sediment and biological material.

The goal of this method is the total sample decomposition with the judicious choice of acid combinations this is achievable for most matrices. The selection of reagents which give the highest recoveries for the target analytes is considered the optimum method condition.

The recommended protocol is mainly based on the EPA 3052 method; users are encouraged to consult this document (EPA, 1996).

2. PRINCIPLE

The grinded and dried samples are solubilized in an acid mixture using microwave oven apparatus.

The use of hydrofluoric acid allows the decomposition of silicates by reaction of F with Si to form the volatile SiF4. The excess of hydrofluoric acid is either neutralized by boric acid, or digests are evaporated to dryness depending on the method used to analyze samples.

3. SAMPLE PRE-TREATMENT

Sediment samples are prepared following the recommendations of UNEP (2005).

Marine organisms are prepared following the recommendations of UNEP (1984, 1994).

4. REAGENTS

The reagents used shall meet the purity requirement of the subsequent analyses

4.1. ULTRAPUR WATER (type MilliQ).
4.2. NITRIC ACID 65%.
4.3. HYDROFLUORIC ACID.
4.4. HYDROCHLORIC ACID.
4.5. BORIC ACID.
4.6. HYDROGEN PEROXIDE.

5. MATERIAL

5.1. MICROWAVE APPARATUS

The microwave decomposition system should be temperature controlled. The temperature sensor should be accurate at ±2.5°C. The calibration of the temperature sensor should be done at least once a year, preferably by the maintenance service of the manufacturer.

The microwave unit should be corrosion resistant.

The unit cavity should be well ventilated and connected to fume cleaner or special neutralizing system.

The method requires microwave transparent and acid resistant material (i.e. PFA, TFM) to be used as reactor. The minimal volume of the vessels should be 45 ml and it should be able to work under the pressure of 800PSI. the reactor system should be equipped with a pressure relief system.

5.2. ANALYTICAL BALANCE with 0.001 g precision at least.
5.3. FUME HOOD.
5.4. LAMINAR FLOW HOOD.
5.5. VOLUMETRIC CONTAINERS of 50 ml or 100 ml in polypropylene.
5.6. WEIGHING CUP in polyethylene.
5.7. PLASTIC SPATULAS.

6. PROCEDURE

6.1. All PLASTIC MATERIAL (i.e. volumetric, weighing cup…) should be acid cleaned by soaking in laboratory soap (or 10% alcohol) for at least 24h, followed by 24h of soaking in 10% nitric acid. Stronger acid cleaning protocol could be applied depending on the requirement of the subsequent analyses.
6.2. MICROWAVE VESSELS should be at least cleaned after each use by running the same microwave program used for samples with 5 ml of HNO_3. If the risk of cross contamination is high (i.e. running sandy sediment after organic rich sediment) and/or in the case of long storage, the vessels should be cleaned twice. If available, an acid cleaner

(using acid vapors) can be used as a final cleaning stage. After cleaning, the vessels should be carefully rinsed with water and dried under a laminar flow hood. If a laminar flow hood is not available, vessels should be kept locked in double plastic bag; date of storage should be mentioned on the second bag.

6.3. Accurately weigh 0.1 to 0.5 g of well mixed sample in the microwave vessel.

6.4. In a fume hood, add 5 ml of nitric acid and 2 ml of hydrofluoric acid, close vessels with caps, then it is recommended to let samples react for at least 1 hour (or more if possible). Protect vessels by covering them with plastic bags or place them in a laminar flow hood compatible with acid fume. The quantity of hydrofluoric acid depends on the expected content of silicon dioxide, samples with low concentrations of silicon dioxide (< 10% like plant material to 0% like biological sample) may require less hydrofluoric acid (0.5 ml to 0 ml). Examples of acid quantities for different matrix are listed in table below.

	HF (ml)	HNO_3 (ml)	HCl (ml)	H_2O_2 (ml)	Boric (g)
Sediment	2	5	2 or 0	2	0.8
Fish	0	5	2 or 0	2	0
Sea plant	0.5	5	2 or 0	2	0

6.5. After room temperature pre-digestion, add 2 ml of hydrogen peroxide and close the reactors as recommended by the microwave manufacturer.

NOTE: The quantity and ratio of reagent can be adapted on a performance based judgment (i.e. visual total digestion, certified reference material results).

- In case of a sample containing high calcium carbonate, the hydrofluoric acid content can be set to 0 to avoid precipitation of insoluble CaF.
- A two stage digestion, using half of the hydrofluoric acid at the first stage and half at the second, could increase recovery and help achieving total decomposition.
- Additional reagent can be added depending on the sample composition to achieve complete dissolution. For example, 2±2 ml of HCl can be added to help the stabilization of As, Sb, Hg, Fe and Al at high level; however HCl might increase analytical difficulties for some techniques (i.e. ICP-MS) (Kingston 1997)
- Only one acid mixture or quantity should be used in a single batch, in the microwave, to insure consistent reaction conditions between all vessels and monitored conditions. This limitation is due to the current practice of monitoring a representative vessel, and applying a uniform microwave field to reproduce these reaction conditions within a group of vessels being simultaneously heated.

6.6. Place the closed reactor in the microwave apparatus, connect temperature and pressure control as specified by the manufacturer. The samples should be heated at 180°C

(minimum) in about 6 minutes and the temperature maintained for at least 10 minutes. The total decomposition is primarily controlled by maintaining samples at 180°C for 10 minutes. The ramping profile can be adapted, especially for safety purpose when very reactive samples are decomposed (i.e. biological material). In that case, it is recommended to increase the ramping time to 10 or 15 minutes. If possible, record temperature and pressure profile. In most samples matrices, pressure should peak between 5 and 15 minutes; profiles can be used to optimize temperature program.

6.7. At the end of the temperature profile, let the sample cool until the inside temperature goes down to 60°C, then remove the reactors from the microwave and place them in a ventilated fume hood. The pressure is carefully released following the manufacturer's instruction and reactors are opened.

6.8. In the case of removal of hydrofluoric acid excess with boric acid, 0.8 g of boric acid and 15 ml of water are added in the vessel. The quantity of boric acid is proportional to the quantity of hydrofluoric acid (usually 0.4 g for 1 ml should be sufficient). The vessels are closed again and run in the microwave with a program that heat samples at 170°C in 10 minutes and maintain this temperature for 10 minutes.

6.9. At the end of the temperature profile, let the sample cool until inside the temperature goes down to 60°C, then remove the reactors from the microwave and place them in a ventilated fume hood. The pressure is carefully released following the manufacturer's instruction and reactors are opened. Transfer the samples in a volumetric container and dilute them to a known volume (or a known weight, this requires to record the tare of each container before).

NOTE: An excess of boric acid will produce cloudy solutions, this might cause problem with sample introduction system of ICP. The use of boric acid will prevent measurement of boron, and possible bias introduced should be carefully investigated.

- If the use of boric acid is not possible, or if it is necessary to reduce the concentration of acid in final solutions, digest can be evaporated to incipient dryness on a hot plate at about 140°C. This stage should be performed in a controlled environment to avoid contamination and acid vapour should be treated. Some microwave oven apparatus can perform evaporation. The residue is then diluted to a known volume in nitric or hydrochloric diluted solution (usually 2% v/v) depending on the subsequent analytical method used.
- In case of insoluble precipitate or residue some extra steps can be performed like the addition of 2 ml of perchloric acid to the solution before evaporation, but this requires doing the evaporation under a specific hood for safety reason. Another option is the addition of 2 ml of concentrated hydrochloric acid, evaporation to near dryness, addition of concentrated nitric acid, evaporation to near dryness and dilution in known volume in 2% nitric acid solution.

Most samples will be totally dissolved by this method with the judicious choice of the acid combinations. A few refractory sample matrix compounds, such as TiO2, alumina, and other oxides may not be totally dissolved, and in some cases may sequester target analyte elements.

7. QUALITY CONTROL

7.1. Each microwave batch should contain at the minimum one certified reference material of representative matrix.

7.2. A duplicate or triplicate sample should be processed on a routine basis. A duplicate sample should be processed with each analytical batch or every 10 samples. A duplicate sample should be prepared for each matrix type (i.e. sediment, sea plant, etc.).

7.3. A spiked sample should also be included whenever a new sample matrix is being analyzed, especially if no certified reference material is available for that matrix.

7.4. Blank samples should be prepared using the same reagents and quantities used in sample preparation, placed in vessels of the same type, and processed with the samples. Each microwave batch should contain at least two blank samples.

CEMP Guidelines for Monitoring Contaminants in Sediments

(OSPAR Agreement 2002-16)

Technical Annex 6: Determination of metals in sediments – Analytical methods

CEMP Guidelines for Monitoring Contaminants in Sediments

(OSPAR Agreement 2002-16)

Technical Annex 6: Determination of metals in sediments – analytical methods

1. Introduction

This technical annex provides advice on the determination of metals (including metalloids and some non-metals like Se) in whole sediment and in sieved fractions. Determinations of trace metals can be achieved by acid digestion of the sediment followed by analysis of the digest solution by spectroscopic or spectrometric methods, or non-destructive techniques such as X-ray fluorescence analysis (XRF), instrumental neutron activation analysis (INAA) etc. The guidelines are intended to assist analytical chemists both in starting up metals analyses in sediments, and to those already performing such analyses. They do not provide full detail on specific laboratory procedures. Further guidance may be sought from specialised laboratories and publications (e.g. Loring and Rantala., 1991; Popek, 2003) or general guidance for selection of analytical methods (e.g. Larsen et al., 2011). Analyses should be carried out by experienced staff and the procedure validated.

Trace metals may occur in both fine and sand fractions of sediments. However, most natural and anthropogenic substances (metals and organic contaminants) show a much higher affinity to fine particulate matter than the coarse fraction. Iron and manganese oxy-hydroxide coatings, and constituents such as organic matter and clay minerals, contribute to the affinity for contaminants for this fine material.

Total methods, such as procedures involving total dissolution of sediment samples with hydrofluoric acid (HF) prior to analysis, or non-destructive methods without digestion such as neutron activation analysis (INAA) and X-ray fluorescence analysis, determine total trace metal contents in the whole sediment sample. In contrast, methods using a partial digestion with only strong acids, e.g. nitric acid or aqua regia, mainly measure trace metals in the fine fraction, and only extract small amounts of trace metals from the coarse fraction. For fine material, similar results have been obtained using both total and strong partial methods (Smedes et al, 2000; QUASH/QUASIMEME intercalibrations).

2. Sampling, pre-treatment and storage

Sampling sediments for metals analysis should preferably be done using cleaned plastic equipment, but this may not always be possible (e.g. at sea). Where metal sampling gear such as grabs must be used, care must be taken to avoid contamination of the sample, for instance by sub-sampling only sediment that has had no contact with the walls of the sampling device (maintain at least 1cm distance from sides). Sample thickness should be chosen according to the monitoring proposes.

For ordinary surveys, the upper 2 cm of the sediment are sampled, but for other purposes like retrospective surveys, core samples can be taken. If knowledge exists about about the sedimentation rate, the sampling strategy can be based on this (e.g. Wadden Sea sampling of the upper 1 mm).

Sediments can be stored in closed plastic or glass containers. Samples must be sieved at 2 mm as soon as possible after sampling to remove large debris as well as large detritus and benthic organisms.

Otherwise during further sample handling like storage, freezing or ultrasonic treatment, biotic material will deteriorate and become part of the sediment sample. Samples may then be further wet sieved to a smaller size fraction. Further details on sieving procedures are available in the Technical Annex 5: Normalisation of Contaminant Concentrations in Sediments.

For total analysis, metals are usually not very sensitive with regard to storage conditions, so other measured parameters may determine how to store the samples. For total analysis of metals the sample can be stored at 4°C for a few weeks and for extended periods when frozen at –20°C, although direct wet sieving is preferred. For prolonged storage freeze-drying of samples can be considered. In this case contamination and losses of contaminants during freeze-drying have to be checked, in particular for volatile parameters (e.g. volatile organics) to be analysed in the same samples. Air-drying is not appropriate due to high contamination risks. Besides, samples may be difficult to disaggregate and mineral structures may be affected.

Once sieved and dried, samples should be homogenised and ground to a fine powder in a non-contaminating mill (e.g. made of agate or silicon nitride), and stored in plastic or glass containers until analysis.

3. Blanks and contamination

Any contact between the samples and metals should be avoided. If metallic implements are required during sampling (e.g. grab jaws), they should be of stainless steel and contact between the sub-sample and metal should be minimised.

Plastic and glassware should be cleaned using a laboratory washing machine incorporating an acid wash, or by an equivalent cleaning procedure. Some plastic ware may not need to be cleaned before first use for metals work, but this feature must be thoroughly examined (e.g. using acid leaching tests) before proceeding with any real samples.

Blanks should be taken through the whole procedure. In practice, this will generally represent the time from acid addition to a sample container through to the final measurement. There should be at least one analytical blank in a batch of 10-20 samples, representing 5-10% of the sample number.

For core-samples, care should be taken not to contaminate lower samples with upper samples in the process of cutting up the sediment core.

4. Digestion

4.1 Hydrofluoric acid digestion

HF digestions should be performed in polytetrafluorethylene (PTFE or PFA) vessels or equal quality, since the vessel must be metal-free and resist attack by the acid itself. Dried samples (normally 0.2-1g) should be accurately weighed into the vessel. Under fume extraction, the acid(s) are added. Some workers add HF first and leave the mixture to stand overnight, others add HF and nitric acid; others use a perchloric acid mixture etc. In general, the mixtures are left to stand for a period (1 hour – overnight) to avoid problems with violent reactions, which may be prompted by the presence of organic matter in the sediment. Note that perchloric acid and organic matter can promote an explosive reaction, so this acid must be treated with great caution if applied to sediments. Specially designed fume hoods should be used for HF and perchloric acid treatments.

HF is corrosive and toxic. It is therefore necessary to either remove the acid or render it less harmful to the measurement instruments. The acid may either be boiled off, which requires specialised facilities to extract the toxic fumes, or neutralised with boric acid (H_3BO_3), which is itself toxic.

Samples may be digested in a programmable heating block, with HF removal by evaporation. Alternatively, microwave digestions provide a rapid way to digest sediments. Some systems may allow the evaporation of HF, but in general microwaves use closed systems which allow pressure and temperature effects to rapidly dissolve the sediment. The most common methods use polytetrafluorethylene (PTFE or PFA) lined and sealed digestion vessels (Nakashima *et a*l 1988; Loring and Rantala, 1990). Since these closed systems retain the HF, boric acid is added after the HF digestion to complex remaining HF and make the resulting solution less hazardous, as well as preventing aluminium fluoride precipitation. The solution should be made up to volume with ultra pure water and left to stand for at least 24 hours prior to analysis to precipitate excess boric acid. Others use adjusted amounts of boric acid and head the digest to accelerate the process (Maham *et al* 1987). Typical methods are described, for example, in Cook *et al* (1997), Jones and Laslett (1994), Wu et al. (1996), Quelle et al. (2011).

If HF is to be removed by evaporation, care should be taken to ensure that mercury is not lost from sample solutions (Delft and Vos, 1988). It can be difficult to avoid mercury contamination with total digestion, but usually mercury is not bound strongly, so mercury can alternatively be analysed using strong acid digestion or by direct analysis (Taylor et al., 2012).

4.2 Strong acid digestion

Partial digestions follow broadly similar procedures to HF digestions, as above, for example using HNO3 or aqua regia and deionised water to ca. 0.5 g sample.. Microwave digestion is the preferred technique but alternative methods applying high pressure and temperature can be used. The method used needs to be checked. Adequate performance is achieved when digestion dissolves all the Al and Li from the clay fraction. It can easily be tested whether a method meets this requirement through parallel analyses of very fine grained samples by the partial method in use and a total method e.g. HF. If results for Al and Li do not differ significantly, the partial method used is sufficiently strong. To optimise the tests and to further normalise results, sieving to 20 or 63 µm grain size can be used, also reducing problems with detection limits in sandy sediments. A more general discussion on normalization can be found in the Technical Annex 5: Normalisation of Contaminant Concentrations in Sediments.

If the partial method results in lower contents than the total method, the conditions for the partial digestion such as time, temperature, acid concentration etc. need to be adjusted. Usually boiling with aqua regia is insufficient for a complete dissolution of Al. Historically, aqua regia has been used for strong acid digestions, but hydrochloric acid produces interferences for multi-element analysis by ICP and Cd in graphite furnace, so concentrated nitric acid alone may be used as a substitute (Christensen et al., 1982; Krumgalz and Fainshtein, 1989; Koopmann and Prange, 1991). However, collision or reaction cell technology in ICP-MS can be used to reduce the interfering effect of chloride and other multi-element interferences, down to levels of <1% mass overlap for double charged or multi-element species, thus minimising correction formulas for standard mass-corrections.

5. Analysis and detection

Analysis of metals in solution resulting from digestion may be performed by a variety of means, but usually involve spectrometric or spectroscopic detection. Flame or graphite furnace atomic absorption spectroscopy used to be the major method used for analysis of metals (Welz, 1985). Alternatively, non-destructive methods, i.e. XRF (e.g. Jenkins, 1999; Potts, 1992;, Williams, 1987; Bertin, 1984) and INAA (Alfassi, 1998), which do not require a preceding digestion step, can be used. Multielement

techniques like inductively coupled plasma attached to either an emission spectrometer (ICP-AES) or mass spectrometer (ICP-MS) allow much more rapid analysis of a wide range of metals (Kimbrough and Lauenstein, 2006; Duzgoren- Aydin et al., 2011; Castillo et al., 2012).

Interferences in analysis may arise through the presence of other components in the sample. Use of 3-point standard additions may highlight where these occur and can be used to correct for suppression or enhancement effects. Interferences occurring with multi-element analytical techniques can be complex and require skilled personnel to identify and minimise such effects (Cook *et al*, 1997).

Mercury can be detected by fluorescence spectrometry or cold vapour atomic absorption spectrometry. Direct methods for analysing mercury use pyrolysis combined with a gold trap and fluorescence or atomic absorption detection are sensitive enough to measure sediments directly (Maggi et al., 2009; Kelly et al., 2012). ICP-MS is also sufficiently sensitive to measure Hg, but care should be taken about controlling carry over memory effects. It should be ensured that the limits of detection of the analytical technique selected meets the requirements of the respective monitoring programme. Typical detection limits using different methods are given in Table 1.

Table 1: Typical limits of detection for the determination of trace metals with different techniques (in mg/kg d.w.) based on typical sample intakes (0.5 – 1 g)

	Al	Li	As	Cd	Cr	Cu	Hg	Ni	Pb	Zn
AAS / flame	5	0.2		0.5	5	2		5	5	10
AAS / graphite furnace, hydride technique, cold vapour	<1	<1-	0.2	0.02	<1	<1	0.05	<1	<1	-
ICP – AES with hydride generation	10	10	10 1	0.5	1	1	-	2	5	1
ICP – MS	40	0.1	1	0.01	0.2	0.1	0.05	0.2	0.2	2
X-ray fluorescence analysis (XRF)	1000	-	-	-	10	10	-	10	10	20
Neutron activation analysis (INAA)	-	-	0.3	1	0.8	-	0.1	-	-	2
Fluorescence, AAS spectrometry (direct or cold vapour/hydride generation)	-	-	0.2	-	-	-	0.005	-	-	-
Direct Mercury Analyzer (AA)							0.005			

6. Metal speciation

Several methods are in use to examine metal speciation in sediments, mainly by use of sequential extraction (e.g. Gleyzes et al., 2002; Scouller et al., 2006; Sutherland, 2010; Duzgoren-Aydin et al., 2011), but currently also by passive samplers (for metals primarily DGTs) in porewater (Peijnenburg et al., 2014).

7. Limits of detection

The limit of detection for each metal is normally determined by analysing a blank solution (containing acid to the dilution it is present in the sample) at least ten times. The limit of detection is calculated from 3 times the standard deviation of the blank taken through the whole procedure. For typical limits of detection, see Table 1.

8. Calibration and standards

Calibrations are usually performed using multi-element stock solutions, using at least a 4-point calibration covering the range of concentrations expected. Multi-element solutions are commercially available, and may be used provided that they are of a similar matrix to the analyte. A crosscheck solution from a separate batch, or from a different supplier or an internal reference standard, should be used to check the calibration. Differences should not exceed 5%.

For non-destructive methods, appropriate certified reference sediments are required for calibration purposes.

9. Quality assurance

Every determinand should have its own Quality Control and Quality Assessment (QC – QA) scheme that includes regular blanks and calibration checks, the use of internal reference materials and certified reference materials and quality control charts. A system suitability check should be included in each batch to confirm that measuring instrument is operating correctly. In each batch of samples at least one standard addition (from the start of the digestion) should be included to demonstrate that matrix effects do not occur, and also a duplicate sample analysed in a different batch.

At least one laboratory reference material should be included in each batch of samples in order to check the long-term performance. A quality control Shewhart chart should be constructed for selected trace metals. If the warning limits are exceeded, the method should be checked for possible errors. When alarm limits are exceeded, the results should not be reported.

Certified reference materials (CRMs) for sediments are commercially available for both total methods and partial digestion methods. The data provided by such materials provide an independent check on the analytical performance. Table 2 contains information on certified reference materials available for use in marine monitoring.

Table 2: Certified Reference Materials for metals in marine sediments.

Code	Organization	Matrix
BCR 277R	IRMM[1]	Estuarine sediment
BCR 320R	IRMM	Channel sediment
BCR CC580	IRMM	Estuarine sediment (only Hg and CH_3Hg)
BCR 667	IRMM	Estuarine sediment
HISS-1	NRC[2]	Marine sediment
MESS-3	NRC	Marine sediment
PACS-2	NRC	Marine sediment (Harbour)
SRM 1646a	NIST[3]	Estuarine sediment
SRM 1944	NIST	Marine sediment
SRM 2702	NIST	Marine sediment

[1]IRMM: Institute for Reference Materials and Measurements (Europe)

[2]NRC: National Research Council (Canada)

[3]NIST: The National Institute of Standards and Technology (USA)

Participation in an international proficiency-testing scheme e.g. QUASIMEME is highly recommended to improve comparability between laboratories. Relevant quality assurance data should be reported e.g. to ICES, together with concentration data.

Annex III:

Recommended method for the determination of selected trace element in samples of marine origin by flame atomic absorption spectrometry

Recommended method for the determination of selected trace element in samples of marine origin by flame atomic absorption spectrometry

Marine Environmental Studies Laboratory in co-operation with MED POL

November 2011

Table of Content

NOTE: This recommended method is not intended to be an analytical training manual. Therefore the method is written with the assumption that it will be performed by formally trained analytical chemists.

In addition the IAEA recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method they must not be used as absolute QC acceptance criteria,

The recommended protocol is mainly based on EPA 7000B method and ISO 11047 users are encouraged to consult this documents (US EPA, 2007; ISO 1998).

1. SCOPE:

This recommended method describes a protocol for measurement of Al, Ca, Co, Cr, Cu, Fe, Mg, Mn, Ni, Sr and Zn by flame (direct aspiration) atomic absorption spectrometry. The method is simple, rapid and applicable to a large number of environmental samples. This method is applicable when the element content in the digested solution is above the method limit. This limit will vary with the matrices and instrument model, indicative quantification limits are reported in table 1.

Table 1: Example of lower quantification limit for analyte in reagent water

Element	Lower quantification limit ($mg\ l^{-1}$)
Al	0.5
Ca	0.02
Co	0.06
Cr	0.1
Cu	0.04
Fe	0.05
Mg	0.003
Mn	0.03
Ni	0.07
Sr	0.06
Zn	0.01

2. PRINCIPLE:

The method is based on the atomic absorption spectrometric measurement of the element in the mineralised solutions. In direct-aspiration atomic absorption spectrophotometry, the solution is aspirated and atomized in a flame. A light beam from a hollow cathode lamp or an electrodeless discharge lamp is directed through the flame into a monochromator, and onto a detector that measures the amount of absorbed light. Absorption depends upon the presence of free unexcited ground-state atoms in the flame. Because the wavelength of the light beam is characteristic of only the metal being determined, the light energy absorbed by the flame is a measure of the concentration of that metal in the sample. This principle is the basis of atomic absorption spectrophotometry.

3. SAMPLE PRE-TREATMENT:

Samples are prepared following the recommended method for microwave digestion of marine samples for determination of trace element content. (IAEA recommended method, 2011).

4. REAGENT:

All reagent used should be free of contamination of analyte of interest

4.1. Water: Reagent water (referenced also as water in the text) should be free of contamination

4.2. Caesium chloride solution, 4g l^{-1}: Dissolve 4g of CsCl of at least 99.999% purity in reagent water to 1 liter.

4.3. Caesium-Lanthanum solution: weigh 5.865g of La_2O_3 and 12.67g of CsCl in 100ml container, add 50ml of reagent water and 25ml of HCl and dilute to 100ml. Commercial solution specially produced for AAS may be used.

4.4. Commercial standard solution 1000µg ml^{-1}: Use a certified reference material solution; this solution should be accompanied by a certificate that should include at the minimum the traceability of the certified concentration as well as the expiration date. The density of the solution or the certified content in mg kg^{-1} should also be defined to allow preparation of the calibration solution by weighing.

5. MATERIAL:

This section does not list common laboratory glassware

5.1. Atomic absorption spectrophotometer: This shall be equipped with: a hollow cathode lamp or an electrode-less discharge lamp appropriate to the element of interest (operated at the current recommended for the lamp by the instrument manufacturer), a background correction system, a burner suitable for an air/acetylene or nitrous oxide/acetylene flame (operated following the manufacturer's instructions). Deuterium background correction is the minimum technical specification acceptable for background correction for the measurement wavelengths below 350 nm.

5.2. Glassware: All glassware, polypropylene, or fluorocarbon (PFA or TFM) containers, including sample bottles, flasks and pipets tips, should be washed in the following sequence -- 24h soaking in laboratory soap (or 10% alcohol) followed by 24h soaking in 10% nitric acid, followed by 10% soaking in water, final rinse in water, drying under laminar flow hood. Cleaned items should be kept in double sealed plastic bags.

If it can be documented through an active analytical quality control program using spiked samples and method blanks that certain steps in the cleaning procedure are not needed for routine samples, those steps may be eliminated from the procedure (i.e. For the levels measured by flame AAS some sterile plastic containers are sufficiently free of contamination in certain analytes.)

5.3. Pipettes: microliter pipettes size ranging from 50 to 10000µl as needed. The accuracy and precision of the pipettes used should be checked as a routine every 6 months and obtained results should be compared with the individual certificates.

5.4. Volumetric containers preferably in polypropylene of a suitable precision and accuracy

6. INTERFERENCES:

6.1. The most troublesome type of interference in atomic absorption spectrometry is usually termed “chemical” and is cause by lack of absorption of atoms bound in molecular combination in the flame. This phenomenon can occur when the flame is not sufficiently hot to dissociate the molecule. The addition of chemical buffer (i.e. Lanthanum or calcium) or the use of nitrous oxide/acetylene gas mixture will help to prevent this interference.

6.2. The presence of high dissolved solids in the sample may result in interference from non-atomic absorbance such as light scattering. In the absence of background correction, this can result in false positive, signal contribution from uncorrected background which cannot be compensated by the method of standard addition.

6.3. Ionisation interference occurs when the flame temperature is sufficiently high to generate the removal of an electron from a neutral atom, giving a positively charged ion. This type of interference can generally be controlled by the addition of a large excess (~1mg l-1) of an easily ionized element such as K or Cs.

6.4. Spectral interference can occur when an absorbing wavelength of an element present in the sample, but not being determined, falls within the width of the absorption line of the element of interest. This type of interference may sometimes be reduced by narrowing the slid width.

Specific conditions applied to individual anaytes in case of known interferences are displayed in table 2.

Table 2: Instrument parameter

Element	Wavelength (nm)	Flame type	Chemical buffer*	Background	Typical calibration range (mg l^{-1})
Al	324.7	acetylene/NO2	Caesium chloride	Deuterium	1.5-40
Ca	422.7	acetylene/NO2	Caesium Lanthanum		0.02-1.2
Co	240.7	acetylene/air		Deuterium	0.06-4
Cr	357.9	acetylene/NO2			0.3-6
Cr	357.9	acetylene/air	Caesium chloride		0.1-6
Cu	324.7	acetylene/air		Deuterium	0.04-3
Fe	248.3	acetylene/air	Caesium chloride	Deuterium	0.05-3
Mg	285.2	acetylene/air	Caesium Lanthanum	Deuterium	0.003-0.3
Mn	279.5	acetylene/air	Caesium Lanthanum	Deuterium	0.03-3
Ni	232.0	acetylene/air		Deuterium	0.07-4
Sr		acetylene/NO2	Caesium chloride		0.06-5
Zn	213.9	acetylene/air		Deuterium	0.01-1.5

* see 4.2, 4.3and 7.4 for use of chemical buffer

7. PROCEDURE:

7.1.Sample solution: Use sample prepared following the recommended method for digestion of marine samples for the determination of trace metal (IAEA, 2011)

7.2.Blank solution: Prepare at least two blank solutions with each batch of sample using same procedure than for samples

7.3.Preparation of calibration solutions:

7.3.1. Before each batch of determination prepare by appropriate dilution of 1000µg ml^{-1} stock standard solution (4.4) at least 4 standard solutions and one calibration blank solution covering the appropriate range of the linear part of the curve. The calibration standards and calibration blank should be prepared using the same type of acid or combination of acids and at the same concentration as will result in the test portion.

7.3.2. Calibration solutions should be prepared fresh each day.

7.3.3. If necessary intermediate stock standard solutions can be prepared in 10% nitric acid, these solutions should be prepared monthly.

7.3.4. All volumetric material (pipettes and containers) should be of appropriate precision and accuracy, if not available standard solution can be prepared by weighing.

7.3.5. Example of calibration curve are given in table 2.

7.4. Special case: Use of chemical buffer. If a chemical buffer is added, it should be at the same concentration as in the sample solution (7.1), the blank (7.2), calibration blank and standard solutions (7.3) following the recommendation of table 2.

For CsCl add 5ml of 4g l^{-1} for 50 ml of solution (4.2)

For CsLa solution add 0.5ml for 50ml of solution (4.3)

The chemical buffer will be added to a separate portion of sample and blank solutions that will need to be diluted to a known volume.

7.5. Calibration

7.5.1. Set up the atomic absorption spectrometer according to the manufacturer's instructions at the appropriate wavelength using appropriate conditions (see table 2), and with the suitable background correction system in operation.

7.5.2. Aspirate a calibration solution (7.3) and optimize the aspiration conditions, burner height and flame conditions to get the maximum signal.

7.5.3. Adjust the response of the instrument to zero absorbance whilst aspirating water

7.5.4. Aspirate the set of calibration solutions in ascending order and, as a zero member, the blank calibration solution (7.3).

NOTE: Care should be taken to ensure that, when using the more concentrated standards, the absorbance is < 1, and preferably not more than 0,6.
The calibration curve is automatically plot from instrument software. The obtained curve should be linear with r<0.995.
To correct for the instrumental drift the calibration should be performed every 20 samples or if the calibration verification has failed (7.8.1).

7.6. Aspirate blank (7.2) and sample solutions (7.1) and record their concentrations calculated by software using the calibration curve.

7.7. If the concentration of the test portion exceeds the calibration range dilute the test portion with the blank solution accordingly.

As an option to avoid too big dilution factors and/or to avoid a diluting large number of solutions, if all solutions are exceeding the calibration range, the burner can be turned from 0 to 90° to decrease the instrument’s sensitivity. New calibration standard solutions should be prepared to match the sample range and the procedure should be repeated from (7.3).

7.8. Quality control solutions: Quality control solutions as describe below should be measured during the run.

7.8.1. **Initial Calibration Verification ICV**:

After initial calibration, the calibration curve must be verified by the use of initial calibration verification (ICV) standard.

The ICV standard is a standard solution made from an independent (second source) material at or near midrange. This solution as a calibration standard is prepared using the same type of acid or combination of acids and at the same concentration as will result in the test portion. If a chemical buffer is necessary it should be added in the ICV.

The acceptance criteria for the ICV standard must be ±10% of its true value

If the calibration curve cannot be verified within the specified limits, the cause must be determined and the instrument recalibrated before samples are analyzed. The analysis data for the ICV must be kept on file with the sample analysis

The calibration curve must also be verified at the end of each analysis batch and/or after every 10 samples. If the calibration cannot be verified within the specified limits, the sample analysis must be discontinued, the cause determined and the instrument recalibrated. All samples following the last acceptable test must be reanalyzed.

7.8.2. **Blank solution** (7.2): Maximum allowed blank concentration should be well documented and if blank solution exceeds this value all samples prepared along the contaminated blank should be prepared again and reanalysed.

7.8.3. **Post digestion spike**

Each unknown type of sample should be spike to check for potential matrix effect.

This spike is consider as a single point standard addition, and should be performed with a minimum dilution factor. The recovery of spike calculated as equation 1 should be 85-115%. If this test fails it is recommended to run analyses with standard addition method.

Spike solution: mix a fixe volume (V1) of sample solution, and a known volume (V2) of a standard solution of a known concentration (Cstandard)

Unspike solution: mix same fixe volume (V1) of sample solution, and same volume (V2) of reagent water

Measure concentration C (mg l^{-1}) in both solutions on the calibration curve (7.6), and calculate recovery as:

Equation 1 $$Cspike = \frac{Cstandard \times V2}{(V1+V2)}$$

Equation 2 $$R = \frac{C\ Spike\ Solution - C\ Unspike\ solution}{Cspike} \times 100$$

To be valid concentrations of spike and unspike solutions should be in the linearity range of the calibration curve and the Spike concentration (equation 1) should be in the range of 50-150% of the concentration of unspike solution.

7.8.4. **Dilution test**:

If the analyte concentration is sufficiently high (minimally, a factor of 10 above the lower limit of quantitation after dilution), an analysis of a 1:5

dilution should agree within ±10% of the original determination. If not, then a chemical or physical interference effect should be suspected, and method of standard addition is recommended.

7.8.5. **Certified Reference Material**:

At least one certified reference material of a representative matrix should be prepared with each batch of sample, the calculated result should fall in the value of the certificate within the coverage uncertainty.(Linsinger, 2010), to show evidence of unbiased result.

Results of CRM should be recorded for quality control purpose and plot in control chart (UNEP/IOC/IAEA 1994).

An example of sequence order with recommended criteria and actions is given in table 3.

8. CALCULATION OF RESULTS:

Results are calculated with equation 3

Equation 3: $w(m) = \frac{(\rho 1 - \rho 0)}{\mathrm{m}} \times f \times V \times R$

w(m) mass fraction of element m in the sample in mg kg^{-1}
ρ1: concentration of element m in milligrams per liter as measured in the sample solution
ρ0: concentration of element m in milligrams per liter as measured in the blank solution
f: is the dilution factor calculated as

$$f = \frac{final\ volume}{initial\ volume}$$

or equal to 1 if ρ1 is determined in undiluted solution
R: recovery calculated using CRM (see 7.8.5) or pre digestion spike

9. EXPRESSION OF RESULTS:

The rounding of values will depend of the uncertainty reported with the result; in general for this method no more than two significant figures will be reported.

Uncertainty component should be reported with all results. (ISO 2005, Nordtest 2004)

Example : w(Zn) = 8.5 ± 1.2 mg kg^{1}

Table 3: Example of an analytical sequence:

Solutions Description	Performance	Action
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1 -4	r>0.995	recalibrate in the linearity range
ICV	±10% of true value	Stop until resolve
Sample blank	< maximum allowed blank value	
CRM	Fall in certificate value within coverage uncertainty, or fall within acceptable criteria of the QC chart	Stop until resolve, check Matrix spike and run again with standard addition method if necessary
Matrix Spike	recovery 100% ± 15%	switch to standard addition, keep record for future analyses of the same matrix
Dilution Test	sample 1 = 5x sample 1 diluted 5x within 10%	switch to standard addition, keep record for future analyses of the same matrix
Unknown Sample 1-10	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute
ICV	±10% of true value	Stop until resolve
Unknown Sample 11-20	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1 -4	r>0.995	recalibrate in the linearity range
ICV	±10% of true value	Stop until resolve

<u>NOTE:</u> This recommended method is not intended to be an analytical training manual. Therefore the method is written with the assumption that it will be performed by formally trained analytical chemist.
In addition, the IAEA recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method they must not be used as absolute QC acceptance criteria.

The recommended protocol is mainly based on EPA 7010 method and ISO 15586 users are encouraged to consult this documents (US EPA, 2007; ISO 2003)

1. SCOPE:

This International Standard includes principles and procedures for the determination of trace levels of: As, Cd, Co, Cr, Cu, Ni, Pb, and V in samples from marine origin, using atomic absorption spectrometry with electro thermal atomization in a graphite furnace. The method is applicable to the determination of low concentrations of elements. The detection limit of the method for each element depends on the sample matrix as well as the instrument, the type of atomizer and the use of chemical modifiers. Table 1 gives approximate working range and characteristic masses.

Table 1 Approximate characteristic masses and typical working range using 20µl sample volume

Element	Characteristic mass M_0* pg	Working range ng ml^{-1}
As	15	5-50
Cd	0.8	0.2-2
Co	10	3-30
Cr	3	2-20
Cu	10	3-30
Ni	13	5-50
Pb	15	5-50
V	35	10-100

**The characteristic mass (m_0) of an element is the mass in pg corresponding to a signal of 0.00044 unity using peak area as integration*

2. PRINCIPLE:

An aliquot of sample solution (5-50 µL) is introduced into a graphite tube of the GF AAS and atomized by rapid heating at high temperature. A light beam is directed through the graphite tube, into a monochromator, and onto a detector that measures the amount of light absorbed by the atomized element in the tube. Each metal has its own characteristic wavelength therefore a source hollow cathode lamp composed of that element is used. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

3. SAMPLE PRE-TREATMENT:

Samples are prepared following the recommended method for microwave digestion of marine samples for determination of trace element content. (IAEA recommended method, 2011)

4. REAGENTS:

4.1. Water: Reagent water (referenced also as water in the text) should be free of contamination

4.2. Concentrated acid solution as used for sample preparation (section 3)

4.3. Commercial standard solution 1000µg ml^{-1}: Use certified reference material solution; this solution should be accompanied by a certificate that should include at least the traceability of the certified concentration as well as the expiration date. The density of the solution or the certified content in mg kg-1 should also be defined to allow preparation of calibration solution by weighing.

4.4. Calibration solutions: Prepare calibration solutions from the standard solutions (4.3) by appropriate dilution. Intermediate standard solutions should be prepared in 2% (v/v) nitric acid. For calibration solution use the same amount of acid as that of the samples solutions.

Calibration solutions below 1 mg/l should not be used for more than one month, and those below 100 µg/l should not be used for more than one day.

4.5. Blank calibration solution: Prepare a blank calibration solution in the same way as the calibration solution but without adding standard. The final amount of acid will be the same as that of the sample solutions.

4.6. Palladium nitrate/magnesium nitrate modifier

Pd(NO3)2 solution is commercially available (10 g/l). Dissolve 0,259 g of Mg(NO3)2·6H2O in 100 ml of water. Mix the palladium nitrate solution with twice as much magnesium nitrate solution. 10 µl of the mixed solution is equal to 15 µg Pd and 10 µg Mg(NO3)2. The mixture is also commercially available.

Prepare a fresh solution monthly.

4.7. Magnesium nitrate modifier

Dissolve 0,865 g of Mg(NO3)2·6H2O in 100 ml of water. 10 µl of this solution is equal to 50 µg Mg(NO3)2.

4.8. Ammonium dihydrogen phosphate modifier

Dissolve 2,0 g of NH4H2PO4 in 100 ml of water. 10 µl of this solution is equal to 200 µg NH4H2PO4.

4.9. Ammonium dihydrogen phosphate/magnesium nitrate modifier

Dissolve 2,0 g of NH4H2PO4 and 0,173 g of Mg(NO3)2·6H2O in 100 ml of water. 10 µl of this solution is equal to 200 µg NH4H2PO4 and 10 µg Mg(NO3)2.

4.10. Palladium/Ammonium dihydrogen phosphate/magnesium nitrate modifier

Mix 2ml of Pd(NO3)2 solution is commercially available (10 g/l), 2ml of Mg(NO3)2 solution prepared as (4.7), 0.5ml of NH4H2PO4 prepared as (4.8) and dilute with water to 10ml. 4µl of this solution is equal to 8µg of Pd, 4µg of $Mg(NO_3)_2$ and 4µg of NH4H2PO4.

4.11. Nickel modifier

Dissolve 0,200 g of nickel powder in 1 ml concentrated nitric acid and dilute to 100 ml with water. 10 µl of this solution is equal to 20 µg Ni. Solutions of Ni(NO3)2 are also commercially available.

4.12. Iridium solution 1000µg ml^{-1}

Use commercial solution (standard)

4.13. Argon

5. MATERIALS:

5.1. Glassware: All glassware, polypropylene, or fluorocarbon (PFA or TFM) containers, including sample bottles, flasks and pipettes tips, should be washed in the following sequence -- 24h soaking in laboratory soap (or 10% alcohol) followed by 24h soaking in 10% nitric acid, followed by 10% soaking in water, final rinsing in water, drying under laminar flow hood. Cleaned items should be kept in double sealed plastic bags

5.2. Pipettes: microliter pipettes size ranging from 50 to 10000µl as needed. The accuracy and precision of the pipettes used should be checked as a routine every 6 months and the obtained results should be compared with the individual certificates.

5.3. Volumetric containers preferably in polypropylene of suitable precision and accuracy

5.4. Atomic Absorption Spectrometer equipped with graphite furnace, background correction system and necessary hallow cathode lamp.

5.5. Auto sampler

5.6. Polypropylene cups for automatic sampler cleaned as explained in (5.1)

5.7. Graphite tubes: pyrolytically-coated with platforms, preferably for highly and medium volatile elements, whereas elements of low volatility should be atomized from the wall. Provided satisfactory results are achieved, manufacturer's recommendations regarding the use of graphite tubes and platforms should be followed.

6. INTERFERENCES:

Some sample solutions, may contain large amounts of substances that may affect the results. High concentrations of chloride may cause low results, because the volatility of many elements is increased and analyte loss may occur during the pyrolysis step. Matrix effects may be overcome, partially or completely, by the optimization of the temperature program, the use of pyrolytically-coated tubes and platforms, the use of chemical modifiers, the standard addition technique and the use of background correction.

7. CHEMICAL MODIFICATION:

Chemical modifiers are used to overcome spectral and/or non-spectral interferences in a sample (matrix effects). In general, the aim of chemical modification is to allow a pyrolysis temperature that is high enough to remove the bulk of concomitants before the atomization step. In order to ascertain that the modification works, the spike procedures is performed with and without the addition of a chosen chemical modifier and recovery are compared

Spike experiment:

Spike solution: mix a fixe volume (V1) of sample solution, and a known volume (V2) of a standard solution of a known concentration (Cstandard)

Unspike solution: mix same fixe volume (V1) of sample solution, and same volume (V2) of reagent water

Measure concentration C (mg l^{-1}) in both solutions on the calibration curve, and calculate recovery as:

Equation 1 $$Cspike = \frac{Cstandard \times V2}{(V1+V2)}$$

Equation 2 $$R = \frac{C\ Spike\ Solution - C\ Unspike\ solution}{Cspike} \times 100$$

To be valid concentrations of spike and unspike solutions should be in the linearity range of the calibration curve and Spike concentration (equation 1) should be in the range of 50-150% of the concentration of unspike solution. The recovery should be 100 ± 15%

In Table 2 some recommendations of chemical modifiers are given.

Other chemical modifiers may be used if they show consistent results. Graphite tube can also be pretreated with Iridium (Vasileva 2001) as following:

Inject 50µl of the solution and run the temperature program below

Step	Temperature (°C)	Ramp Time (s)	Hold Time (s)
1	100	5	30
2	1200	20	5
3	100	5	2
4	2500	2	10

Repeat this 3 times, the coating is stable for about 200 injections and can be repeated

If chemical modifiers are used, add them to test samples, sample blank solutions, calibration solutions, and blank calibration solutions. Preferably inject the modifier solution with the auto sampler directly into the atomizer after the sample is delivered.

Table 2 Recommended chemical modifiers

Element	Chemical modifier	Amount* µg
As	Pd + $Mg(NO_3)_2$ or $NH_4H_2PO_4$	15+10 200
Cd	Pd + $Mg(NO_3)_2$+$NH_4H_2PO_4$ or Ir coating	8+4+4
Co	Pd + $Mg(NO_3)_2$	15+10
Cr	$Mg(NO_3)_2$	50
Cu	None	
Ni	$Mg(NO_3)_2$	50
Pb	Pd + $Mg(NO_3)_2$+$NH_4H_2PO_4$ or Ir coating	8+4+4
V	None	

**These amounts are only recommendation, significantly lower amounts may be required in some atomizers, see also recommendations from instrument manufacturers.*

8. PROCEDURE

8.1. Switch on the instrument and perform the optimization according to the manufacturer's instructions. Install an appropriate graphite tube, and set up the auto sampler.

8.2. Program the graphite furnace and the auto sampler. Examples of temperature program are given in table 3.

Note: Method for specific element and matrix should be developed and all necessary information should be stored with at least:

- *Temperature program*
- *Matrix modifier*
- *Type of graphite tube*
- *Matrix effect*
- *Type of calibration curve*
- *Typical m_0 obtained with the program*
- *Linearity*

Table 3 Example of temperature program

Element	Cu	Cu	Cd	Cd	Pb	Pb	As	As	Cr	Cr
Sample type	Sediment	Biota	Sediment	Biota	Sediment	Biota	Sediment	Biota	Sediment	Biota
Wavelengt(nm)	327.4	327.4	228.8	228.8	283.3	283.3	193.7	193.7	357.9	357.9
Graphite tube	Partition Tube	Partition Tube	platform	platform	platform	platform	platform	platform	Partition Tube	Partition Tube
Matrix Modifier	none	none	none	Pd,Mg, Amonium Phosphate	none	Pd,Mg ,Amonium Phosphate	Pd,Mg	Pd,Mg	none	none
Peak Measurement	area	area	area	area	area	area	area	area	area	area
M0(pg/0.0044 UA) on standard	13	13	1	1	16	16	15	15	2.5	2.5
Ashing T° (C°)	700	700	300	700	400	925	1400	1400	1100	1100
Atomisation T° (C°)	2300	2300	1800	1900	2100	2200	2600	2600	2600	2600
Remark							Number of Fire is critical	Standard Addition often required. Number of fire is critical	Use peak Height for lower concentration (peak shape)	Standard Addition often required. Use peak Height for lower concentration (peak shape)

8.3. Generality for measurements:

All measurements should be performed with at least duplicate injections of solutions; the relative standard deviation should be less than 5% for a signal above 0.01 unit of absorbance.

It is recommended to work in peak area.

Check the number of firing and change the graphite tube when appropriate, if graphite tube is changed during a run, the instrument needs to be recalibrated.

8.4. Run the calibration:

8.4.1. **Standard calibration technique**: Perform the calibration with a blank calibration solution (4.5) and 3 to 5 equidistant calibration solutions (4.4) for an appropriate concentration range.

To correct for the instrumental drift calibration should be performed every 10 samples (if possible the option of reslope using the middle standard point should be applied every 5 samples)

Calibration solutions can be prepared by the auto sampler from the highest standard solution, the minimum volume uptake should not be less than 4µl.

The blank calibration solution should be free of analyte, or below a well-documented maximum allowed calibration blank value (i.e. validation, control charts..).

It should be stressed that the linearity of the calibration curve is often limited. The calibration curve is automatically plot by instrument software, if linear regression is set checked that $r \leq 0.995$ or switch to second order equation.

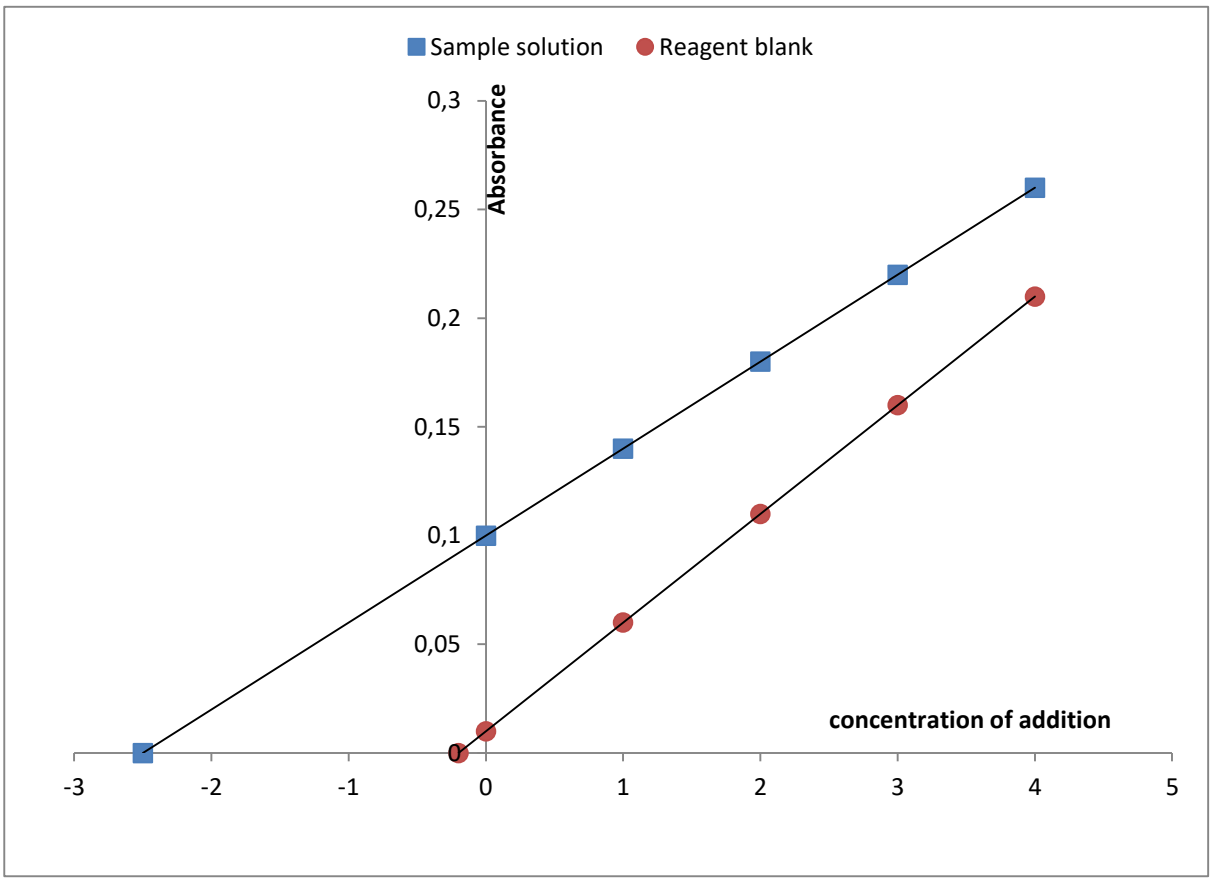
8.4.2. **Standard addition method**: This technique involves preparing same aliquots of sample solution with increasing amount of analyte. As describe in section 7 for the spike experiment using an increasing concentration of standard (V1 and V2 should stay the same). The auto sampler can be programed to perform standard addition. Determine the analyte concentration in the reagent blank solution the same way. Example of standard addition is given in figure 1. The concentration is obtained by dividing the absorbance of zero addition by the slope.

The standard addition should be performed for each type of matrix (i.e. a sediment sample solution cannot be measured with a standard addition curve done on a fish sample solution). For similar sample matrices (i.e. same fish species) the slope obtained with one sample can be used for other measurements respecting recalibration every 10samples.

For standard addition to be valid the following limitation should be taken into consideration:

- The resulting calibration should be linear ($r \leq 0.995$), software calibration equation is a linear regression
- The additions should represent ideally 50, 100, 150 and 200% of the sample concentration
- The standard addition technic cannot be used to correct for spectral interferences, such as unspecific background absorption, and should not be used if interferences change the signal by a factor of more than three.

Figure 1 Standard addition example



8.5. Measure sample blank and sample solutions (prepared following section 3) record the concentration as calculated by the software and calculate results following equation 3 (section 9), if samples exceed the highest point of calibration dilute appropriately. As an option a smaller volume of solution can be injected to stay under linear range of the instrument.

8.6. Quality control solutions: Quality control solutions as described below should be measured during the run. An example of a sequence order with recommended criteria and action is given in table 4.

Table 4 Example of analytical sequence:

Solutions Description	Performance	Action
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1 -4	r>0.995	recalibrate in the linearity range
ICV	±10% of true value	Stop until resolve
Sample blank	< maximum allowed blank value	
CRM	Fall in certificate value within coverage uncertainty, or fall within acceptable criteria of the QC chart	Stop until resolve, check Matrix spike and run again with standard addition method if necessary
Matrix Spike	recovery 100% ± 15%	switch to standard addition, keep record for future analyses of the same matrix
Dilution Test	sample 1 = 5x sample 1 diluted 5x within 10%	switch to standard addition, keep record for future analyses of the same matrix
Unknown Sample 1-10	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute

ETC…(restart sequence from calibration blank)

8.6.1. **Initial Calibration Verification ICV**:

After the initial calibration, the calibration curve must be verified using the initial calibration verification (ICV) standard.

The ICV standard is a standard solution made from an independent (second source) material at or near midrange. This solution as calibration standard is prepared using the same type of acid or combination of acids and at the same concentration as will result in the test portion.

The acceptance criteria for the ICV standard must be ±10% of its true value

If the calibration curve cannot be verified within the specified limits, the cause must be determined and the instrument recalibrated before samples are analyzed. The analysis data for the ICV must be kept on file with the sample analysis

The calibration curve must also be verified at the end of each analysis batch and/or after every 10 samples. If the calibration cannot be verified within the specified limits, the sample analysis must be discontinued, the cause determined and the instrument recalibrated. All samples following the last acceptable test must be reanalyzed.

8.6.2. **Blank solution** (4.5): Maximum allowed blank concentration should be well documented and if blank solution exceeds this value all samples prepared along the contaminated blank should be prepared again and re analyzed.

8.6.3. **Post digestion spike**

Each unknown type of sample should be spike to check for potential matrix effect.

This spike is consider as a single point standard addition, and should be performed with a minimum dilution factor. Recovery of spike calculated as equation 1 should be 85-115%. If this test failed it is recommended to run analyses with standard addition method. (see section 7 for detail)

8.6.4. **Dilution test**:

If the analyte concentration is sufficiently high (minimally, a factor of 10 above the lower limit of quantitation after dilution), an analysis of a 1:5 dilution should agree within ±10% of the original determination. If not, then a chemical or physical interference effect should be suspected, and method of standard addition is recommended.

8.6.5. **Certified reference material**:

At least one certified reference material of a representative matrix will be prepared with each batch of sample, the calculated result should be comparable with the value of the certificate within the coverage uncertainty.(Linsinger, 2010), to show evidence of unbias result.

Results of CRM should be record for quality control purpose and plot in control chart (UNEP/IOC/IAEA 1994)

9. CALCULATION OF RESULTS:

Results are calculated with equation 3

Equation 3: $w(m) = \frac{(\rho 1 - \rho 0)}{\mathrm{m}} \times f \times V \times R$

w(m) mass fraction of element m in the sample in mg kg^{-1}
ρ1: concentration of element m in milligrams per liter as measured in the sample solution
ρ0: concentration of element m in milligrams per liter as measured in the blank solution
f: is the dilution factor calculated as

$$f = \frac{final\ volume}{initial\ volume}$$

or equal to 1 if ρ1 is determined in undiluted solution
R: recovery calculated using CRM (see 8.6.5) or pre digestion spike

10. EXPRESSION OF RESULTS:

The rounding of values will depend of the uncertainty reported with the result. Uncertainty component should be reported with all results. (ISO 1995, Nordtest 2004)

Example : w(Pb) = 8.5 ± 1.2 mg kg^{1}

METHOD 6020B

INDUCTIVELY COUPLED PLASMA—MASS SPECTROMETRY

METHOD 6020B

INDUCTIVELY COUPLED PLASMA—MASS SPECTROMETRY

SW-846 is not intended to be an analytical training manual. Therefore, method procedures are written based on the assumption that they will be performed by analysts who are formally trained in at least the basic principles of chemical analysis and in the use of the subject technology.

In addition, SW-846 methods, with the exception of required method use for the analysis of method-defined parameters, are intended to be guidance methods which contain general information on how to perform an analytical procedure or technique which a laboratory can use as a basic starting point for generating its own detailed standard operating procedure (SOP), either for its own general use or for a specific project application. The performance data included in this method are for guidance purposes only, and are not intended to be and must not be used as absolute quality control (QC) acceptance criteria for purposes of laboratory accreditation.

1.0 SCOPE AND APPLICATION

1.1 Inductively coupled plasma-mass spectrometry (ICP-MS) is applicable to the determination of sub-µg/L concentrations of a large number of elements in water samples and in waste extracts or digests (Refs. 1 and 2). When dissolved constituents are required, samples must be filtered and acid-preserved prior to analysis. No digestion is required prior to analysis for dissolved elements in water samples. Acid digestion prior to filtration and analysis is required for groundwater, aqueous samples, industrial wastes, soils, sludges, sediments, and other solid wastes for which total (acid-leachable) elements are required. The analyst should insure that a sample digestion method is chosen that is appropriate for each analyte and the intended use of the data. Refer to Chapter Three for the appropriate digestion procedures.

1.2 ICP-MS has been applied to the determination of over 60 elements in various matrices. Analytes for which the acceptability of Method 6020 has been demonstrated through multi-laboratory testing on solid and aqueous wastes are listed below.

Element	Symbol	CASRN[a]	Element	Symbol	CASRN[a]
Aluminum	Al	7429-90-5	Magnesium	Mg	7439-95-4
Antimony	Sb	7440-36-0	Manganese	Mn	7439-96-5
Arsenic	As	7440-38-2	Mercury	Hg	7439-97-6
Barium	Ba	7440-39-3	Nickel	Ni	7440-02-0
Beryllium	Be	7440-41-7	Potassium	K	7440-09-7

Element	Symbol	CASRN[a]	Element	Symbol	CASRN[a]
Cadmium	Cd	7440-43-9	Selenium	Se	7782-49-2
Calcium	Ca	7440-70-2	Silver	Ag	7440-22-4
Chromium	Cr	7440-47-3	Sodium	Na	7440-23-5
Cobalt	Co	7440-48-4	Thallium	Tl	7440-28-0
Copper	Cu	7440-50-8	Vanadium	V	7440-62-2
Iron	Fe	7439-89-6	Zinc	Zn	7440-66-6
Lead	Pb	7439-92-1			

[a]Chemical Abstract Service Registry Number

The performance acceptability of ICP-MS for the determination of the listed elements was based upon comparison of the multi-laboratory testing results with those obtained from either furnace atomic absorption spectrophotometry or inductively coupled plasma—optical emission spectrometry. It should be noted that one multi-laboratory study was conducted in 1988. As advances in ICP-MS instrumentation and software have been made since that time, other elements have been added through validation and with additional improvements in performance of the method. Performance, in general, presently exceeds the original multi-laboratory performance data for the listed elements (and others) that are provided in Sec. 13.0. Instrument detection limits (IDLs), lower limits of quantitation (LLOQs) and linear ranges will vary with the matrices, instrumentation, and operating conditions. In relatively simple matrices, IDLs will generally be < 0.1 µg/L. For less sensitive elements (e.g., Se and As) and desensitized major elements, IDLs may be ≥ 1.0 µg/L.

1.3 If Method 6020 is used to determine any analyte not listed in Sec. 1.2, it is the responsibility of the analyst to demonstrate the precision and bias of the method for the waste to be analyzed. The analyst must always monitor potential sources of interferences and take appropriate action to ensure data of known quality (see Sec. 9.0). Other elements and matrices may be analyzed by this method if performance is demonstrated for the analyte of interest, in the matrices of interest, at the concentration levels of interest in the same manner as the listed elements and matrices (see Sec. 9.0).

1.4 Use of this method should be restricted to spectroscopists who are knowledgeable in the recognition and correction of spectral, chemical, and physical interferences in ICP-MS analysis.

1.5 An appropriate internal standard is necessary for each analyte determined by ICP-MS. Recommended internal standards are ^{6}Li, ^{45}Sc, ^{89}Y, ^{103}Rh, ^{115}In, ^{159}Tb, ^{165}Ho, and ^{209}Bi. The lithium internal standard should have an enriched abundance of ^{6}Li, so that

interference from lithium native to the sample is minimized. Other elements may need to be used as internal standards when samples contain significant native amounts of the recommended internal standards as indicated by high bias of internal standard recoveries.

Note: Other potential causes of a high bias should also be considered before a final decision is made that the internal standard high bias is caused by an excessive concentration of the internal standard isotope in the sample.

1.6 Prior to employing this method, analysts are advised to consult the preparatory method for each type of procedure that may be employed in the overall analysis (e.g., Methods 3005, 3010, 3015, 3031, 3040, 3050, 3051, 3052, 7000, and 6800) for additional information on QC procedures, development of QC acceptance criteria, calculations, and general guidance. Analysts also should consult the disclaimer statement at the front of the manual and the information in Chapter Two for guidance on the intended flexibility in the choice of methods, apparatus, materials, reagents, and supplies, and on the responsibilities of the analyst for demonstrating that the techniques employed are appropriate for the analytes of interest, in the matrix of interest, and at the levels of concern.

In addition, analysts and data users are advised that, except where explicitly specified in a regulation, the use of SW-846 methods is *not* mandatory in response to Federal testing requirements. The information contained in this method is provided by EPA as guidance to be used by the analyst and the regulated community in making judgments necessary to generate results that meet the data quality objectives (DQOs) for the intended application.

1.7 This method is restricted to use by, or under supervision of, properly experienced and trained personnel. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 Prior to analysis, aqueous and solid samples are solubilized or digested using the appropriate sample preparation methods (see Chapter Three). When analyzing groundwater samples for dissolved constituents, acid digestion is not necessary, if the samples are filtered and acid-preserved prior to analysis (e.g., Methods 3005, 3010, 3015, 3031, 3050, 3051 and 3052). For oils, greases, or waxes, use the solvent dissolution procedure in method 3040 to prepare the samples.

2.2 This method describes multi-element determinations using ICP-MS in environmental samples. The method measures ions produced by a radio-frequency inductively coupled plasma. Analyte species in liquid are nebulized and the resulting aerosol is transported by argon gas into the plasma torch. The ions produced by high temperatures are entrained in the plasma gas and introduced, by means of an interface, into a mass spectrometer. The ions produced in the plasma are sorted according to their mass-to-charge (*m/z*) ratios and quantified with a channel electron multiplier. Interferences must be assessed and valid corrections applied or the data flagged to indicate problems. Interference correction must include compensation for background ions contributed by the plasma gas, reagents, and constituents of the sample matrix.

3.0 DEFINITIONS

Refer to Chapter One, Chapter Three, and the manufacturer's instructions for definitions that may be relevant to this procedure.

4.0 INTERFERENCES

4.1 Isobaric elemental interferences in ICP-MS are caused by isotopes of different elements forming atomic ions with the same nominal *m/z* ratio. A data system must be used to correct for these interferences. This involves determining the signal for another isotope of the interfering element and subtracting the appropriate signal from the analyte isotope signal.

4.2 Isobaric molecular and doubly charged ion interferences in ICP-MS are caused by ions consisting of more than one atom or charge, respectively. Most isobaric interferences that could affect ICP-MS determinations have been identified in the literature (Refs. 3 and 4). Examples include $^{75}ArCl^+$ ion on the ^{75}As signal and MoO^+ ions on the cadmium isotopes. While the approach used to correct for molecular isobaric interferences is demonstrated below using the natural isotope abundances from the literature (Ref. 5), the most precise coefficients for an instrument can be determined from the ratio of the net isotope signals *observed* for a standard solution of the interfering element at a concentration which produces sufficient interference at the isotopes of interest that a reliable measurement can be made. Because the ^{35}Cl natural abundance of 75.77% is 3.13 times the ^{37}Cl abundance of 24.23%, the chloride correction for arsenic can be calculated (approximately) as follows (where the $^{38}Ar^{37}Cl^+$ contribution at *m/z* 75 is a negligible 0.06% of the $^{40}Ar^{35}Cl^+$ signal):

Corrected arsenic signal (using the abundances of natural isotopes for coefficient approximations) =

(*m/z* 75 signal) - (3.13) [(*m/z* 77 signal) - (0.87) (*m/z* 82 signal)]

where, the final term adjusts for any selenium contribution at 77 *m/z*,

NOTE: Arsenic values can be biased high by this type of equation when the net signal at *m/z* 82 is caused by ions other than $^{82}Se^+$, (e.g., $^{81}BrH^+$ from bromine wastes [Ref. 6]).

NOTE: The coefficients should be verified experimentally using the procedures or coefficients provided by the instrument manufacturer.

Similarly,

Corrected cadmium signal (using the abundances of natural isotopes for coefficient approximations) =

(*m/z* 114 signal) - (0.027)(*m/z* 118 signal) - (1.63)(*m/z* 108 signal)

where, the last 2 terms adjust for any $^{114}Sn^{+}$ or $^{114}MoO^{+}$ contributions at *m/z* 114.

NOTE: Cadmium values will be biased low by this type of equation when $^{92}ZrO^{+}$ ions contribute at *m/z* 108, but use of *m/z* 111 for Cd is even subject to direct ($^{94}ZrOH^{+}$) and indirect ($^{90}ZrO^{+}$) additive interferences when Zr is present.

NOTE: With respect to the arsenic equation above, the coefficients could be improved. For example, the coefficient to modify "3.13" (in the equation above) for a particular instrument can be determined from the observed ratio of the m/z 75 to the m/z 77 net isotope signals for a solution of hydrochloric acid. The concentration of HCl used should provide enough signal at the measured isotopes to ensure that a reliable measurement can be made, while not exceeding the linear range of the detector.

The accuracy of these types of equations is based upon the constancy of the *observed* isotopic ratios for the interfering species. Corrections that presume a constant fraction of a molecular ion relative to the "parent" ion have not been found (Ref. 7) to be reliable, e.g., oxide levels can vary with operating conditions. If a correction for an oxide ion is based upon the ratio of parent-to-oxide ion intensities, the correction must be adjusted for the degree of oxide formation by the use of an appropriate oxide internal standard previously demonstrated to form a similar level of oxide as the interferent. For example, this type of correction has been reported (Ref. 7) for oxide-ion corrections using ThO^{+}/Th^{+} for the determination of rare earth elements. The use of aerosol desolvation and/or mixed gas plasmas have been shown to greatly reduce molecular interferences (Ref. 8). These techniques can be used, provided that IDL, bias, and precision specifications for analysis of the samples can be met.

4.3 As technology continues to develop, modifications to existing ICP-MS instrumentation can reduce or completely remove common interferences thus eliminating the need for reliance on correction equations. Instruments must be able to demonstrate successful freedom from interferences. Examples of such modifications are discussed in more detail below:

4.3.1 Recent ICP-MS instruments may include collision or reaction cells for removal of molecular isobaric interferences. This type of interference removal is effective, and highly recommended for complex and/or varying matrices. The systems work either by collision of molecular species with an inert gas (usually helium) or by reaction of molecular species or the target analyte with reactive gases (e.g., ammonia or methane). Manufacturer recommendations should be followed for the configuration of the collision/reaction cell. This technique may eliminate the need for most correction equations, but freedom from interference still needs to be demonstrated using the spectral interference check (SIC) solutions described in sections 7.23 and 9.9.

4.3.2 High resolution ICP-MS instruments are available based on several mass analyzer designs with much higher mass resolution within the mass range of traditional ICP-MS instruments. These mass analyzers are not based on quadrupole mass analyzers and have orders of magnitude resolution above quadrupoles, which helps reduce or eliminate interference from polyatomic ions with the same nominal mass. These mass analyzers reduce or eliminate the need for most correction equations, but the instrument needs to be operated at sufficient resolution to remove the expected

interference. For example, resolving ^{52}Cr from $^{40}Ar^{12}C$ requires a resolution of around 4000, while resolving ^{75}As from $^{40}Ar^{35}Cl$ requires a resolution of around 8000. Freedom from interferences needs to be demonstrated for the particular higher resolution mass analyzers ICP-MS.

4.4 Additionally, solid-phase chelation may be used to eliminate isobaric interferences from both element and molecular sources. An on-line method has been demonstrated for environmental waters such as sea water, drinking water and acid decomposed samples. Acid decomposed samples refer to samples decomposed by methods similar to methods 3052, 3051, 3050 or 3015. Samples with% levels of iron and aluminum should be avoided. The method also provides a method for preconcentration to enhance detection limits simultaneously with elimination of isobaric interferences. The method relies on chelating resins such as imminodiacetate or other appropriate resins and selectively concentrates the elements of interest while eliminating interfering elements from the sample matrix. By eliminating the elements that are direct isobaric interferences or those that form isobaric interfering molecular masses, the mass region is simplified and these interferences cannot occur. The method has been proven effective for the certification of reference materials and validated using reference materials (Refs. 13-15). The method has the potential to be used on-line or off-line as an effective sample preparation method specifically designed to address interference problems.

4.5 Since commercial quadrupole ICP-MS instruments nominally provide unit resolution at 10% of the peak height, very high ion currents at adjacent masses can also contribute to ion signals at the mass of interest. Although this type of interference is uncommon, it is not easily corrected, and samples exhibiting a significant problem of this type could need resolution improvement, matrix separation, or analysis using another verified and documented isotope, or otherwise the use of another method.

4.6 Physical interferences are associated with the sample nebulization and transport processes as well as with ion-transmission efficiencies. Nebulization and transport processes can be affected if a matrix component causes a change in surface tension or viscosity. Changes in matrix composition can cause significant signal suppression or enhancement (Ref. 9). Dissolved solids can deposit on the nebulizer tip of a pneumatic nebulizer and on the interface skimmers (reducing the orifice size and the instrument performance). Dissolved solid levels below 0.2% (2,000 mg/L) have been currently recommended (Ref. 10) to minimize solid deposition, although currently-available ICP-MS systems may be able to tolerate much higher levels. An internal standard can be used to correct for physical interferences, if it is carefully matched to the analyte so that the two elements are similarly affected by matrix changes (Ref. 11). When intolerable physical interferences are present in a sample, a significant suppression of the internal standard signals (to less than 30% of the signals in the calibrations standard) will be observed. Dilution of the sample five-fold (i.e., dilute one part sample with four parts diluent [1:5 = 1+4]) will usually eliminate the problem.

4.7 Memory interferences or carry-over can occur when there are large concentration differences between samples or standards which are analyzed sequentially. Sample deposition on the sampler and skimmer cones, spray chamber design, and the type of nebulizer affect the extent of the memory interferences which are observed. The rinse period between samples must be long enough to eliminate significant memory interference.

4.8 Reagents and sample processing hardware may yield artifacts and/or interferences to sample analysis. All of these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks. Specific selection of reagents may be necessary. Refer to each method to be used for specific guidance on QC procedures.

5.0 SAFETY

5.1 This method does not address all safety issues associated with its use. The laboratory is responsible for maintaining a safe work environment and a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this method. A reference file of material safety data sheets (MSDSs) should be available to all personnel involved in these analyses.

5.2 Concentrated nitric and hydrochloric acids are moderately toxic and extremely irritating to skin and mucus membranes. Use these reagents in a hood and if eye or skin contact occurs, flush with large volumes of water. Always wear safety glasses or a shield for eye protection when working with these reagents.

5.3 **Hydrofluoric acid is a very toxic acid and penetrates the skin and tissues deeply if not treated immediately.** Injury occurs in two stages: firstly, by hydration that induces tissue necrosis; and secondly, by penetration of fluoride ions deep into the tissue and thereby reacting with calcium. Boric acid and/or other complexing reagents and appropriate treatment agents should be administered immediately.

WARNING: Consult appropriate safety literature for determining the proper protective eyewear, clothing and gloves to use when handling hydrofluoric acid. **Always have appropriate treatment materials readily available prior to working with this acid.** See Method 3052 for additional recommendations for handling hydrofluoric acid from a safety and an instrument standpoint.

5.4 Many metal salts, are extremely toxic if inhaled or swallowed.

WARNING: Exercise extreme care to ensure that samples and standards are handled safely and properly and that all exhaust gases are properly vented. Wash hands thoroughly after handling.

6.0 EQUIPMENT AND SUPPLIES

6.1 Inductively coupled plasma-mass spectrometer:

6.1.1 The system must be capable of providing resolution, better than or equal to 1.0 u (unified atomic mass unit) at 10% peak height. The system must have a mass range from at least 6 to 240 u and a data system that allows corrections for isobaric interferences and the application of the internal standard technique. Use of a mass-flow controller for the nebulizer argon and a peristaltic pump for the sample solution are recommended.

6.1.2 Argon gas, high-purity grade (99.99%).

6.2 Volumetric flasks of suitable material composition, precision and accuracy

6.3 Volumetric pipets of suitable material composition, precision and accuracy

This section does not list all common laboratory ware (e.g., beakers) that might be used.

7.0 REAGENTS AND STANDARDS

7.1 Reagent-grade, and whenever necessary, ultra-high purity-grade chemicals, must be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

7.2 Reagent water - Reagent water must be interference free. All references to water in this method refer to reagent water unless otherwise specified.

7.3 Ultra high-purity or equivalent acids must be used in the preparation of standards and for sample processing. Redistilled acids are recommended because of the high sensitivity of ICP-MS. Nitric acid at less than 2% (v/v) is necessary for ICP-MS to minimize damage to the interface and to minimize isobaric molecular-ion interferences with the analytes. Many more molecular-ion interferences are observed when hydrochloric and sulfuric acids are used (Refs. 3 and 4). The use of 1% (v/v) HCl is necessary for the stability of antimony and silver concentrations in the range of 50 - 500 µg/L. For concentrations greater than 500 µg/L silver, additional HCl will be needed. As a consequence, the accuracy of analytes that need significant chloride molecular-ion corrections (e.g., As and V) will degrade.

7.3.1 Nitric acid (concentrated), HNO_3

7.3.2 Nitric acid (50% [v/v]), HNO_3 - Prepare by adding 500 mL concentrated HNO_3 to 400 mL water and diluting to 1 L.

7.3.3 Nitric acid (1% [v/v]), HNO_3 - Prepare by adding 10 mL concentrated HNO_3 to 400 mL water and diluting to 1 L.

7.3.4 Hydrochloric acid (concentrated), HCl

7.3.5 Hydrochloric acid (37%), HCl - Prepare by adding 370 mL concentrated HCl to 400 mL water and diluting to 1L.

7.3.6 Hydrofluoric acid (concentrated), HF

7.3.7 Phosphoric acid (concentrated), H_3PO_4

7.3.8 Phosphoric acid (85% [v/v]), H_3PO_4 - Prepare by adding 850 mL concentrated H_3PO_4 to 100 mL water and diluting to 1 L.

7.3.9 Sulfuric acid (concentrated), H_2SO_4

7.3.10 Sulfuric acid (96% [v/v]) H_2SO_4, - Prepare by adding 40 mL water to a 2 L glass beaker. While gently stirring, carefully add 960 mL concentrated H_2SO_4 to the beaker. Mix until combined. Allow to cool. Carefully, quantitatively transfer solution to a 1-L volumetric flask. Bring to volume with additional water if necessary. Mix thoroughly through inversion to combine.

WARNING: Considerable heat is generated upon combining sulfuric acid and water. The use of appropriate personal protection (e.g. proper gloves, safety glasses and protective clothing) is necessary to avoid personal injury such as thermal burns or acid burns due to solution splatter. Also, always add acid to water (rather than water to acid) to reduce splatter.

7.3.11 Citric acid, $HO_2CCH_2C(OH)(CO_2H)CH_2CO_2H$

7.4 Bismuth(III) oxide, Bi_2O_3

7.5 Holmium(III) carbonate pentahydrate, $Ho_2(CO_3)_3 \cdot 5H_2O$

7.6 Indium (powder), In

7.7 Lithium[^{6}Li] carbonate (95 atom % ^{6}Li), $^6Li_2CO_3$

7.8 Ammonium hexachlororhodate(III), $(NH_4)_3RhCl_6$

7.9 Scandium(III) oxide, Sc_2O_3

7.10 Terbium(III) carbonate pentahydrate, $Tb_2(CO_3)_3 \cdot 5H_2O$

7.11 Yttrium(III) carbonate, $Y_2(CO_3)_3 \cdot 3H_2O$

7.12 Ammonium hexafluorotitanate(IV), $(NH_4)_2TiF_6$

7.13 Ammonium molybdate(VI) $(NH_4)_2MoO_4$

7.14 Aluminum(III) nitrate nonahydrate, $Al(NO_3)_3 \cdot 9H_2O$

7.15 Calcium carbonate, $CaCO_3$

7.16 Iron powder, Fe

7.17 Magnesium oxide, MgO

7.18 Sodium carbonate, Na_2CO_3

7.19 Potassium carbonate, K_2CO_3

7.20 Standard stock solutions - Purchase standard stock solutions from an appropriate commercial source. Otherwise, prepare them manually in the laboratory using only ultra, high-purity grade chemicals or metals (≥ 99.99% purity). See Method 6010 for instructions on preparing standard solutions from solids. Replace stock standards when succeeding dilutions for the preparation of calibration standards cannot be verified.

7.20.1 Bismuth internal standard stock solution (100 µg/mL Bi) - Dissolve 0.1115 g Bi_2O_3 in a minimum amount of dilute HNO_3. Add 10 mL concentrated HNO_3 and dilute to 1 L with reagent water.

7.20.2 Holmium internal standard stock solution (100 µg/mL Ho) - Dissolve 0.1757 g $Ho_2(CO_3)_3 \cdot 5H_2O$ in 10 mL reagent water and 10 mL concentrated HNO_3. After dissolution is complete, warm the solution to degas. Add 10 mL concentrated HNO_3 and dilute to 1 L with reagent water.

7.20.3 Indium internal standard stock solution (100 µg/mL In) - Dissolve 0.1000 g indium in 10 mL concentrated HNO_3. Dilute to 1 L with reagent water.

7.20.4 Lithium internal standard stock solution (100 µg/mL ^6Li) - Dissolve 0.6312 g $^6Li_2CO_3$ (95% atomic abundance) in 10 mL of reagent water and 10 mL concentrated HNO_3. After dissolution is complete, warm the solution to degas. Add 10 mL concentrated HNO_3 and dilute to 1 L with reagent water.

7.20.5 Rhodium internal standard stock solution (100 µg/mL Rh) - Dissolve 0.3593 g $(NH_4)_3RhCl_6$ in 10 mL reagent water. Add 100 mL concentrated HCl and dilute to 1 L with reagent water.

7.20.6 Scandium internal standard stock solution (100 µg/mL Sc) - Dissolve 0.15343 g Sc_2O_3 in 10 mL 50% hot HNO_3. Add 5 mL concentrated HNO_3 and dilute to 1 L with reagent water.

7.20.7 Terbium internal standard stock solution (100 µg/mL Tb) - Dissolve 0.1828 g $Tb_2(CO_3)_3 \cdot 5H_2O$ in 10 mL 50% HNO_3. After dissolution is complete, warm the solution to degas. Add 5 mL concentrated HNO_3 and dilute to 1 L with reagent water.

7.20.8 Yttrium internal standard stock solution (100 µg/mL Y) - Dissolve 0.2316 g $Y_2(CO_3)_3 \cdot 3H_2O$ in 10 mL 50% HNO_3. Add 5 mL concentrated HNO_3 and dilute to 1 L with reagent water.

7.20.9 Titanium interference stock solution (100 µg/mL Ti) - Dissolve 0.4133 g $(NH_4)_2TiF_6$ in reagent water. Add 2 drops concentrated HF and dilute to 1 L with reagent water.

7.20.10 Molybdenum interference stock solution (100 µg/mL Mo) - Dissolve 0.2043 g $(NH_4)_2MoO_4$ in reagent water. Dilute to 1 L with reagent water.

7.20.11 Gold preservative stock solution for mercury (100 µg/mL Au) - Purchase as a commercially prepared, high-purity solution of $AuCl_3$ in dilute HCl matrix.

7.21 Mixed-calibration standard solutions - Prepare by diluting stock standard solutions to levels in the linear range for the instrument, using the same combination and concentrations of acids used in the preparation of the sample digestates (approximately 1% HNO_3). The calibration standard solutions must contain a suitable concentration of an appropriate internal standard for each analyte. Internal standards may be added on-line at the time of analysis using a second channel of the peristaltic pump and an appropriate mixing manifold. Generally, an internal standard should be no more than 50 u removed from the analyte. Recommended internal standards include ^{6}Li, ^{45}Sc, ^{89}Y, ^{103}Rh, ^{115}In, ^{159}Tb, ^{169}Ho, and ^{209}Bi. Prior to preparing the mixed standards, each stock standard solution must be analyzed separately to determine possible spectral interferences or the presence of impurities.

NOTE: Care should be taken when preparing the calibration standards to ensure that the elements are compatible and stable when mixed together. Standards which interfere with another analyte, or which are contaminated with another analyte, may not be included in the same calibration standard as that analyte.

Transfer the mixed-standard solutions to an appropriate container for storage. Freshly mixed standards must be prepared as needed with the realization that concentrations can change upon aging. Calibration standards must be initially verified using a QC standard (see Sec. 7.24).

7.22 Blanks - Three types of blanks are necessary for analysis: (1) the calibration blank, which is used in establishing the calibration curve; (2) the method blank, which is used to monitor for possible contamination resulting from the sample preparation procedure; and (3) the rinse blank, which is used to flush the system between all samples and standards.

7.22.1 Calibration blank - Prepare by acidifying reagent water using the same combination and concentrations of acids used in the preparation of the matrix-matched calibration standards (Sec. 7.21) along with the selected concentrations of internal standards, such that there is an appropriate internal standard element for each of the target analytes. The use of HCl for antimony and silver is discussed in Sec. 7.3. The calibration blank will also be used for all initial calibration blank (ICB) and continuing calibration blank (CCB) determinations.

7.22.2 Method blank — Prepare by a processing either a volume of reagent water equal to that used for actual aqueous samples, or, otherwise, a clean, empty container, equivalent to that used for actual solid samples through all of the preparatory and instrument determination steps used for making ICP-MS determinations in samples. These steps may include, but are not limited to, pre-filtering, digestion, dilution, filtering, and analysis (refer to Sec. 9.5).

7.22.3 Rinse blank - Prepare as a 1 - 2% HNO_3 solution. Prepare a sufficient quantity such that it may be used to flush the system in between standards and samples. If mercury is to be analyzed, the rinse blank should also contain 2 µg/mL $AuCl_3$.

7.23 Spectral interference check (SIC) solutions - Prepare so as to contain known concentrations of interfering elements that will demonstrate the appropriate magnitude of interferences and provide an adequate test of any corrections. Chloride in the SIC solution provides a means to evaluate software corrections for chloride-related interferences such as $^{35}Cl^{16}O^{+}$ on $^{51}V^{+}$ and $^{40}Ar^{35}Cl^{+}$ on $^{75}As^{+}$. Iron is used to demonstrate adequate resolution of the spectrometer for the determination of manganese. Molybdenum serves to indicate oxide effects on cadmium isotopes. The other components are present to evaluate the ability of the measurement system to correct for various molecular-ion isobaric interferences. The SIC is used to verify that the interference levels are corrected by the data system within appropriate QC limits.

NOTE: The final SIC solution concentrations in Table 1 are intended to evaluate corrections for known interferences on only the analytes identified in Sec. 1.0. If the test method is to be used to determine other element(s), it is the responsibility of the analyst to modify the SIC solution accordingly, or prepare an alternative SIC solution, so as to allow adequate verification of interference corrections on the additional element(s) (see Sec. 9.9).

7.23.1 Mixed stock SIC solutions - Prepare the SIC stock solutions using only ultra-pure reagents. They can be obtained commercially or prepared using the following procedures:

7.23.1.1 Mixed SIC stock solution I - Prepare by adding 13.903 g $Al(NO_3)_3 \cdot 9H_2O$, 2.498 g $CaCO_3$ (previously dried at 180 EC for 1 hr), 1.000 g Fe, 1.658 g MgO, 2.305 g Na_2CO_3 and 1.767 g K_2CO_3 to 25 mL of reagent water. Slowly add 40 mL of (50%) HNO_3. After dissolution is complete, warm the solution to degas. Cool and dilute to 1 L with reagent water.

7.23.1.2 Mixed SIC stock solution II - Prepare by slowly adding 7.444 g 85% H_3PO_4, 6.373 g 96% H_2SO_4, 40.024 g 37% HCl, and 10.664 g citric acid ($C_6O_7H_8$) to 100 mL of reagent water. Dilute to 1 L with reagent water.

7.23.2 Mixed working SIC solution - Prepare by combining 10.0 mL of SIC stock solution I, 2.0 mL each of 100-µg/mL titanium stock solution and 100-µg/mL molybdenum stock solution, and 5.0 mL of SIC stock solution II. Dilute to 100 mL with reagent water. Prepare fresh weekly.

7.24 Initial calibration verification (ICV) standard - Prepare by combining compatible metals from standard stock solution sources that differ from those used for the preparation of the calibration standards. The ICV should be prepared so as to contain metal concentrations that are near, but not equal to, the midpoint concentration level of the calibration curve.

7.25 Continuing calibration verification (CCV) standard - Prepare using the same acid matrix and stock standards employed when preparing the calibration standards. The CCV should be prepared so as to contain metal concentrations equal or nearly equivalent to the midpoint concentration of the calibration curve.

7.26 Mass spectrometer tuning solution - Prepare so as to contain elements that represent all of the mass regions of interest (i.e., 10 µg/L Li, Co, In, and Tl) in order to verify that

the resolution and mass calibration of the instrument are within the designated specifications (see Sec. 10.1).

7.27 If the determination of one or more metals using a non-aqueous solvent is required, then all standards and quality control samples must be prepared on a weight/weight basis in the non-aqueous solvent since the density of non-aqueous solvents is not uniform. Standards and quality control materials containing organometallic materials that are soluble in non-aqueous solvents are available from a variety of vendors.

8.0 SAMPLE COLLECTION, PRESERVATION, AND STORAGE

Sample collection, preservation and storage requirements may vary by EPA program and may be specified in a regulation or project planning document that requires compliance monitoring for a given contaminant. Where such requirements are specified in the regulation, follow those requirements. In the absence of specific regulatory requirements, use the following information as guidance in determining the sample collection, preservation and storage requirements.

See Chapter Three, Inorganic Analytes, for sample collection and preservation instructions.

9.0 QUALITY CONTROL

9.1 Refer to Chapter One for guidance on quality assurance (QA) and QC protocols. When inconsistencies exist between QC guidelines, method-specific QC criteria take precedence over those criteria given in Chapter One. Any effort involving the collection of analytical data should include development of a structured and systematic planning document, such as a Quality Assurance Project Plan (QAPP) or a Sampling and Analysis Plan (SAP), which translates project objectives and specifications into directions for those that will implement the project and assess the results. Each laboratory should maintain a formal quality assurance program. The laboratory should also maintain records to document the quality of the data generated. All data sheets and QC data should be maintained for reference or inspection.

9.2 Refer to Methods 3005, 3010, 3015, 3031, 3040, 3050, 3051, 3052, 7000, and 6800 for QC procedures to ensure the proper operation of the various sample preparation techniques. Any more specific QC procedures provided in this method will supersede those noted in Methods 3005, 3010, 3015, 3031, 3040, 3050, 3051, 3052, 7000, and 6800.

9.3 Instrument Detection Limits

Instrument detection limits (IDLs) are useful means to evaluate the instrument noise level and response changes over time for each analyte from a series of reagent blank analyses to obtain a calculated concentration. They are not to be confused with the lower limit of quantitation, nor should they be used in establishing this limit. It may be helpful to compare the calculated IDLs to the established lower limit of quantitation, however, it should be understood that the lower limit of quantitation needs to be verified according to the guidance in Sec. 9.8. IDLs in µg/L can be estimated as the mean of the blank result plus three times the standard

deviation of 10 replicate analyses of the reagent blank solution. (Use zero for the mean if the mean is negative). Each measurement should be performed as though it were a separate analytical sample (i.e., each measurement must be followed by a rinse and/or any other procedure normally performed between the analysis of separate samples). IDLs should be determined at least once using new equipment, after major instrument maintenance such as changing the detector, and/or at a frequency designated by the project. An instrument log book should be kept with the dates and information pertaining to each IDL performed.

9.4 Initial demonstration of proficiency

Each laboratory must demonstrate initial proficiency with each sample preparation and determinative method combination by generating data of acceptable precision and bias for target analytes in a clean matrix. If an autosampler is used to perform sample dilutions, before using the autosampler to dilute samples, the laboratory should satisfy itself that those dilutions are of equivalent or better accuracy than is achieved by an experienced analyst performing manual dilutions. It is recommended that the laboratory should repeat the demonstration of proficiency whenever new staff members are trained or significant changes in instrumentation are made.

9.5 Initially, before processing any samples, the analyst should demonstrate that all parts of the equipment that come into direct contact with the sample and reagents are interference-free. This is accomplished through the analysis of a method blank. As a continuing check, each time samples are digested and analyzed, and when there is a change in reagents, a method blank should be prepared and analyzed for the compounds of interest as a safeguard against chronic laboratory contamination. If an interference is observed that would prevent the determination of the target analyte, determine the source and eliminate it, if possible, before processing the samples. The method blank should be carried through all stages of sample preparation and instrument determination procedures. When new reagents or chemicals are received, the laboratory should monitor the preparation and/or analysis blanks associated with samples for any signs of contamination. It is not necessary to test every new batch of reagents or chemicals prior to sample preparation if the source shows no prior problems. However, if reagents are changed during a preparation batch, separate blanks need to be prepared for each set of reagents.

9.6 Linear range

The linear range establishes the highest concentration that may be reported without diluting the sample. Following calibration, the laboratory may choose to analyze a standard at a higher concentration than the high standard in the calibration. The standard must recover within 10% of the true value, and if successful, establishes the linear range. The linear range standards must be analyzed in the same instrument run as the calibration they are associated with (i.e., on a daily basis) but may be analyzed anywhere within that run. If a linear range standard is not analyzed for any specific element, the highest standard in the calibration becomes the linear range.

9.7 Sample QC for preparation and analysis

The laboratory must also have procedures for documenting the effect of the matrix on method performance (precision, bias, and sensitivity). At a minimum, this should include the

analysis of QC samples including a method blank, a matrix spike (MS), a laboratory control sample (LCS), and a duplicate sample in each analytical batch. Any method blanks, LCS, MS samples, and duplicate samples should be subjected to the same preparatory and instrument determination procedures as those used on actual samples (see Sec. 11.0).

9.7.1 For each batch of samples analyzed, at least one method blank must be carried throughout the entire sample preparation and instrument determination process, as described in Chapter One. The importance of the method blank is to aid in identifying when and/or if sample contamination is occurring. The method blank is considered to be acceptable if it does not contain the target analytes at concentration levels that exceed the acceptance limits defined in Chapter One or in the project-specific DQOs. The laboratory should not subtract the results of the method blank from those of any associated samples. Such "blank subtraction" is not reliable because it is based on a single method blank value rather than a statistically determined blank concentration.

Blanks are generally considered to be acceptable if target analyte concentrations are less than ½ the LLOQ or are less than project-specific requirements. Blanks may contain analyte concentrations greater than acceptance limits if the associated samples in the batch are unaffected (i.e. targets are not present in samples or sample concentrations **are ≥10X** the blank). Other criteria may be used depending on the needs of the project.

If the method blank fails to meet the necessary acceptance criteria, it should be re-analyzed once. If still unacceptable, then all samples associated with the method blank must be re-prepared and re-analyzed, along with all other appropriate analysis batch QC samples. If the method blank results do not meet the acceptance criteria and reanalysis is not practical, then the laboratory should report the sample results along with the method blank results, and provide a discussion of the potential impact of the contamination on the sample results. However, if an analyte of interest is found in a sample in the batch near its concentration confirmed in the blank, the presence and/or concentration of that analyte should be considered suspect and may require qualification. Refer to Chapter One for additional guidance regarding the proper protocol when analyzing method blanks.

9.7.2 Documenting the effect of the matrix should include the analysis of at least one MS and one duplicate unspiked sample or one matrix spike/matrix spike duplicate (MS/MSD) pair for each batch of samples processed, at a minimum frequency of one per every 20 samples, as described in Chapter One. An MS/MSD pair is used to document the bias and precision of a method in a given sample matrix. The decision on whether to prepare and analyze duplicate samples or an MS/MSD pair must be based on knowledge of the samples in the analysis batch. If samples are expected to contain target analytes above the LLOQ, laboratories may choose to use an MS and a duplicate analysis of an unspiked field sample. If samples are not expected to contain target analytes above the LLOQ, the laboratories should use an MS/MSD pair.

MS/MSD samples should be spiked with each target element at the project-specific action levels, or, when lacking project-specific action levels, between the low- and mid-level standards, as appropriate. Acceptance criteria should be set at laboratory-derived limits, developed through the use of historical analyses, for each matrix type being analyzed. However, historically derived acceptance limits must not exceed ± 25%

recovery of the target element spike values for bias, and ≤ 20 relative percent difference (RPD) for precision. In the absence of historical data, MS/MSD acceptance limits should be set at ± 25% recovery and ≤ 20 RPD. Refer to Sec. 4.0 of Chapter One for further guidance. If the bias and precision indicators in an analytical batch fail to meet the acceptance criteria, then the interference test discussed in Sec. 9.10 should be performed. Refer to the definitions of bias and precision, in Chapter One, for the proper data reduction protocols.

NOTE: If the background sample concentration is very low or non-detect, a spike of greater than 5 times the background concentration is still acceptable. To assess data precision with duplicate analyses, it is preferable to use a high concentration field sample to prepare unspiked laboratory duplicates for metals analyses.

Calculate the RPD between duplicate or MS determinations as follows:

$$RPD = \frac{|D_1 - D_2|}{\left(\frac{|D_1 + D_2|}{2}\right)} \times 100$$

where:

RPD = relative percent difference
D_1 = MS or first sample analysis value
D_2 = MSD or duplicate sample analysis value

9.7.3 At least one LCS should be prepared and analyzed with each batch of analytical samples processed, at a minimum frequency of one LCS per every 20 samples, as described in Chapter One. The LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS should be spiked at the same levels and using the same spiking materials as the corresponding MS/MSD (see above Sec. 9.7.2). When the results of the MS analysis indicate a potential problem due to the sample matrix itself, the LCS results are used to verify that the laboratory can acceptably perform the analysis in a clean matrix.

LCS acceptance criteria should be set at laboratory-derived limits, developed through the use of historical analyses. However, historically derived acceptance limits must not exceed ± 20% of the target element spike values. In the absence of historical data, LCS acceptance limits should be set at ± 20%. If the result of an LCS does not meet the established acceptance criteria, it should be re-analyzed once. If still unacceptable, then all samples associated with the LCS must be re-prepared and re-analyzed, along with all other appropriate analysis batch QC samples.

9.7.4 Reference materials containing known amounts of target elements are recommended when an appropriately similar medium of interest are available as one type of QC after appropriate sample preparation. The reference material may be used as the LCS. For soil reference materials, the manufacturers' established acceptance criterion should be used. For solid reference materials, ± 20% (see Sec. 9.7.3) recovery of the reported manufacturers' target element values may not be achievable. Refer to Chapters One and Three for additional information.

9.8 Lower Limit of Quantitation (LLOQ) check standard

9.8.1 The laboratory should establish the LLOQ as the lowest point of quantitation which, in most cases, is the lowest concentration in the calibration curve. The LLOQ is initially verified by the analysis of at least 7 replicate samples, spiked at the LLOQ and processed through all preparation and analysis steps of the method. The mean recovery and relative standard deviation of these samples provide an initial statement of precision and accuracy at the LLOQ. In most cases the mean recovery should be +/- 35% of the true value and RSD should be $\leq$ 20%. In-house limits may be calculated when sufficient data points exist. Monitoring recovery of LLOQ over time is useful for assessing precision and bias. Refer to a scientifically valid and published method such as Chapter 9 of Quality Assurance of Chemical Measurements (Taylor 1987) or the Report of the Federal Advisory Committee on Detection and Quantitation Approaches and Uses in Clean Water Act Programs (http://water.epa.gov/scitech/methods/cwa/det/index.cfm) for calculating precision and bias for LLOQ.

9.8.2 Ongoing LLOQ verification, at a minimum, is on a quarterly basis to validate quantitation capability at low analyte concentration levels. This verification may be accomplished either with clean control material (e.g., reagent water, method blanks, Ottawa sand, diatomaceous earth, etc.) or a representative sample matrix (free of target compounds). Optimally, the LLOQ should be less than the desired regulatory action levels based on the stated project-specific requirements.

9.9 Verify the magnitude of elemental and molecular-ion isobaric interferences and the adequacy of any corrections at the beginning of an analytical run or once every 12 hours of continuing sample analysis, whichever is more frequent. Do this by analyzing the SIC solution. Results for the unspiked elements in the SIC solution should be less than 2 times the LLOQ. Note that it may not be possible to obtain SIC spiking solutions that are completely free of the unspiked elements. If the presence and concentration of an unspiked element can be confirmed via vendor documentation and/or determination of multiple isotopes of the element in the correct ratios, the concentration actually present may be subtracted from the determined value prior to comparing to the LLOQ limits. Refer to Sec. 4.0 for a discussion on interferences and potential solutions to those interferences if additional guidance is needed.

9.10 The intensities of each internal standard must be monitored for every analysis to ensure that it does not decrease below 30%, with respect to its intensity during the initial calibration. If this occurs, a significant matrix effect must be suspected. Under these conditions, the IDL has degraded, and therefore the correction capability of the internal-standardization technique must then be questioned. If this happens, perform the following procedure:

9.10.1 Make sure the instrument has not drifted by observing the internal standard intensities in the nearest clean matrix, i.e., the calibration blank. If the low internal standard intensities are also observed in the nearby calibration blank, terminate the analysis, correct the problem, recalibrate the instrument, verify the new calibration, and reanalyze the affected samples.

9.10.2 If drift has not been demonstrated to occur as outlined in Sec. 9.10.1, matrix effects need to be removed by diluting the affected sample. Dilute the sample five-

fold (1:5), taking into consideration the need to add the appropriate amounts of internal standards, and reanalyze. If the first dilution does not eliminate the problem, repeat the dilution procedure in an iterative fashion, using ever-increasing dilutions, until the internal-standard intensities exceed the 30% acceptance limit. Correct the reported results using the appropriate dilution factors.

9.11 To obtain analyte data of known quality, it is necessary to measure more than the analytes of interest in order to apply corrections or to determine whether interference corrections are necessary. For example, tungsten oxide molecular-ion species can be very difficult to distinguish from mercury isotopes. If the concentrations of interference sources (such as C, Cl, Mo, Zr, W) are such that, at the correction factor, the analyte is less than the LLOQ and the concentration of interferents are insignificant, then the data may go uncorrected.

NOTE: Monitoring the interference sources does not inevitably necessitate monitoring of the interferant itself, but that a molecular species may be monitored to indicate the presence of the interferent.

When correction equations are used, all QC criteria must also be met. Extensive QC for interference corrections is needed at all times. The monitored masses must include those elements whose hydrogen, oxygen, hydroxyl, chlorine, nitrogen, carbon and sulfur molecular ions could impact the analytes of interest. Unsuspected interferences may be detected by adding pure major matrix components to a sample to observe any impact on the analyte signals. When an interference source is present, the sample elements impacted must be flagged to indicate (a) the percentage interference correction applied to the data; or (b) an uncorrected interference, by virtue of the elemental equation used for quantitation. The isotope proportions for an element or molecular-ion cluster provide information useful for QA.

NOTE: Only isobaric elemental, molecular, and doubly charged interference corrections, which employ the observed isotopic-response ratios or parent-to-oxide ratios (provided an oxide internal standard is used as described in Sec. 4.2) for each instrument system, are acceptable corrections for use in this method.

9.12 It is recommended that the laboratory adopt additional QA practices for use with this method. The specific practices that are most productive depend upon the needs of the laboratory and the nature of the samples. Whenever possible, the laboratory should analyze reference materials and participate in relevant performance evaluation (PE) studies.

9.13 If less than acceptable bias and precision data are generated for the matrix spike(s), the additional QC protocols in Sections 9.13.1 and/or 9.13.2 should be performed prior to reporting concentration data for the elements in this method. At a minimum these tests should be performed with each batch of samples prepared/analyzed with corresponding unacceptable data quality results. If matrix interference effects are confirmed, then an alternative test method should be considered or the current test method modified, so that the analysis is not affected by the same interference. The use of a standard-addition analysis procedure may also be used to compensate for this effect (refer to Method 7000).

9.13.1 Dilution test

If the analyte concentration is within the linear range of the instrument and sufficiently high (minimally, a factor of 25 times greater than the LLOQ), an analysis of a 1:5 dilution should agree to within ± 20% of the original determination. If not, then a chemical or physical interference effect must be suspected. The matrix spike is often a good choice of sample for the dilution test, since reasonable concentrations of most analytes are present. Elements that fail the dilution test are reported as estimated values.

9.13.2 Post-digestion MS

If a high concentration sample is not available for performing the dilution test, then a post-digestion MS should be performed. The test only needs to be performed for the specific elements that failed original matrix spike limits, and only if the spike concentration added was greater than the concentration determined in the unspiked sample. Following preparation, which may include, but is not limited to, pre-filtration, digestion, dilution and filtration, an aliquot, or dilution thereof, should be obtained from the final aqueous, unspiked-analytical sample, and spiked with a known quantity of target elements. The spike addition should be based on the indigenous concentration of each element of interest in the sample. The recovery of the post-digestion MS should fall within a ± 25 % acceptance range, relative to the known true value, or otherwise within the laboratory-derived acceptance limits. If the post-digestion MS recovery fails to meet the acceptance criteria, the sample results must be reported as estimated values.

9.14 Ultra-trace analysis necessitates the use of clean chemistry practices. Several suggestions for the reduction of contaminants in the analytical blank are provided in Chapter Three, Inorganic Analytes.

10.0 CALIBRATION AND STANDARDIZATION

10.1 Conduct mass calibration and resolution verification checks in the mass regions of interest using the mass spectrometer tuning solution (Sec. 7.26). The mass calibration and resolution verification acceptance criteria must be met prior to the analysis of samples. If the mass calibration differs by more than 0.1 u from the true value, then the mass calibration must be adjusted to the correct value. The resolution must also be verified to be less than 0.9 u full width at 10% peak height.

10.2 At a minimum, the elements required for the project plus any required for interference correction must be calibrated. Recommended isotopes for the analytes in Sec. 1.2 are provided in Table 2. Flush the system in between each standard and sample using the rinse blank (Sec. 7.22.3). The rinse time needs to be sufficient to ensure that analytes present in the linear range are effectively cleaned out prior to analysis of the subsequent sample. Use the average of at least three readings (of a single injection) for both calibration standard and sample analyses.

10.3 Calibration standards should be prepared on an as-needed basis unless stability warrants preparing fresh daily, (or each time a batch of samples is analyzed). If the ICV standard is prepared daily and the results of the ICV analyses meet the acceptance criteria,

then the calibration standards do not need to be prepared daily and may be prepared and stored for as long as the calibration standard viability can be verified through the use of the ICV. If the ICV fails to meet the acceptance criteria, trouble shoot the situation, and then prepare a new set of calibration standards if needed and recalibrate the instrument

10.4 A calibration curve must be analyzed daily. The instrument may be calibrated using a single point standard and a calibration blank (ICB) or a multipoint calibration curve. If a multipoint curve is used a minimum of three standards are required and the correlation coefficient (r) should be $\geq$ 0.995 or the coefficient of determination (r^2) should be $\geq$ 0.990. Relative Standard Error may be used as an alternative to r or r^2, and should be $\leq$ 20%. If a multipoint calibration is used the low standard must be at or below the LLOQ.

NOTE: Inversely weighted linear regressions or other methods may be used in order to minimize curve fitting errors at the low end of the calibration curve.

10.5 After the initial calibration is completed it is verified using several checks.

10.5.1 Initial Calibration Verification (ICV) - The ICV is a standard prepared from a different source than the initial calibration standards. It is analyzed at approximately the mid-level of the calibration and serves as a check that the initial calibration standards are at the correct concentrations. The acceptance range is 90-110% of the true value.

10.5.2 Low-level readback or verification - For a multi-point calibration, the low level standard should quantitate to within 80-120% of the true value. For a single point calibration, a standard from the same source as the calibration standard and at or below the LLOQ is analyzed and should recover within 80-120% of the true value.

10.5.3 Mid-level readback or verification - For a multi-point calibration, the mid-level standard should quantitate to within 90-110% of the true value. For a single point calibration, a standard from the same source as the calibration standard and at the mid-point of the linear range is analyzed and should recover within 90-110% of the true value.

10.5.4 Initial Calibration blank (ICB) - If a multi-level calibration is used, an ICB is analyzed immediately after the calibration (or after the ICV) and must not contain target analytes above half the LLOQ. If a single point calibration is used, the calibration is forced through the ICB, but a second ICB is analyzed as a check and must not contain target analytes above half the LLOQ. If the ICB consistently has target analyte concentrations greater than half the LLOQ, the LLOQ should be re-evaluated.

NOTE: After cleaning the sampler and skimmer cones, improved performance in calibration stability has been observed by method users if the instrument is exposed to the SIC solution. Improved performance has also been observed if the instrument is allowed to rinse for 5 - 10 minutes before starting the calibration process.

10.5.5 Verify the ongoing validity of the calibration curve after every 10 samples, and at the end of each analysis batch run, through the analysis of a CCV standard (Sec. 7.25) and a CCB (Sec. 7.22.1). For the curve to be considered valid the analysis result of the CCV standard must be within ± 10% of its true value and the CCB must not contain target analytes above the LLOQ. If the calibration cannot be verified, sample analysis

must be discontinued, the cause of the problem determined and the instrument recalibrated. All samples following the last acceptable CCV standard must be reanalyzed Flow-injection systems may be used as long as they can meet the performance criteria of the method.

11.0 PROCEDURE

11.1 Preliminary treatment of most samples is necessary because of the complexity and variability of sample matrices. Groundwater samples which have been pre-filtered and acidified will not need acid digestion. Samples which are not digested must either use an internal standard or be matrix-matched with the standards (i.e., acid concentrations should match). Solubilization and digestion procedures are presented in Chapter Three, Inorganic Analytes.

NOTE: If mercury is to be analyzed, the digestion procedure must use mixed nitric and hydrochloric acids through all steps of the digestion. Mercury will be lost if the sample is digested when hydrochloric acid is not present. If it has not already been added to the sample as a preservative, Au should be added to give a final concentration of 2 mg/L (use 2.0 mL of gold preservative stock (Sec. 7.20.11) per 100 mL of sample) to preserve the mercury and to prevent it from plating out in the sample introduction system.

11.2 Initiate an appropriate operating configuration of the instrument computer according to the instrument manufacturer's instructions.

11.3 Set up the instrument with the proper operating parameters according to the instrument manufacturer's instructions.

11.4 Operating conditions

Tune the instrument by following the instructions provided by the instrument manufacturer. Allow at least 30 minutes for the instrument to equilibrate before analyzing samples.

NOTE: The instrument should have features that protect it from high ion currents. If not, precautions must be taken to protect the detector. A channel electron multiplier or active film multiplier will suffer from fatigue after being exposed to high ion currents. This fatigue can last from several seconds to hours depending on the extent of exposure. During this time period, response factors are constantly changing, which invalidates the calibration curve, causes instability, and invalidates sample analyses.

11.5 Calibrate the instrument following the procedure outlined in Sec. 10.0.

11.6 Flush the system with the rinse blank solution (Sec. 7.22.3) until the signal levels return to the data quality objectives or method LLOQs (usually about 30 seconds) before the analysis of each sample. Nebulize each sample until a steady-state signal is achieved (usually about 30 seconds) prior to collecting data.

11.7 Dilute and reanalyze samples that exceed the linear range for an analyte (or species needed for a correction) or measure an alternate, but less-abundant, isotope. The

linearity at the alternate mass must be confirmed by appropriate calibration (see Sec. 10.4). Alternatively apply solid-phase chelation chromatography to eliminate the matrix as described in Sec. 4.3.

11.8 Determination of percent dry weight

When sample results are to be calculated on a dry-weight basis, a separate portion of sample for this determination should be weighed out at the same time as the portion used for analytical determination.

CAUTION: The drying oven should be contained in a hood or vented. Significant laboratory contamination may result from a heavily contaminated hazardous waste sample.

11.8.1 Immediately after weighing the sample aliquot to be digested, weigh an additional 5- to 10-g aliquot of the sample to the nearest 0.01g into a tared crucible. Dry this aliquot overnight at 105 EC. Allow the sample to cool in a desiccator before weighing.

11.8.2 Calculate the % dry weight as follows:

$$\%\,\text{dry weight} = \frac{\text{g of dry sample}}{\text{g of sample}} \times 100$$

This oven-dried aliquot is not used for the extraction and should be appropriately disposed of once the dry weight is determined.

12.0 DATA ANALYSIS AND CALCULATIONS

12.1 If dilutions were performed, apply the appropriate corrections to the sample values.

12.2 If appropriate, or required by the project or regulation for data reporting, calculate results for solids on a dry-weight basis as follows:

$$Concentration_{DW} = \frac{C \times V}{W \times S}$$

where:

$Concentration_{DW}$ = Concentration on a dry weight basis (mg/kg)
C = Digest concentration (mg/L)
V = Final volume after sample preparation (L)
W =Wet sample mass (kg)
S = % Solids/100 = % dry weight/100

Calculations must include appropriate interference corrections (see Sec. 4.2 for examples), internal-standard normalization, and the summation of signals at 206, 207, and 208 *m/z* for lead (to compensate for any differences in the abundances of these isotopes between samples and standards).

13.0 METHOD PERFORMANCE

Performance data and related information are provided in SW-846 methods only as examples and guidance. The data do not represent required performance criteria for users of the methods. Instead, performance criteria should be developed on a project-specific basis, and the laboratory should establish in-house QC performance criteria for the application of this method. These performance data are not intended to be and must not be used as absolute QC acceptance criteria for purposes of laboratory accreditation.

Table 3 summarizes the method performance data for aqueous and sea water samples with interfering elements removed and samples preconcentrated prior to analysis. Table 4 summarizes the performance data for a simulated drinking water standard. These data are provided for guidance purposes only.

14.0 POLLUTION PREVENTION

14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity and/or toxicity of waste at the point of generation. Numerous opportunities for pollution prevention exist in laboratory operations. The EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option.

14.2 For information about pollution prevention that may be applicable to laboratories and research institutions consult *Less is Better: Laboratory Chemical Management for Waste Reduction*, a free publication available from the American Chemical Society (ACS), Committee on Chemical Safety, http://portal.acs.org/portal/fileFetch/C/WPCP_012290/pdf/WPCP_012290.pdf.

15.0 WASTE MANAGEMENT

The Environmental Protection Agency requires that laboratory waste management practices be conducted consistent with all applicable rules and regulations. The Agency urges laboratories to protect the air, water, and land by minimizing and controlling all releases from hoods and bench operations, complying with the letter and spirit of any sewer discharge permits and regulations, and by complying with all solid and hazardous waste regulations, particularly the hazardous waste identification rules and land disposal restrictions. For further information on waste management, consult the ACS publication listed in Sec. 14.2.

TABLE 2

RECOMMENDED ELEMENTAL ISOTOPES FOR SELECTED ELEMENTS

Element of Interest	Mass of Isotope
Aluminum	**27**
Antimony	121, **123**
Arsenic	**75**
Barium	138, 137, 136, **135**, 134
Beryllium	**9**
Bismuth (IS)	209
Cadmium	**114**, 112, **111**, 110, 113, 116, 106
Calcium (I)	42, 43, **44**, 46, 48
Chlorine (I)	35, 37, (77, 82)[a]
Chromium	**52**, **53**, **50**, 54
Cobalt	**59**
Copper	**63**, **65**
Holmium (IS)	165
Indium (IS)	**115**, 113
Iron (I)	**56**, **54**, **57**, 58
Lanthanum (I)	139
Lead	**208**, **207**, **206**, 204
Lithium (IS)	6[b], 7
Magnesium (I)	24, **25**, **26**
Manganese	**55**
Mercury	202, **200**, 199, 201
Molybdenum (I)	98, 95, 96, 92, **97**, 94, (108)[a]
Nickel	58, **60**, 62, **61**, 64
Potassium (I)	**39**
Rhodium (IS)	103
Scandium (IS)	45
Selenium	80, **78**, **82**, **76**, **77**, 74
Silver	**107**, **109**
Sodium (I)	**23**
Terbium (IS)	159
Thallium	**205**, 203
Vanadium	**51**, **50**
Tin (I)	120, **118**
Yttrium (IS)	89
Zinc	64, **66**, **68**, **67**, 70

NOTE: Method 6020 is recommended for only those analytes listed in Sec.1.2. Other elements are included in this table because they are potential interferents (labeled I) in the determination of recommended analytes, or because they are commonly used internal standards (labeled IS). Isotopes are listed in descending order of natural abundance. The most generally useful isotopes are underlined and in boldface, although certain matrices may necessitate the use of alternative isotopes.

[a] These masses are also useful for interference correction (Sec. 4.2).

[b] Internal standard must be enriched in the ^{6}Li isotope. This minimizes interference from indigenous lithium.

TABLE 3

METHOD PERFORMANCE DATA FOR AQUEOUS AND SEA WATER SAMPLES [a]
WITH INTERFERING ELEMENTS REMOVED AND SAMPLES PRECONCENTRATED PRIOR TO ANALYSIS

ELEMENT	ISOTOPE	CONCENTRATION (ng/mL) [b]		
		9.0 mL	27.0 mL	CERTIFIED
Manganese	55	1.8±0.05	1.9±0.2	1.99±0.15

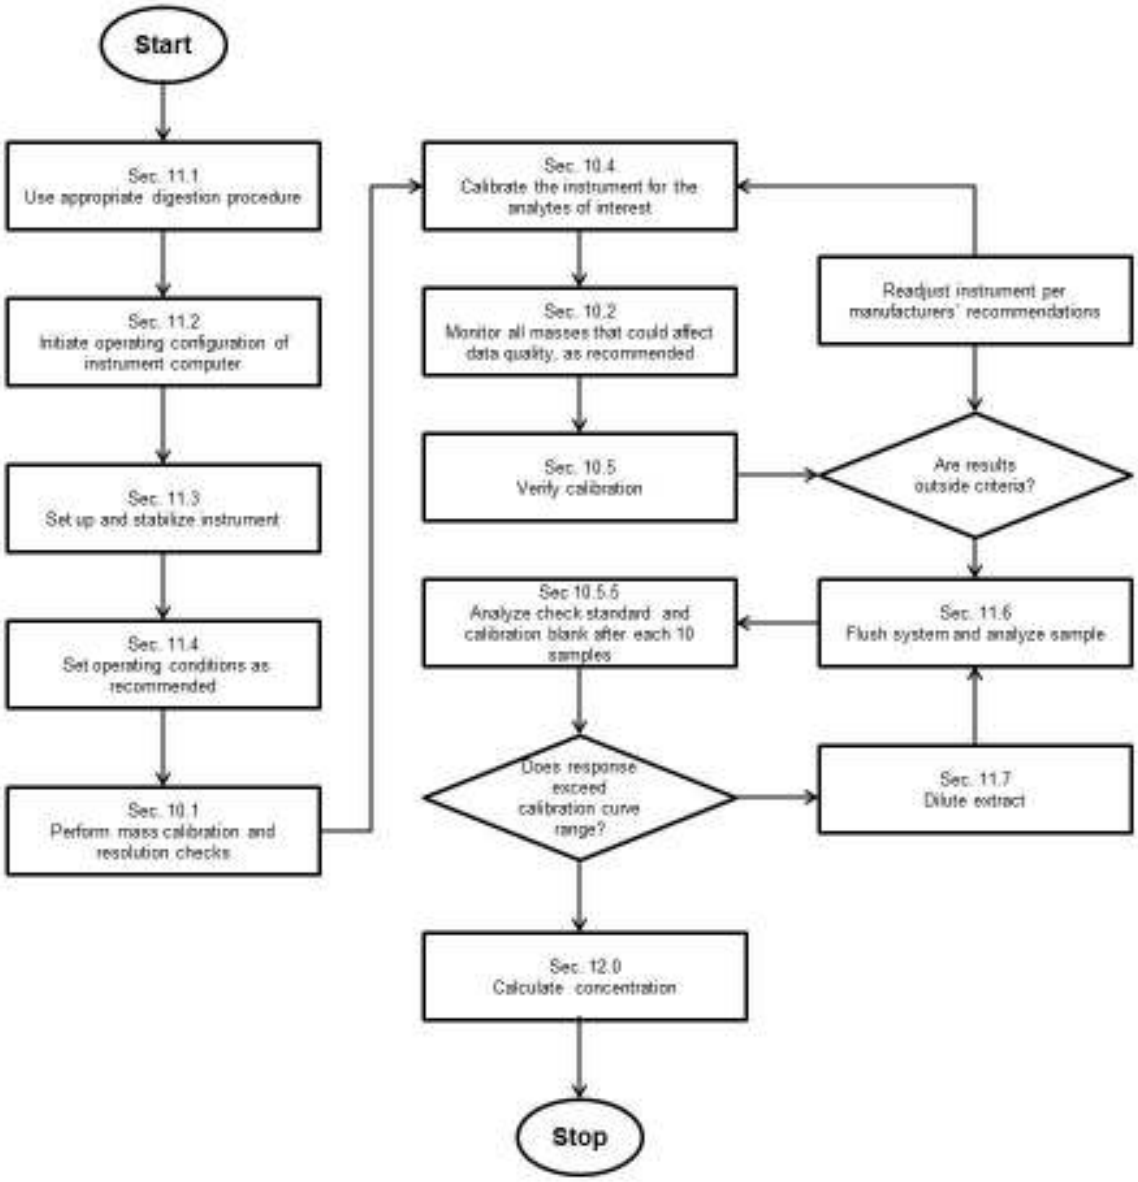
METHOD 6020A

INDUCTIVELY COUPLED PLASMA - MASS SPECTROMETRY



Appendix A

Summary of Revisions to Method 6020 (From Revision 1, February 2007):

1. Improved overall method formatting for consistency with new SW-846 methods style guidance.
2. Section 1.2 – Changed “Inductively coupled plasma—atomic emission spectrometry” to “Inductively coupled plasma—optical emission spectrometry”.
3. Section 1.6 - inserted references to additional 3000 series preparatory methods to ICP analysis. Also added method 6800 to sections 1.6 and 9.2 as a preparatory method.
4. Inserted additional safety guidance regarding the use of HF.
5. Inserted new section (7.27) regarding analysis of non-aqueous solvents.
6. Reformatted certain paragraphs with the heading "NOTE" or "WARNING" to better denote the importance of the recommendations provided therein.
7. Extensively reformatted “REAGENTS AND STANDARDS” section and to meet current SW-846 method guidelines.
8. Significantly updated and expanded “QUALITY CONTROL” section for better adherence to current SW-846 method guidelines and for improved alignment with current universal practices for published analytical methods.
9. Inserted new sections (Sections 7.23 and 9.9) to describe the preparation and use of the spectral interference check (SIC) solution; also added instructions to match the matrix of this solution to that of the calibration standards.
10. Renamed "QC standard" as "ICV standard" in Sec. 7.24.
11. Added new Sec. 7.25 describing the preparation of a "CCV" standard, consistent with the equivalent section in 6010.
12. Replaced the term “unity” with “uniform” in Section 7.27.
13. Removed all references to method 7000 except for guidance regarding the method of standard addition.
14. The term “accuracy” was replaced by “bias” where appropriate.
15. In Section 9.4, the requirement to repeat the demonstration of proficiency for new staff and instrumentation changes was changed to a recommendation.
16. Section 9.7.2 – Added a note regarding MS/MSD spike concentrations and unspiked laboratory duplicates.
17. The section regarding analysis of reference materials (Sec. 9.7.4) was revised for clarity and the term “Standard Reference Material” was replaced with “reference material” throughout the method.
18. Inserted new section (Sec. 9.8) describing the preparation and use of an LLOQ standard. This section includes two new references for guidance on assessing precision and bias.
19. The section describing matrix interference check samples (Sec. 9.13) has been revised for clarity. The post-digestion MS is only recommended if a high concentration sample is not available for performing the dilution test.
20. Substituted certain terms with new terms (i.e. “must” in place of “shall”) to conform with the Performance-based Methods Approach goal of flexibility.
21. Removed reference to “linear dynamic range” as noted by the Inorganic Methods Work Group. Section 9.6 regarding the linear range was added.
22. Mid-level read back or verification standard added to Section 10.5.3.
23. Moved the sentence “If the ICB consistently has target analyte concentrations greater than half the LLOQ, the LLOQ should be re-evaluated.” From Section 10.5.5 to Section 10.5.4.
24. Added 95 as mass of isotope for molybdenum.

25. Tables 3 and 4 from 6020A presenting example precision and accuracy data for aqueous and solid matrices were removed.
26. Language was updated in Section 9.7.1 regarding method blanks.

Annex VI:

Recommended Method for the DETERMINATION OF TOTAL MERCURY IN MARINE SAMPLES BY THERMAL DECOMPOSITION AMALGAMATION AND ATOMIC ABSORPTION SPECTROPHOTOMETRY

REPORT

Recommended Method for the

DETERMINATION OF TOTAL MERCURY IN MARINE SAMPLES BY THERMAL DECOMPOSITION AMALGAMATION AND ATOMIC ABSORPTION SPECTROPHOTOMETRY

IAEA/NAEL

Marine Environmental Studies Laboratory in co-operation with

UNEP/MAP MED POL

December 2012

Recommended Method for the DETERMINATION OF TOTAL MERCURY IN MARINE SAMPLES BY THERMAL DECOMPOSITION AMALGAMATION AND ATOMIC ABSORPTION SPECTROPHOTOMETRY

TABLE OF CONTENTS

NOTE: This method is not intended to be an analytical training manual. Therefore, this method is written with the assumption that it will be performed by formally trained analytical chemist.

In addition, the IAEA recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method, they shall not be used as absolute QC acceptance criteria.

1. SCOPE

The method hereinafter describes the protocol for the determination of total mercury (inorganic and organic) in sediment and biological material.

By using this method, the total mercury in solid samples can be determined without sample chemical pre-treatment.

The recommended protocol is mainly based on the EPA 7473 method; users are encouraged to consult this document (EPA, 2007).

2. PRINCIPLE

The sample is dried and then chemically decomposed under oxygen in the decomposition furnace. The decomposition products are carried out to the catalytic section of the furnace, where oxidation is completed (halogens and nitrogen/sulfur oxides are trapped). The mercury present in the remaining decomposition products is selectively trapped on an amalgamator. After flushing the system with oxygen, the mercury vapour is released by rapid heating of the amalgamator, and carried through the absorbance cell in the light path of a single wavelength atomic absorption spectrophotometer. The absorbance is measured at 253.7 nm as a function of mercury quantity (ng).

The typical working range is 0.1–500 ng. The mercury vapour is carried through a long (first) and a short path length absorbance cell. The same quantity of mercury is measured twice with different sensitivity resulting in a dynamic range that spans four orders of magnitude.

The typical detection limit is 0.01 ng of mercury.

3. SAMPLE PRE-TREATMENT

The sediment samples are prepared following the recommendations of UNEP (2005);

The marine organisms are prepared following the recommendations of UNEP (1984, 1994).

4. REAGENTS

The reagents used shall meet the purity requirement of the subsequent analysis

4.1. ULTRAPUR WATER (type MilliQ)

4.2. NITRIC ACID 65%

4.3. POTASSIUM DICHROMATE OXIDIZING SOLUTION (10% w/v)

Weight 25 g of $K_2Cr_2O_7$ in 250 ml glass bottle, fill it up to 250 ml with water, and shake until total dissolution of solids. Keep the bottle tightly closed in a double plastic bag, and in an Hg free environment (i.e. laminar flow hood). This solution is stable indefinitely and rarely becomes contaminated.

4.4. COMMERCIAL STANDARD SOLUTION 1000 µg ml^{-1} MERCURY

Use a certified reference material solution; this solution should be accompanied by a certificate stipulating at minimum the traceability of the certified concentration, as well as the expiry date. The density of the solution, or the certified content in mg kg^{-1} should also be defined, to allow for the preparation of the calibration solution by weighing. Stock solutions should be kept at 5°C.

5. MATERIAL

5.1. SOLID MERCURY ANALYZER

Optionally equipped with an auto-sampler.

5.2. ANALYTICAL BALANCE

With a 0.001 g precision at least.

5.3. VOLUMETRIC CONTAINERS

Preferably in Teflon or glass.

5.4. PIPETTES

Some microliter pipettes sized ranging from 50 to 10000 µl are needed. The accuracy and precision of the pipettes used should be checked as a routine every 6 months, and the results obtained should be compared with the individual certificates.

5.5. METAL SPATULA (inox).

5.6. SAMPLE BOAT

Metal or metal alloy. Before measurement, sample boats are cleaned by heating over a flame until constant “red” to remove mercury.

5.7. OXYGEN

It should be of high purity and free of mercury. If there is a possible mercury contamination from oxygen, install a gold mesh filter between the cylinder and the instrument to prevent any mercury from entering the instrument.

6. CALIBRATION

6.1. PRIMARY CALIBRATION. This is the calibration of the instrument working range. This calibration is performed initially (usually done by the manufacturer and stored in the instrument), and/or when any significant instrumental parameters are changed (i.e. after maintenance).

6.2. PREPARE STANDARD SOLUTIONS of appropriate concentration by dilution of a commercial standard (see 4.4). It is recommended to prepare standard solution in Teflon or glass container, in 1 or 0.5% HNO_3 (see 4.2) and 0.1% (v/v) potassium dichromate (see 4.3). Fresh mercury standard should be prepared daily. Prepare a zero calibration solution using the same quantity of acid and potassium dichromate.

6.3. START THE INSTRUMENT according to the manufacturer recommendations.

6.4. CLEAN THE SYSTEM. Inject 100 µl of water and start the measurement with the recommended parameters (see 7.1). Repeat the cleaning until the absorbance is below 0.001ABS.

6.5. SET THE INSTRUMENT PARAMETERS (see 7.1) for selected volume (usually 100 µl) and inject the zero calibration, at least three measurements should be done. The zero solution serves to correct the amount of mercury in water and reagent used for preparing the calibration curve, hence the important of keeping the injected volume equal at all points of the calibration curve. If the amount of mercury in the zero calibration is high (i.e. more than 0.01 ng), it is recommended to check for contamination sources and to prepare new standard solution with clean acid.

6.6. STANDARDS ARE MEASURED from the lowest to the highest at least twice. The maximum relative standard deviation between readings should be 3% (except for zero calibration); if higher it is recommended to carry out more measurements.

6.7. EXAMPLE OF AMOUNTS used for recalibration (primary):

First Range:

Standard (ng ml^{-1})	1	3	10	30	100	300
Volume injected (µl)	100	100	100	100	100	100
Quantity of Hg (ng)	0.1	0.3	1	3	10	30

Second Range:

Standard (µg ml^{-1})	1	2	3	4	5	6
Volume injected (µl)	100	100	100	100	100	100
Quantity of Hg (ng)	100	200	300	400	500	600

Note: The calibration of the second range might induce problems for subsequent analysis, due to the relatively high quantity of mercury introduced (especially with memory effect). It should be performed only if there is a probability of using it (i.e. measuring samples with high mercury level > 1µg g^{-1}). After the reading of the last calibration point, clean the system (see 6.4).

6.8. ALTERNATIVE CALIBRATION CURVE can be performed using a solid certified reference material. In this case, weigh accurately a CRM onto a tare sample boat, set up the instrument according to the sample type (see 7.1) and measure the absorbance. The matrix of the CRM should be as similar as possible to the sample of interest. Repeat this procedure with different weights of the CRM and/or with different CRM, to get results in the desired working range.

6.9. CONSTRUCT A CALIBRATION CURVE by plotting the absorbance against Nano grams of mercury (this could be done automatically by the software). The type of equation will depend on the levels, as the response is not linear over the entire working range.

6.10. DAILY CALIBRATION: calibration performed every day with a minimum number of standards to ensure that the primary calibration is valid. It can be performed by using either liquid standard (see 6.2) or solid certified reference material (CRM) see 6.8. It should be performed in the range of interest, with at least two standards (or matrix CRM) and the results should agree within the acceptance criteria. The acceptance criteria should be set through the use of historical data, but the maximum deviation should not exceed 10%.

7. PROCEDURE

7.1. GENERAL ANALYTICAL PARAMETERS

The analytical parameters will depend on the sample size and matrix, and are instrument specific. It is important to follow the guidelines from the instrument manufacturer. There are three time to set: drying, decomposition and waiting.

Some typical recommended conditions below:

Drying time:

Sample type	Dry (s)	Comments
Liquid	0.7 x injected Volume (µl)	
Dry inorganic	10	
Organic liquid	50–300	To be optimized[1]
Dry organic (i.e. fat)	50–200	To be optimized[1]
Wet (i.e. fresh)	0.7 x weight x % moisture	Example: 100 mg with 45% moisture 0.7 x 100 x 0.45= 31.5s (35)

[1] In the case of organic, there is a risk of explosion especially with organic liquid; to optimize set the instrument at: 300s dry/ 150s decomposition/ 45s wait, do the measurement and check for possible small explosion, note the time of the phenomenon and add to the drying time 10s more.

Decomposition time:

Sample type	Decomposition (s)	Comments
Liquid	150–400	To be optimized[1]
Solid inorganic	120 + 0.4 x sample (mg)	To be optimized[1]
Solid organic	120	

[1] Set the instrument to XX (see above) dry/ 400s decomposition/ 45s wait, run a sample and observe the results. Decrease the decomposition time by 30s and repeat measurement. Continue until you observe a significant decrease, note that time and add to the decomposition time 30s more.

Waiting time:

It is recommended to use 40–45s, except for long decomposition time (over 200s) when it is beneficial to add 10s of waiting for every 100s of decomposition.

Note: These indications above are recommended by ALTECH (AMA 254).

7.2. ANALYSIS OF A SOLID SAMPLE

Weight a sample accurately onto a tare boat, insert the boat into the instrument, set the appropriate parameters (see 7.1) and start the measurements. The results can be records on absorbance, quantity or concentration depending on the instrument software. See 9: Calculation of results.

7.3. ANALYSIS OF BLANK FOR SOLID MEASUREMENT

Analyse an empty sample boat using the same instrument settings than for the sample.

7.4. ANALYSIS OF A LIQUID SAMPLE

Dose a known volume of the sample onto a sample boat, set the appropriate parameters (see 7.1) and start the measurements. The results can be records on absorbance, quantity or concentration depending on the instrument software. See the calculation section (see 9).

7.5. ANALYSIS OF BLANK FOR LIQUID

Repeat 7.4 with the same volume of blank solution (solution that contain the same reagent and chemical than the sample).

8. QUALITY CONTROL

8.1. For every day of analysis, the CALIBRATION SHOULD BE VALIDATED by doing a daily calibration (see 6.10) before starting the measurements. The results of the daily calibration should be recorded for quality control purposes.

8.2. CERTIFIED REFERENCE MATERIAL

At least one certified reference material of a representative matrix should be measured with each batch of the sample, the calculated results should fall in the value of the certificate and within the coverage uncertainty (Linsinger, 2010), to show evidence of unbiased results. The results for the CRM should be recorded for quality control purpose and plotted in a control chart (UNEP/IOC/IAEA 1994).

8.3. A DUPLICATE OR TRIPLICATE SAMPLE should be processed on a routine basis.

A duplicate sample should be processed with each analytical batch or for every 10 samples.

8.4. A SPIKED SAMPLE should also be included, whenever a new sample matrix is being analysed, especially if no certified reference material is available for that matrix. Measure a spiked sample by adding a known volume of standard solution (prepared as in paragraph 6.2) to the sample in the boat. Keep the spike volume small enough not to overspill. The recovery of spike calculated with the equation 2 should be 85–115% (this limits should be reset after collection of historical data). If the test fails, it is recommended to check the calibration (see 6.10) and/or to revise the instrument parameters (see 7.1).

$$\text{Spike (ng)} = \text{Concentration of standard (ng/ml)} \times \text{Volume of spike (ml)} \qquad \text{Equation 1}$$

$$\text{Recovery (\%)} = \frac{\text{Spiked sample (ng)} - \text{Unspiked sample (ng)}}{\text{Spike (ng)}} \times 100 \qquad \text{Equation 2}$$

To be valid the quantity of Spike (equation 1) should be in the range of 50–150% the quantity of unspiked sample.

9. CALCULATION OF RESULTS

9.1. SOLID SAMPLE RESULTS are calculated using equation 3

$$w(Hg) = \frac{(\rho 1 - \rho 0)}{\mathrm{m}} \times R \qquad \text{Equation 3}$$

Where:

w(Hg) is the mass fraction of element m in the sample, expressed in mg kg^{-1};

ρ1 is the quantity of mercury, expressed in ng as measured in the sample;

ρ0 is the quantity of mercury expressed in ng as measured in the blank (see 7.3);

R is the recovery calculated using the CRM (see 8.2) or spike (see 8.4);

m is the amount of sample in mg.

Note: ρ1 and ρ0 are calculated using calibration curve equation (usually done by software).

9.2. LIQUID SAMPLE RESULTS are calculated using equation 4

$$w(Hg) = \frac{\frac{(\rho 1 - \rho 0)}{Vi} \times V}{\mathrm{m}} \times f \times R \qquad \text{Equation 4}$$

Where:

w(Hg) is the mass fraction of mercury in the sample, expressed in mg kg^{-1};

ρ1 is the quantity of mercury, expressed in ng as measured in the sample solution;

ρ0 is the quantity of mercury expressed in ng as measured in the blank solution (see 7.4);

R is the recovery calculated using the CRM (see 8.2) or spike (see 8.4);

Vi is the injected volume (should be the same in sample and blank solution) in ml;

m is the amount of sample in mg;

V is the volume of solution in ml;

f is the dilution factor.

Note: ρ1 and ρ0 are calculated using calibration curve equation (usually done by software).

10. EXPRESSION OF RESULTS

The rounding of values will depend on the uncertainty reported with the results; in general for this method two or three significant figures should be reported.

The uncertainty component should be reported with all results. (ISO 2005, Nordtest 2004)

Example: w(Hg) = 0.512 ± 0.065 mg kg^{-1}.

RECOMMENDED METHOD ON THE DETERMINATION OF TOTAL MERCURY IN SAMPLES OF MARINE ORIGIN BY COLD VAPOUR ATOMIC ABSORPTION SPECTROMETRY

TABLE OF CONTENT

NOTE: This method is not intended to be an analytical training manual. Therefore, the method is written with the assumption that it will be used by formally trained analytical chemists.

In addition, the IAEA recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method they must not be used as absolute QC acceptance criteria.

1. SCOPE

This method describes a protocol for measurement of total mercury by cold vapour atomic absorption spectrometry (CV-AAS). The method is simple, rapid and applicable to a large number of environmental samples. This method is applicable when the element content in the digested solution is above the method limit (~ 0.15 ng ml^{-1} depending on instrument). The typical working range is 0.25–100 ng ml^{-1} for direct injection of cold vapour, using "batch system"; FIAS or amalgamation accessory will give better sensitivity.

2. PRINCIPLE

The sediment or biological samples are mineralized with strong acids. The inorganic mercury is reduced to its elemental form with stannous chloride. The cold mercury vapour is then passed through the quartz absorption cell of an atomic absorption spectrometer (AAS), where its concentration is measured. The light beam of Hg hallow cathode lamp is directed through the quartz cell, into a monochromator and onto a detector that measures the amount of light absorbed by the atomized vapour in the cell. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

3. REAGENT

The reagents used shall meet the purity requirement of the subsequent analysis:

3.1. WATER

Reagent water (referenced also as water in the text) should be free of contamination.

3.2. NITRIC ACID 65%

3.3. HYDROCHLORIC ACID (37%)

3.4. HYDROGEN PEROXIDE

3.5. VANADIUM PENTOXIDE (V_2O_5)

3.6. SILICON ANTI-FOAMING

3.7. HYDROXYLAMINE HYDROCHLORIDE ($NH_2OH.HCl$)

Dissolve 12.0 g of $NH_2OH.HCl$ in 100 ml reagent water. This solution may be purified by the addition of 0.1 ml of $SnCl_2$ solution and purging 1 hour with Hg-free argon.

3.8. POTASSIUM DICHROMATE OXIDIZING SOLUTION (10% w/v)

Weight 25 g of $K_2Cr_2O_7$ in a 250 ml glass bottle, fill it up to 250 ml with water, and shake until total dissolution of the solid. Keep the bottle tightly closed in a double plastic bag, and in an Hg free environment (i.e. laminar flow hood). This solution is stable indefinitely and rarely becomes contaminated.

3.9. BrCl OXIDIZING SOLUTION

Weigh accurately 11 g of KBrO3 and 15 g of KBr into a clean 1 liter glass bottle. Add 200 ml of Milli-Q water; add carefully 800 ml of concentrated HCl. The dilution has to be carried out in a well-ventilated fume hood to prevent exposure to toxic fumes released during dissolution of KBrO3. Keep the bottle wrapped in aluminium foil, tightly closed in a double plastic bag, and in an Hg free environment (i.e. laminar flow hood). This solution is stable indefinitely but can become contaminated.

3.10. STANNOUS CHLORINE SOLUTION 20% (w/v) in 20% (w/v) HCl

Weigh 20 g of $SnCl_2$ in a 100 ml volumetric flask; add 20 ml of concentrated HCl; dissolve the $SnCl_2$ (if needed heat at 60°C for a few minutes on a hot plate); complete to 100 ml with water. This solution might be purified by bubbling with Hg-free argon for 15 minutes. The obtained solution should be clear and transparent, cloudy or yellow solution indicates a bad quality $SnCl_2$. This solution should be prepared fresh every day preferably, if not it should be kept in the fridge.

Note: The concentration of this solution is dependent on the type of accessory use for vapour generation, and can vary between 5 and 30%, the recommendation of the manufacturer

should be followed (i.e. the solution above is recommended for a VGA-70 from Varian). The validity of the solution (i.e. shelf-life) should be defined during method validation.

3.11. COMMERCIAL STANDARD SOLUTION 1000 µg ml^{-1}

Use a certified reference material solution; this solution should be accompanied by a certificate stipulating at minimum the traceability of the certified concentration, as well as the expiry date. The density of the solution, or the certified content in mg kg^{-1} should also be defined, to allow for the preparation of the calibration solution by weighing. Stock solutions should be kept at 5°C.

3.12. ARGON

Use of a gas purifier cartridge for removing mercury, oxygen and organic compounds is recommended.

4. MATERIAL

This section does not list the common laboratory glassware.

4.1. ATOMIC ABSORPTION SPECTROPHOTOMETER

Instrument equipped with an appropriate cold vapour generation system and a quartz or glass tube atomizer. Use a hollow cathode lamp or, preferably, an electrodeless discharge lamp (which gives a greater and more stable light intensity), operated at a current recommended for the lamp and by the instrument manufacturer. An AAS system with background correction device is recommended.

4.2. GLASSWARE

All the glassware, polypropylene, or fluorocarbon (PFA or TFM) containers, including the sample bottles, flasks and pipettes tips, should be washed in the following sequence:

- 24 hrs soaking in a laboratory soap (or 10% alcohol);
- followed by 24 hrs soaking in 10% nitric acid;
- followed by 10% soaking in water;
- final rinse in water; and
- drying under a laminar flow hood.

The cleaned items should be kept in a double sealed plastic bag. It is better to avoid storage of low level (< 5 ng ml^{-1}) solution in plastic, and for this purpose glass or Teflon is recommended.

If it can be documented, through an active analytical quality control program, using spiked samples and method blanks, then certain steps in the cleaning procedure would not be needed for routine samples, those steps may be eliminated from the procedure (i.e. for the levels

measured by flame AAS, some sterile plastic containers are sufficiently free of contamination for certain analytes).

4.3. PIPETTES

Some microliter pipettes size ranging from 50 to 10000 µl are needed. The accuracy and precision of the pipettes used should be checked as a routine every 6 months, and the results obtained should be compared with the individual certificates.

4.4. VOLUMETRIC CONTAINERS of suitable precision and accuracy.

5. INTERFERENCES

5.1. IODIDE, GOLD AND SILVER are known interferences for mercury determination by cold vapour. In samples from marine origin (biota or sediment), the levels of those elements are low, and consequently, do not interfere in the measurement process.

5.2. WATER VAPOUR (moisture) should be avoided in the measurement cell, always follow the manufacturer's protocol (e.g. use of membrane drying tube, correct position of gas separator…) and check for absence of moisture in the measurement cell.

5.3. When using GOLD AMALGAMATION, and with certain batch systems, the excess of oxidant can cause interference or damage the gold amalgamator, it is then recommended to pre-reduce the samples with hydroxylamine ammonium (see 3.7). This is important when using large amount of digested solution in "batch system".

5.4. Some samples (i.e. plants or large amount of mussels) might produce FOAM during the reduction reaction. If the amount of foam is important, it can interfere with gas liquid separation, and/or leak in the measurement cell, this phenomenon can be overcome by using silicon anti-foaming inside the gas liquid separator and/or in the "batch" system. Another option is to use vanadium pentoxide during digestion (see 6.4).

5.5. REDUCTION of inorganic mercury will induce loss, so it is important to stabilise all the solutions by using a strong oxidant as dichromate or BrCl (see 3.8 or 3.9).

6. SAMPLE PREPARATION

6.1. The sample should be prepared according to the recommended method for digestion of marine samples for the determination of trace metal (IAEA, 2011), but before diluting to the final volume (or weight) with water, add an adequate volume of potassium dichromate or BrCl to get the final concentration of 2% or 1% respectively. All the samples from marine origin (sediment or biota) can be prepared using the acid mixture recommended for fish, as Hg is not attached to silicates. For microwave digestion of sample size above 0.8 g, it is strongly recommended to do cold digestion for at least 5 hours and to use a long ramping time (i.e. 25 minutes) to avoid strong reactions in the microwave vessels.

6.2. If other trace elements have to be determined in the digested solution prepared according to the recommended method for digestion of marine samples for the determination of trace metal (IAEA, 2011), following the dilution to the final volume or weight, transfer a quantitatively sufficient amount of digested solution (i.e. at least 10 ml) into a separate container (preferably glass or Teflon), and add an oxidising solution 1% (v/v) of BrCl (see 3.9) or 2% (v/v) of potassium dichromate (see 3.8). Record the amount of oxidising solution added in order to calculate the dilution factor (i.e. dilution factor =1.01 for 0.1 ml of dichromate in 10 ml).

6.3. Alternatively, the samples can be digested using a mixture of 5 ml of HNO_3 and 2 ml of H_2O_2 at 90°C for 4 hours on a hot plate. It is recommended to leave the samples in acid at room temperature, for at least 1 hour before heating. The digestion can be performed either in a Teflon or glass closed containers. After cooling, add an adequate volume of potassium dichromate or BrCl to get the final concentration of 2% or 1% respectively, and dilute to the final volume with water (i.e. for 50 ml final volume, add 1 ml of potassium dichromate or 0.5 ml of BrCl solution). This procedure can be used with bigger sample size if needed (i.e. 2 g); in this case, the volume of nitric acid should be increased to obtain a liquid mixture.

6.4. In the case that the digested solution produces foam during the reduction process (see 5.4), 45 mg of vanadium pentoxide should be added in the digestion vessels before addition of the acid mixture, then follow either paragraph 6.1 or 6.3.

7. PROCEDURE

7.1. SAMPLE SOLUTION

Use the sample prepared with one option as described in section 6.

7.2. BLANK SOLUTION

Prepare at least two blank solutions with each batch of sample, using the same procedure than for the samples.

7.3. PREPARATION OF CALIBRATION SOLUTIONS

7.3.1. Before each batch of determination, prepare by the appropriate dilution of 1000 µg ml^{-1} stock standard solution (see 3.11), at least 4 standard solutions and one calibration blank solution, covering the appropriate range of the linear part of the curve. The calibration standards and calibration blank should be prepared using the same type of acid and oxidising solution than in the test portion (the final concentration should be similar).

7.3.2. Calibration solutions should be prepared fresh each day.

7.3.3. If the necessary intermediate stock standard solutions can be prepared in 5% nitric acid and 1% BrCl or 2% $K_2Cr_2O_7$, these solutions should be prepared monthly.

7.3.4. All volumetric material (pipettes and containers) should be of appropriate precision and accuracy, if not available standard solution can be prepared by weighing.

7.4. INSTALLATION OF VAPOUR GENERATOR ACCESSORY

7.4.1. Install the accessory according to the manufacturer's instructions. Certain systems (i.e. VGA from Varian) are designed to be used for hydride generation as well, and require in the instructions to aspirate an extra HCl solution, in the case of stannous chlorine reduction this solution is to be replaced by water. It is recommended to separate the systems used for hydride and for $SnCl_2$ (i.e. use a spare gas liquid separator and Teflon tubing).

7.4.2. Switch on the argon. For on-line system: start the pump, check the aspiration, and verify the gas liquid separator. If needed replace the pump tubing, clean the gas liquid separator by sonication in diluted detergent.

7.4.3. Clean the system by aspirating reagent and 10% nitric acid as a sample for about 10 minutes. For batch system, perform two cycles with 10% nitric acid.

7.4.4. Set up the atomic absorption spectrometer according to the manufacturer's instructions, at the appropriate wavelength, using the appropriate conditions, and with the suitable background correction system in operation.

7.4.5. Optimise the position of the measurement cell to get the maximum signal.

7.4.6. Connect the vapour generation system to the measurement cell.

7.5. CALIBRATION

7.5.1. Adjust the response of the instrument to zero absorbance whilst aspirating water.

NOTE: if the instrument zero reading is more than 0.002 ABS, the system should be clean again and reagent should be checked.

7.5.2. Aspirate the set of calibration solutions in ascending order, and as a zero member, the blank calibration solution. After the last standard, aspirate 10% nitric acid for 1 minute to rinse the system.

NOTE: The calibration curve is automatically plotted by the instrument software. The obtained curve should be linear with r>0.995.

To correct for the instrumental drift, the calibration should be performed every 20 samples or if the calibration verification has failed (see 7.8.1).

7.6. ASPIRATE SAMPLE BLANK (see 7.2) AND SAMPLE SOLUTIONS (see 7.1)

Record their concentrations as calculated by the software using the calibration curve. Rinse the system by aspirating 10% nitric acid for at least 30 s between samples.

7.7. IF THE CONCENTRATION OF THE TEST PORTION EXCEEDS THE CALIBRATION RANGE, dilute the test portion with the blank solution accordingly.

NOTE: After the measurement of high level (or over calibration) sample, measure a sample blank or water to check the absence of memory effect. If necessary, clean the system for 1 minute with 10% nitric acid.

7.8. QUALITY CONTROL SOLUTIONS

The quality control solutions as described below should be measured during the run.

7.8.1. Calibration Verification CV

After the initial calibration, the calibration curve must be verified by the use of initial calibration verification (CV) standard.

The CV standard is a standard solution made from an independent (second source) material, at/or near midrange. This solution as a calibration standard should be prepared using the same type of acid and oxidising solution than in the test portion (the final concentration should be similar).

The acceptance criteria for the CV standard must be ±10% of its true value.

If the calibration curve cannot be verified within the specified limits, the causes must be determined and the instrument recalibrated before the samples are analysed. The analysis data for the CV must be kept on file with the sample analysis.

The calibration curve must also be verified at the end of each analysis batch and/or after every 10 samples. If the calibration cannot be verified within the specified limits, the sample analysis must be discontinued, the causes must be determined and the instrument recalibrated. All samples following the last acceptable test must be reanalysed.

7.8.2. Blank solution (see 7.2)

The maximum allowed blank concentration should be well documented, and if the blank solution exceeds this value all samples prepared along the contaminated blank should be prepared again and reanalysed.

7.8.3. Post digestion spike

Each unknown type of sample should be spiked to check for potential matrix effect.

This spike is considered as a single point standard addition, and should be performed with a minimum dilution factor. The recovery of spike calculated with equation 1 should be 85-115%. If this test fails, it is recommended to run analysis with standard addition method.

Spike solution: mix a fix volume (V1) of the sample solution, and a known volume (V2) of a standard solution with known concentrations (Cstandard).

Unspike solution: mix the same fix volume (V1) of sample solution, and the same volume (V2) of reagent water.

Measure the concentration C (mg l^{-1}) in both solutions on the calibration curve (see 7.6), and calculate recovery as:

$$Cspike = \frac{Cstandard \times V2}{(V1+V2)} \qquad \text{Equation 1}$$

$$R = \frac{C\ Spike\ Solution - C\ Unspike\ solution}{Cspike} \times 100 \qquad \text{Equation 2}$$

To be valid, the concentrations of spiked and unspiked solutions should be in the linearity range of the calibration curve, and the spiked concentration (equation 1) should be in the range of 50-150% of the concentration of the unspiked solution.

7.8.4. Dilution test

If the analyte concentration is sufficiently high (minimally, a factor of 10 above the lower limit of the quantitation following dilution), an analysis of a 1:5 dilution should agree within

±10% of the original determination. If not, then a chemical or physical interference effect should be suspected, and method of standard addition is recommended.

7.8.5. Certified Reference Material

At least one certified reference material of a representative matrix should be prepared with each batch of sample, the calculated result should fall in the value of the certificate and within the coverage uncertainty (Linsinger, 2010), to show evidence of an unbiased result.

The results for the CRM should be recorded for quality control purpose and plotted on a control chart (UNEP/IOC/IAEA 1994).

An example of sequence order with recommended criteria and actions is given in table 1.

TABLE 1. EXAMPLE OF AN ANALYTICAL SEQUENCE:

Solutions Description	Performance	Action
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1–4	r>0.995	recalibrate in the linearity range
CV	±10% of the true value	Stop until resolve
Sample blank	< maximum allowed blank value	
CRM	Fall in the certificate value within coverage uncertainty, or fall within acceptable criteria of the QC chart	Stop until resolve, check Matrix spike and run again with standard addition method if necessary
Matrix Spike	recovery 100% ± 15%	switch to standard addition, keep records for future analysis of the same matrix
Dilution Test	sample 1 = 5x sample 1 diluted 5x within 10%	switch to standard addition, keep records for future analysis of the same matrix
Unknown Sample 1–10	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute
CV	±10% of the true value	Stop until resolve
Unknown Sample 11–20	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1–4	r>0.995	recalibrate in the linearity range
CV	±10% of the true value	Stop until resolve
Etc….		

8. CALCULATION OF RESULTS

Results are calculated using equation 3

$$w(m) = \frac{(\rho 1 - \rho 0)}{\mathrm{m}} \times f \times V \times R \qquad \text{Equation 3}$$

Where:

w(m) is the mass fraction of element m in the sample, expressed in mg kg^{-1};

ρ1 is the concentration of element m, expressed in mg/l as measured in the sample solution;

ρ0 is the concentration of element m expressed in mg/l as measured in the blank solution;

F is the dilution factor calculated as follow:

$$f = \frac{final\ volume}{initial\ volume}$$

or equal to 1 if ρ1 is determined in undiluted solution;

R is the recovery calculated using the CRM (see 7.8.5) or the post digestion spike.

m is the mass of sample in g

V is the volume of solution in ml

9. EXPRESSION OF RESULTS

The rounding of values will depend on the uncertainty reported with the result; in general for this method two or three significant figures should be reported.

Uncertainty component should be reported with all results. (ISO 2005, Nordtest 2004)

Example: w(Hg) = 0.512 ± 0.065 mg kg^{-1}.

Annex VIII:

CEMP Guidelines for Monitoring Contaminants in Sediments

(OSPAR Agreement 2002-16)

Technical Annex 5: Normalisation of contaminant concentrations in sediments

CEMP Guidelines for Monitoring Contaminants in Sediments

(OSPAR Agreement 2002-16)

Technical Annex 5: Normalisation of contaminant concentrations in sediments

1. Introduction

As contaminant concentrations may vary due to differences in bulk sediment composition, e.g. differences in particle size distribution, organic matter content, results from comparisons of observed data to assessment criteria or trend assessments may be obscured. In order to reduce variances of contaminant concentrations due to differences in bulk sediment composition and to increase the power of monitoring programmes to address the objectives of the JAMP, procedures for normalisation of the concentrations of contaminants in sediment have been developed and used in OSPAR assessments of monitoring data.

2. Purposes

This annex provides guidance on the application of methods to normalise contaminant concentrations in sediments. Normalisation is defined here as a procedure to adjust contaminant concentrations for the influence of the natural variability in sediment composition, grain size, organic matter and mineralogy. Most natural and anthropogenic substances, metals and organic contaminants, show a much higher affinity to fine particulate matter compared to the coarse fraction. Constituents such as organic matter and clay minerals contribute to the affinity to contaminants in this fine material.

Fine material, both inorganic and organic, and associated contaminants are preferentially deposited in areas of low hydrodynamic energy, while in areas of higher energy, fine particulate matter is mixed with coarser sediment particles which generally have smaller binding capacity for contaminants. This dilution effect will cause lower and variable contaminant concentrations in the resulting sediment. Obviously, grain size and organic matter are important factors controlling the distribution of natural and anthropogenic components in sediments. It is, therefore, essential to normalise for the effects of grain size or organic carbon in order to provide a basis for reliable assessments of temporal trends and for meaningful comparisons of the occurrence of substances in sediments of variable bulk properties with background (assessment) criteria and environmental assessment criteria derived for a defined sediment composition.

In sediment of varying bulk properties, contaminant concentrations will be closely related to the distribution of fine grained material, and any effects of other sources of contaminants, for example anthropogenic sources, will be at least partly obscured by grain size differences. Also in temporal trend monitoring, differences in sediment bulk properties can obscure trends, but if samples have a considerable and constant percentage of fine material, the influence of grain size distribution is of minor importance and may probably be neglected.

3. Normalisation procedures

Two different approaches to correct for variable sediment compositions are widely used:

a. Isolation of the fine fraction by sieving, e.g. <20 µm, <63 µm, can be regarded as means to reduce the differences in sediment granulometric compositions and is applicable to both metals and organic contaminants (e.g. Ackermann *et al*. 1983; Klamer *et al*. 1990; QUASH, 2000). Consequently the coarse particles, which usually do not bind anthropogenic contaminants and dilute their concentrations, are removed from the sample. Then, contaminant concentrations measured in these fine fractions can be directly compared. Subsequently, the differences in sediment composition due to geochemical nature remaining after sieving can be further corrected for by the use of co-factors. Thus, sieving is a powerful first step in normalisation;

b. Normalisation can be performed by relating the contaminant concentration with components of the sediment that represents its affinity for contaminants, i.e. binding capacity. Normalisation of contaminant concentrations can be performed by linear regression against cofactors (Cato, 1977; Smedes, 1997; Smedes *et al.,* 1997). Another procedure takes into account that the coarse sediment fraction contains natural metal concentrations in the crystal structure before the normalisation is performed (see section 4). Combinations of co-factors, possibly identified from multiple regression analysis, can be used.

4. Normalisation using co-factors

a. The binding capacity of the sediments can be related to the content of fines, primary factor, in the sediments. Normalisation can be achieved by calculating the concentration of a contaminant with respect to a specific **grain-size fraction** such as <2 µm, i.e. the clay factor, <20 µm or <63 µm;

b. As the content of fines is represented by the contents of major elements of the clay fraction such as **aluminium** (Windom *et al*. 1989) or an appropriate trace element enriched in that fraction such as **lithium** (Loring 1991), these can also be used as co-factors, secondary factors. Both, aluminium and lithium behave conservatively, as they are not significantly affected by, for instance, the early diagenetic processes and strong redox effects frequently observed in sediments. Problems may occur when the sediment is derived from glacial erosion of igneous rocks, with significant amounts of aluminium present in feldspar minerals contributing to the coarse fraction. In such cases, lithium may be the preferable co-factor (Loring 1991);

c. Organic matter, usually represented by organic carbon, is the most common co-factor for organic contaminants due to their strong affinity to this sediment component. In some environments, trace metal concentrations can also be normalised using organic carbon content especially in surface sediments (Cato 1977). However, due to the non-conservative nature of organic matter, its suitability as co-factor has to be checked prior to an assessment.

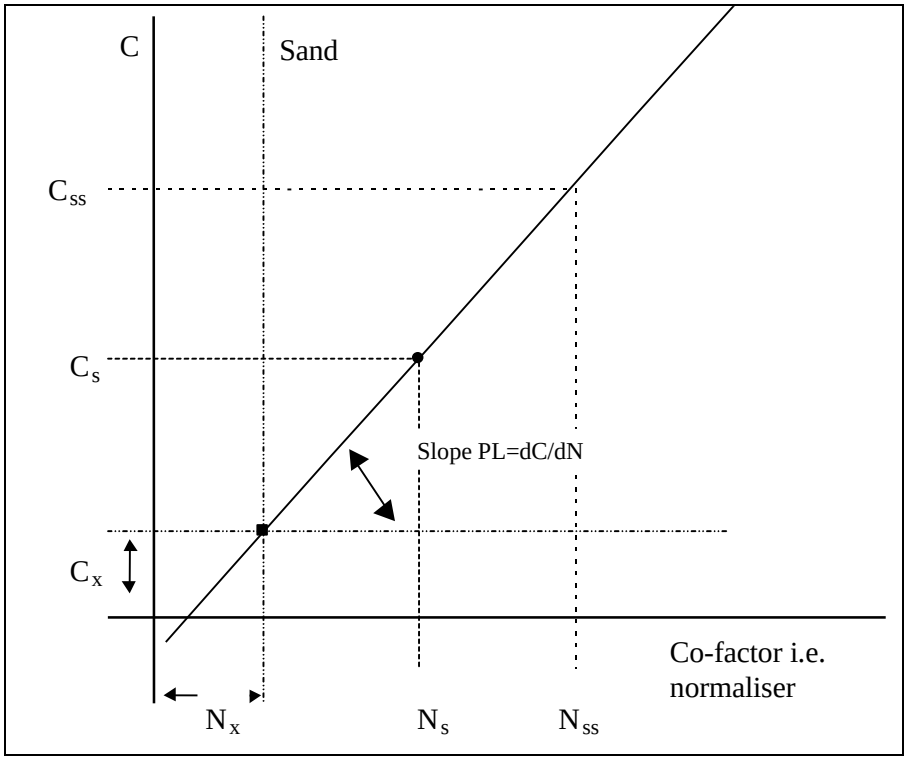

Figure 1: Relationship between the contaminant C and the cofactor N (from Smedes, 1997).

5. Theory

The general model for normalisation taking into account the possible presence of contaminants and cofactors in the coarse material is given in figure 1 (Cato, 1977; Smedes *et al*.1997; Kersten and Smedes, 2002). C_x and N_x represent the contaminant and the co-factor contents, respectively, in pure sand. These "intercepts" can be estimated from samples without fines and organic material. The line of regression between the contaminant and co-factor will originate from that point. That means that regression lines of sample sets with a different pollution level and consequently different slopes will have this point in common (i.e. pivot point) (OSPAR 2008). When this pivot point is known, only one sample is required to estimate the slope. This allows determination of the contaminant content for any agreed (preselected) co-factor content (N_{ss}) by interpolation or extrapolation. The slope (PL) for a sample with a contaminant content C_s and a cofactor content of N_s can be expressed as follows:

$$PL = \frac{dC}{dN} = \frac{C_s - C_x}{N_s - N_x} \quad (1)$$

The extrapolation to an agreed co-factor content, N_{ss}, follows the same slope:

$$PL = \frac{dC}{dN} = \frac{C_s - C_x}{N_s - N_x} = \frac{C_{ss} - C_x}{N_{ss} - N_x} \quad (2)$$

Rewriting gives the contaminant content, C_{ss}, that is normalised to N_{ss}:

$$C_{ss} = (C_s - C_x)\frac{N_{ss} - N_x}{N_s - N_x} + C_x \quad (3)$$

Results of different samples normalised to the agreed N_{ss} can be compared directly.

Normalisation by this model can be applied with different cofactors. Here primary and secondary cofactors can be distinguished. A primary cofactor like the clay fraction or organic carbon is not present in the coarse fraction and consequently has no intercept (N_x=0). Al and Li are present in the coarse fraction and therefore are considered to be secondary cofactors. Provided N_x and C_x are known, the model allows recalculation of total samples to a co-factor content usually found in sieved fractions, either <20 or <63µm. However such an extrapolation for a coarse grained sample will be associated with a large error due to the uncertainty of the intercepts and the analysed parameters. For a more fine grained sample, or a sieved fraction, the uncertainty of the normalised result is much lower than for normalisation of a coarse grained sample to the agreed cofactor content and will result in a more accurate result. The model presented also applies to the normalisation of organic contaminants using organic carbon but in that case the intercepts N_x and C_x will not differ significantly from zero.

Principally, the result allows comparison of data of total and sieved samples, irrespective of the sieving diameter but the error has to be taken into account. Through propagation of errors the standard error of the result can be calculated from the analytical variation and the natural variation of the intercept N_x (Smedes *et al.*, 2005). Results can therefore always be reported with a standard deviation.

6. Considerations on co-factors

The **clay mineral content** is the most important cofactor for trace metals. In the model above the N_x will be zero for clay and only the intercept due to the content of the trace metal in the coarse fraction (C_x) has to be taken into account. However, current intercomparison exercises do not include this parameter. Presently other parameters such as aluminium or lithium are used to represent the clay content.

The **aluminium** content in the sandy fraction may vary from area to area. For some areas aluminium contents in the sandy fractions are found at the same level as found in the fines (Loring, 1991) and therefore the intercept N_x becomes very high. In equation (3) this implies that the denominator is the result of subtracting two large numbers, that is the normaliser content in the sample (N_s) and the normaliser content in only sand (N_x). Consequently, due to their individual uncertainties, the result has an extremely high error. Obviously, normalisation with low intercepts is more accurate. Much lower intercepts are found if partial digestion methods are used that digest the clay minerals, but not the coarse minerals. Using partial digestion, the spatial variability of the results of aluminium analyses in the sandy fraction has been found to be much smaller than with total methods. Although normalising concentrations of contaminants in fine grained material will always give more accurate results, an error calculation will identify whether using coarse samples (and total methods, e.g. HF, X-ray fluorescence, litium tetraborate fusion) allows the requirements of the programme to be met.

For most areas the **lithium** content in the sandy fraction is much lower than in the fine fraction. In addition, results from partial digestion and total methods do not differ significantly. There is only little spatial variability of the lithium content in the sandy fraction. Generally, compared to aluminium, more accurate normalised data can be expected using lithium.

As for clay, no intercept (N_x) applies for organic matter, which is usually represented by **organic carbon**. Organic matter also occurs in the coarse fraction but is even then a cofactor that contributes to the affinity for contaminants, whereas the aluminium in the coarse fraction does not. Furthermore, organic matter in a sample is not always well defined as it can be composed of material with different properties. The most variable properties will be found in the organic matter

present in the coarse fraction and not associated with the fines. In **fine sediments** or in the sieved fine fractions the majority of the organic matter is associated with the mineral particles and it is assumed to be of more constant composition than in the total sample. In addition, the nature of the organic matter may show spatial and temporal variations. For samples with low organic carbon content close to the detection limit, normalisation using this cofactor suffers from a large relative error. This results from the detection limit and the insufficient homogeneity that cannot be improved due to the limited intake mass for analysis.

For further interpretation of data the **proportion of fines** determined by sieving can be useful. Provided, there are no significant amounts of organic matter in coarse fractions, the proportion can be used as a co-factor, particularly for organic contaminants. The error in the determination of fines has to be taken into account and will be relatively high for coarse samples.

7. Considerations on contaminants

Almost all trace metals, except mercury and in general also cadmium, are present in the coarse mineral matrix of samples. The metal concentrations show a spatial variability depending on the origin of the sandy material. In sandy sediments, partial digestion techniques result in lower values than are obtained from total digestion techniques. This implies that partial digestion results in lower intercepts (pivot point is closer to the zero). However, the partial digestion must be strong enough so the clay will be totally digested (as is the case with HF digestion techniques), and the measured aluminium content remains representative for the clay. It was demonstrated that analyses of fine material gave similar results for several trace elements using both total and strong partial methods (Smedes *et al*. 2000; Kersten and Smedes, 2002, cf. Technical Annex 6)

For organic contaminants the situation is more complex. In general, correlations of organic contaminants with organic carbon have no significant intercept, i.e. the contaminants are primarily associated with organic matter. Thus, for sediment samples that contain low concentrations of organic carbon (e.g. very sandy sediments), concentrations of these contaminants can be below or very close to the analytical detection limit. Application of the normalisation procedure using organic carbon to such samples is inappropriate, since it will greatly magnify the analytical error. The influence of these errors can be minimised by analysing muddy sediments, or by analysing a fine fraction sieved from the bulk sandy sediment.

In some cases, PAHs in sediment are found associated with materials such as soot or ash. Concentrations of PAHs can be quite high in these materials, and this can result in high concentrations of PAHs in grain size fractions where soot, ash, etc. are concentrated. These materials generally are present in small quantities, and the PAHs associated with them have little biological activity, and therefore are of limited environmental significance. Although the available data are not comprehensive, existing information indicates that PAH concentrations in sieved fine fractions (e.g. <63 um) are not significantly affected by the presence of small amounts of soot, ash etc.

8. Isolation of fine fractions for analyses

The Sample preparation

Samples should be sieved at 2 mm as soon as possible after sampling to remove large detritus and benthic organisms. Otherwise during further sample handling like storage, freezing or ultrasonic treatment, biotic material will deteriorate and become part of the sediment sample. Until the final sieving procedure that isolates the fines, the sample can be stored at 4°C for about a week and up to

3 months when frozen at –20°C, although direct wet sieving is preferred. For prolonged storage freeze-drying of samples can be considered. In this case contamination and losses of contaminants during freeze-drying have to be checked. Air-drying is not appropriate due to high contamination risks and checks are needed. Besides, samples may be difficult to be disaggregated and mineral structures may be affected.

Requirements for Sieving

A wet sieving procedure is required to isolate the fine-grained fractions, <63 µm or <20 µm. Wet sieving re-suspends fine particles that would otherwise remain attached to coarser particles in the sample. Sediments should be agitated during sieving to prevent to disaggregate agglomerates of fines and to prevent clogging of the mesh. Freeze-dried samples need to be re-suspended using ultrasonic treatment. Seawater, preferably from the sampling site, should be used for sieving as it reduces the risk of physico-chemical changes in the sample i.e. losses through leaching or contamination. Furthermore seawater assists the settling of fine particles after the sieving. If water from the sampling site is not available, then seawater of an unpolluted site, diluted with deionised water to the required salinity, can be used. The amount of water used for sieving should be kept to a minimum and be reused for sieving subsequent batches.

To minimise or prevent contamination it is recommended to use large sample amounts of sediment for sieving. No significant contaminant losses or contamination was detected when at least 25 g of fine fraction is isolated.

Methodology

Both automated and manual methods are available for sieving. A video presentation of these methods can be provided by the QUASH Project (QUASH 1999).

- The automatic sieving method pumps seawater over a sieve that is clamped on a vibrating table (Klamer *et al*. 1990). The water passing the sieve is led to a flow-through centrifuge that retains the sieved particles and the effluent of the centrifuge is returned to the sieve by a peristaltic pump. Large sample amounts, up to 500 g, can be handled easily.
- The second method is a manual system sieving small portions 20-60 g using an 8-cm sieve in a glass beaker placed in an ultrasonic bath (Ackermann *et al*. 1983). Particles are isolated from the water passing the sieve by batch wise centrifugation. The water can be reused for a subsequent batch of sediment. In case of sandy samples, when large amounts of sediments have to be sieved, removal of the coarse material by a pre-sieving over e.g. 200-µm mesh can facilitate the sieving process.

Isolated fine fractions have to be homogenised thoroughly, preferably by a ball mill, as centrifugation produces inhomogeneous samples due to differences in settling speed of different grain-size fractions.

9. Limitations of normalisation

The purpose of normalisation is to reduce the variability between samples arising from differences in bulk sediment properties. However, it has been observed in some areas that the correlations between contaminant and cofactor concentrations may be weak or even absent. This may happen, e.g., if the cofactor used is inappropriate for the contaminant of concern, the degree of contamination is very variable with time or space, or there is significant additional variance arising from the measurements of the concentration of the chosen cofactor.

Contracting Parties may specify additional cofactors other than Al, Li or TOC to be used for the normalisation of concentrations of particular contaminants in their monitoring data. The effectiveness of the normalisation should be accessed through the effect of application of normalisation on the residual variance about time series, as described above. When making proposals, it will be necessary for Contracting Parties to ensure that pivot values and Background Concentrations expressed in relation to the same cofactors are also available.

Current procedures applied in OSPAR trend assessments include the application of smoothers or, for short time series, linear regressions. Normalisation using cofactors should be applied if this results in a reduction of the residual variance around the fitted smoother or regression in time series, but should not be applied if the residual variance is not reduced. In case the residual variance can be reduced for time series, normalisation should also be applied to check whether observed concentrations of contaminants are at or close to Background (Assessment) Concentrations and whether they comply with the Environmental Assessment Criteria.

Furthermore, as the composition of sand-sized material may differ significantly between different parts of the Convention area, **pivot values** (cf. Section 5) can vary too. In addition, they can vary with the analytical method, i.e. with partial or total digestion for metals analysis. The use of inappropriate pivot values could have significant impact on the calculated normalised concentrations (cf. Section 5), particularly for sediment samples containing relatively small proportions of fine grained material. Therefore, Contracting Parties may propose derived pivot values appropriate to particular parts of the Convention area to OSPAR/ICES for review. Such regionalised pivot values should be applicable over large parts of the Convention area, for example across entire (sub-)Regions

The current **Background (Assessment) Concentrations** may be inappropriate for application throughout the Convention area, as they were derived from a data set that emphasises the northern part of the Convention area. In addition, the Background Concentrations are currently expressed as normalised values (to 5% aluminium for metals and 2.5% TOC), and these “reference” values for the cofactors may not be appropriate for all areas. The use of inappropriate values for Background Concentrations could result in misleading assessments, e.g., as to whether concentrations in sediment are at or close to background. Therefore, Contracting Parties may propose derived Background Concentrations and associated cofactor values that they consider to be appropriate to particular parts of the Convention area. OSPAR/ICES will review if the combinations of Background Concentrations and associated cofactor values are consistent with the way in which pivot values to be used in the assessment of the field data are expressed, to allow the construction of straight lines joining pivot values and Background Concentrations. Such regionalised Background Concentrations should be applicable over large parts of the Convention area, for example across entire (sub-Regions)

10. Recommendations

1. For monitoring, it would be ideal to analyse samples with equal composition. This could be confirmed by determination of co-factors Al, Li, TOC and parameters of the grain size distribution (e.g. clay content, proportion <20µm, proportion <63µm). However, this situation will seldom occur.

2. New temporal trend programs should be carried out by the analysis of fine sediments or a fine-grained fraction, isolated by sieving. Existing temporal trend programs could be continued using existing procedures, provided that assessment of the data indicates that the statistical power of the programs is adequate for the overall objectives.

3. Contaminant concentrations in whole sediments can be subjected to normalisation using co-factors for organic matter, clay minerals etc., by taking into account the presence of both co-factors and target contaminants in the mineral structure of the sand fraction of the sediment. Taking into account these non-zero intercepts of regressions of contaminant concentrations with co-factors, normalisation to preselected co-factor content will reduce the variance arising from different grain sizes. Normalised values for sandy sediments will have greater uncertainties than for muddy sediments. The propagated error of the variables used for normalisation may be unacceptably high for sandy sediments, if both contaminant and co-factor concentrations are low, particularly when approaching detection limits. In that case, in order to reduce the overall uncertainty, alternative procedures, such as sieving, need to be used to minimise the impact of this error structure.

4. The natural variance of sample composition will be smaller in the fraction <20 µm than in the fraction <63 µm. Therefore, for trace metals, the fraction <20 µm should be preferred over the fraction <63 µm. However, separation of the fraction <20 µm can be considerably more laborious than the separation of the fraction <63 µm and might be an obstacle to its wide application. For this practical reason, the fraction <63 µm is an acceptable compromise for monitoring programmes. For organic contaminants, the fraction < 63 µm should be used for analyses, as it may be difficult to incorporate the organic matter with the highest binding capacity for organic contaminants in the fine grained fraction < 20 µm completely. Thus, variances due to separating the fine fraction can be reduced.

5. There will still be some residual variance arising from differences in the composition (mineralogy and organic carbon content) of the sediments. Therefore, the preferred approach is analyses of contaminants in fine sediments or in the fraction <63 µm, followed by normalisation of analytical results using cofactors (see section 3). Current scientific knowledge indicates that this procedure minimises the variances arising from differences in grain size, mineralogy and organic matter content. Application of this two-tiered approach to fractions < 20 µm gives results that can be directly compared to results found by normalisation of concentrations measured in fractions < 63 µm.

6. In order to clarify aspects of data interpretation, analytical data for field samples should be accompanied by information on limits of detection and long term precision. In order to contribute to environmental assessment, data for field samples should include the grain size distribution, as a minimum the proportion of the analysed fraction in the original whole sediment. Aluminium (Al) and total organic (TOC) concentrations should be reported for use as potential cofactors. If possible, the determination of Li as an additional potential cofactor is recommended.

7. In order to take into consideration potential regional differences in sediment composition in monitoring contaminants in sediments and its assessment, cofactors others than those mentioned in section 3 may be used. Furthermore, regionalised pivot points for calculating normalised contaminant concentrations as well as regionalised Background (Assessment) Concentrations may be derived for different regions.

Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment

REGIONAL SEAS

UNITED NATIONS ENVIRONMENT PROGRAMME **November 2011**

Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment

Recommended Methods For Marine Pollution Studies 71

Prepared in co-operation with

MEDPOL

NOTE: This recommended method is not intended to be an analytical training manual. Therefore, the method is written with the assumption that it will be used by formally trained analytical chemists. Several stages of this procedure are potentially hazardous; users should be familiar with the necessary safety precautions.

For bibliographic purposes this document may be cited as:

UNEP/IAEA: Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment. Reference Methods for Marine Pollution Studies No 71, UNEP, 2011.

PREFACE

The Regional Seas Programme was initiated by UNEP in 1974. Since then, the Governing Council of UNEP has repeatedly endorsed a regional approach to the control of marine pollution and the management of marine and coastal resources and has requested the development of regional action plans. The Regional Seas Programme at present includes thirteen regions and has over 140 coastal States participating in it (1).

One of the basic components of the action plans sponsored by UNEP in the framework of the Regional Seas Programme is the assessment of the state of the marine environment, its resources and the sources and trends of the pollution and its impact on human health, marine ecosystems and amenities. In order to assist those participating in this activity and to ensure that the data obtained through this assessment can be compared on a world-wide basis and thus contribute to the Global Environment Monitoring System (GEMS) of UNEP, a set of Reference Methods and Guidelines for marine pollution studies are being developed as part of a programme of comprehensive technical support which includes the provision of expert advice, reference methods and materials, training and data quality assurance (2). The Methods recommended for adoption by Governments participating in the Regional Seas Programme.

The methods and guidelines are prepared in co-operation with the relevant specialised bodies of the United Nations system as well as other organisations and are tested by a number of experts competent in the field relevant to the methods described.

In the description of the methods and guidelines, the style used by the International Organisation for Standardisation (ISO) has been followed as closely as possible.

The methods and guidelines published in UNEP's series of Reference Methods for Marine Pollution Studies are not considered as definitive. They are planned to be periodically revised taking into account the new developments in analytical instrumentation, our understanding of the problems and the actual need of the users. In order to facilitate these revisions, the users are invited to convey their comments and suggestions to:

Marine Environmental Studies Laboratory
IAEA Environment Laboratories
4, Quai Antoine 1er
MC 98000 MONACO

which is responsible for the technical co-ordination of the development, testing and inter-calibration of Reference Methods.

CONTENTS

1. SCOPE AND FIELD OF APPLICATION

This reference method is intended for use in monitoring programmes and pilot research studies. The document describes procedures for the isolation of purified fractions amenable for the determination of DDTs and PCBs in marine sediments and marine organisms by capillary GC/ECD. It is assumed that most of the participants in the UNEP Regional Seas Programmes are equipped with advanced high resolution capillary gas chromatographs and will be able to implement most, if not all, of the procedures described in Reference Method No 40, "Determination of DDTs and PCBs by capillary gas chromatography and electron capture detection" (UNEP 1988). Assuming consistent results are routinely being obtained with these methods by the analytical laboratory, the determination of specific compounds (as opposed to generic mixture of PCBs) opens up the possibility not only of identifying environmental "hot spots", but also for characterising sources, elucidating transport pathways and developing data of greater toxicological relevance. The organisation and content of this document, however, deserves further comment. Under the sections devoted to SEDIMENTS and ORGANISMS, subsections are provided relating to procedures for: 1) Sampling, 2) Extraction and 3) Clean-up and fractionation. In each subsection, several alternative procedures are described. These various procedures have been previously tested and are provided to accommodate the range of capabilities in participating laboratories. For example, laboratories which have access to an HPLC may consider the benefits of using HPLC fractionation procedures in lieu of more conventional low pressure column chromatographic method. Participants are generally encouraged to implement the most effective procedures within the constraints of their individual laboratories.

Several other halogenated pesticides and other electron capturing organic compounds may be present in environmental samples and many of these compounds could also be isolated by the methods described here. However, not all residues will be stable to the clean-up procedures applied for the determination of PCBs and DDTs. Consequently, every analyst must test for analyte recovery and analytical reproducibility prior to applying these methods for other analytes on a routine basis. Primary emphasis should be placed on obtaining the cleanest possible purified fraction for capillary GC/ECD analysis so that interferences and misidentification are minimised, if not eliminated.

2. PRINCIPLES

Following collection of sediment or biota samples using appropriate techniques, samples are stored in trace organic free vessels at -20°C until analysis. For analysis, the samples are prepared for solvent extraction. To achieve a satisfactory recovery of the chlorinated hydrocarbons, samples are dried by either desiccation with anhydrous sodium sulphate or by freeze-drying. Lipids are then Soxhlet extracted from sediments using hexane and dichloromethane, and from biota using hexane or petroleum ether. Following initial clean-up treatments (removal of sulphur from sediment extracts and treatment of biota extracts with concentrated sulphuric acid to destroy some interfering lipids), extracts are fractionated using column chromatography. Detailed protocols for absorption chromatographic fractionation are described for both low and high pressure systems, using Florisil and silica gel respectively. (Additional information concerning alternative techniques including gel permeation chromatography is provided).

3. REAGENTS, SOLVENTS, STANDARDS

3.1. Reagents

3.1.1. List of reagents

- Demineralized distilled water produced by distillation over potassium permanganate (0.1 g/l $KMnO_4$) or equivalent quality, demonstrated to be free from interfering substances.
- Detergent.
- Potassium dichromate.
- HCl. 32%.
- Concentrated H_2SO_4 (d 20°C: 1.84 g/ml).
- Sulfochromic cleaning solution made from concentrated sulphuric acid and potassium

dichromate.
- KOH.
- Anhydrous sodium sulphate.
- Copper fine powder (particle size 63µm).
- Carborundum boiling chips.
- Hg.
- Glass wool
- Alumina (200-240).
- Silica gel (60-100).
- Florisil PR (60-100).
- Bio-Beads SX-3 (200-400).
- Sephadex LX-20.

Solvents:
- Hexane, Dichloromethane, Methanol, Pentane, Cyclohexane, Toluene and Ethyl Acetate, all "distilled in glass" quality.

Standards:
- PCB congeners: 29, 30, 121, 198.
- ε HCH.
- Endosulfan Id_4.
- n-C_{14} d_{30}, n-C_{19} d_{40}, n-C_{32} d_{66}.
- Naphthalene d_8.
- Hexamethylbenzene.
- Cadalene: 1, 6-dimethyl-4-(1-methylethyl)naphthalene.
- DDT reference solutions - Prepare a stock solution of the DDT series (pp' DDT, op DDT, pp' DDD, op DDD, pp' DDE, op DDE) by dissolving 50 mg of each compound in 100 ml of hexane. Store stock solution in sealed glass ampoules.
- Other reference solutions - should be prepared if other residues are to be quantified in these procedures.

NOTES:

Working solutions obtained from the stock reference solutions should be prepared on a regular basis depending on their use and stored in clean glass volumetric flasks tightly capped with non-contaminating materials such as Teflon or glass. Extreme care must be taken to ensure that the concentrations of the standards have not altered due to solvent evaporation.

In order to achieve acceptable accuracy for the standard solutions, at least 50 mg of pure individual compound should be weighed and dissolved into 100 ml of hexane. This will give stock solutions of 500ng/µl.

Example of preparation of stock solutions:

Preparation of a stock solution of pp' DDE at approximately 500ng/µl:

The pp' DDE stock solution is prepared by dissolving approximately (but weighed accurately) 50 mg of pp' DDE in hexane in a 100 ml volumetric flask and bringing the volume to exactly 100 ml with hexane. If the actual weight of pp' DDE is 52 mg, then

$$\frac{52\,\text{mg DDE}}{100\,\text{ml solvent}} \times \frac{1000\,\mu\text{g}}{\text{mg}} \times \frac{\text{ml}}{1000\,\mu\text{l}} = \frac{52\,\text{mg DDE}}{100\,\text{ml of solution}}$$

52 mg/100 ml $\Rightarrow$ 0.52 mg/ml $\Rightarrow$ 520 µg/ml $\Rightarrow$ 520 ng/µl

The concentration of the stock solution will be: 520ng/µl

Preparation of an intermediate solution:

Use the stock solution to prepare the intermediate solution. The concentration of pp' DDE intermediate solution should be approximately 5ng/µl. To prepare the 5ng/µl intermediate solution, transfer 1 ml of the pp' DDE stock solution into a 100 ml volumetric flask and dilute with hexane to 100 ml.

$$\frac{1\,\text{ml DDE stock solution}}{100\,\text{ml final volume}} \times \frac{520\,\text{ng DDE}}{\mu\text{l}} = \frac{5.2\,\text{ng}}{\mu\text{l intermediate solution}}$$

The concentration of the intermediate solution will be: 5.2 ng/µl

Preparation of the working solution:

Use the intermediate solution to prepare the working solution. The concentration of pp' DDE in the working solution could be approximately 50pg/µl.

To prepare the 50 pg/µl working solution, transfer 1 ml of the pp' DDE intermediate solution into a 100 ml volumetric flask and dilute with hexane to 100 ml.

$$\frac{1\,\text{ml DDE intermediate solution}}{100\,\text{ml final volume}} \times \frac{5.2\,\text{ng}}{\mu\text{l}} \times \frac{1000\,\text{pg}}{\text{ng}} = \frac{52\,\text{pg}}{\mu\text{l working solution}}$$

The concentration of the working solution will be: 52 pg/µl

3.1.2. Cleaning of solvents

All reagents, including the distilled water should be of analytical quality. Commercially available solvents like acetone, acetonitrile, dichloromethane, hexane and pentane are invariably contaminated with ECD-active substances; their concentrations vary from batch to batch and with supplier. Reagent quality should be checked by injection of 2 µl of a 100 ml batch of solvent, after concentration to 50 µl in a rotary evaporator. No peak in the GC-ECD chromatogram (90 - 250 °C) should be larger than that for 1pg of lindane. Otherwise, the solvent must be distilled. The following procedure has been found to be both efficient and cost effective, as it allows the use of technical grade solvents as the basic material (reducing the cost by one order of magnitude). 130 - 150 cm height columns are required; the packing material must be glass (to allow subsequent cleaning with an oxidising acid). The entire equipment is cleaned prior to use by 2 consecutive distillation procedures with 500 ml water in each case. It is essential that a current of nitrogen gas (15 ml/min) flows from the distillation flask during distillation of the organic solvents: the condenser serves as exhaust. Ambient air is not in contact with the solvent in this way. Problems are associated with other methods of excluding room air (e.g., active carbon or molecular sieves), the most important one being discontinuity. The condensate is distilled into a 1 litre flask at a 1:20 ratio. This large volume allows for direct transfer into the appropriate solvent containers which should be made of glass and of a sufficient size to provide solvent for not more than 6 analyses. A bottle with sufficient solvent for 10 - 15 analysis has to be opened and closed many times and even when kept closed, when not in use, contamination from the surrounding atmosphere takes place. For more detailed information, consult the Reference Method No 65: UNEP/IOC/IAEA: Reagent and laboratory ware clean-up procedures for low-level contaminant monitoring.

3.1.3. Cleaning of reagents and adsorbents

3.1.3.1. Cleaning of reagents

Powdered or crystalline reagents, such as anhydrous sodium sulfate (Na_2SO_4)*, potassium hydroxide (KOH), glass wool * and carbon or carborundum boiling chips *, must be thoroughly cleaned before use. They should be extracted with hexane in a Soxhlet apparatus for 8 hours and then with methanol or dichloromethane for another 8 hours. For those items indicated by an *, this will require pre-combustion in a muffle furnace at approximately 400°C.

3.1.3.2. Cleaning of adsorbents

Silica gel, alumina and Florisil have to be solvent extracted. Each reagent is first refluxed with methanol or dichloromethane in a Soxhlet apparatus for 8 hours, then with n-hexane for the same period. The solvent is removed by a rotary evaporator operating at low speed, until the sorbent starts falling down as fine particles. Reagents are dried in a drying oven at 0.01 mbar. If this is not available, they are dried in a normal oven at 120°C for 4 hours. This serves to activate silica and alumina. Florisil has to be activated at 130°C for 12 hours. The sorbent is allowed to cool in the oven (if possible under vacuum to avoid uptake of contaminants from the atmosphere) or alternatively, in a dessicator. As active sorbents attract water and contaminants from the atmosphere, controlled deactivation should be carried out by adding water to the fully active sorbent (5% by weight to silica, 2% by weight to alumina, and 0.5% by weight to Florisil). The deactivation procedure should be carried out by adding the water to the sorbent and mixing by gentle shaking for a few minutes. The equilibration takes one day. The activity can be maintained for longer periods of time by sealing the required amount of sorbent in glass ampoules. Otherwise, the activation/deactivation has to be done the day before use.

3.2. Apparatus and equipment

The laboratory used for organic trace analysis must be a dedicated facility, isolated from other projects that could be sources of contamination. It must be properly constructed with fume hoods and benches with electric sockets that are safe for use with flammable solvents. The laboratory must have extractors and rotary evaporators cooling water to run the stills. In tropical regions and in dry climates, a refrigerated re-circulating system should be used to reduce temperatures to the required levels and/or to conserve water. Stainless steel or ceramic tiles make good non-contaminating surfaces. If necessary, benches can be coated with a hard epoxy resin and walls can be painted with epoxy paint. A sheet of aluminium foil on the workbench provides a surface which can be cleaned with solvent. A vented storage facility for solvents is essential. Benches must be fitted with frames to hold stills, extractors, etc. The emergency cut-off switch should be accessible from both inside and outside the laboratory. Fire fighting equipment should be mounted in obvious places and laboratory personnel trained in their use.

3.2.1. List of materials

- A coring device with liners and plunger or a grab sampler (thoroughly cleaned with detergents and solvents before use).
- Glass jars and aluminium foil, stainless steel knives, scoops, forceps, labels, marking pens, logbook.
- Insulated plastic boxes for transporting samples. Ice or dry ice.
- Deep freezer (-18 to -20°C) for sample preservation (frost free type freezers heat to above zero during frost removal cycles and they cannot be used for long term storage).
- Rotary evaporator.
- Kuderna-Danish (or similar) concentrator and heater.
- Soxhlet extraction apparatus and heaters.
- Glassware including boiling flasks, ground glass stoppers, beakers, Erlenmeyer flasks, separatory funnels, centrifuge tubes, weighing bottles, pipettes, tissue grinders.
- Drying oven (temperature range up to at least 300°C) for determining sample dry weights, baking of contaminant residues from glassware and reagents.

Note: A muffle furnace is better for baking materials at greater than 300°C, if required.

- Centrifuge and tubes.
- Freeze-dryer and porcelain pestle and mortar.
- Analytical balance with an accuracy of 0.1 mg and an electro-balance with an accuracy of at least 1 µg.
- Stainless steel tweezers and spatulas.

- Dessicator - completely free of organic contamination and with no grease applied to sealing edges.
- Supply of clean, dry nitrogen.
- Columns for silica gel, alumina and Florisil chromatography.
- Mechanical blender (food mixer).
- Vacuum pump (water-jet air pump).

3.2.2. Cleaning of glassware

Scrub all glassware vigorously with brushes in hot water and detergent. Rinse five times with tap water and twice with distilled water. Rinse with acetone or methanol followed by hexane or petroleum ether. Bake overnight in an oven at 300 °C. All glassware should be stored in dust free cabinets and tightly sealed with pre-cleaned aluminium foil when not in use. Ideally glassware should be cleaned just before use.

For more detailed information, consult Reference Method No 65: UNEP/IOC/IAEA: Reagent and laboratory ware clean-up procedures for low level contaminant monitoring.

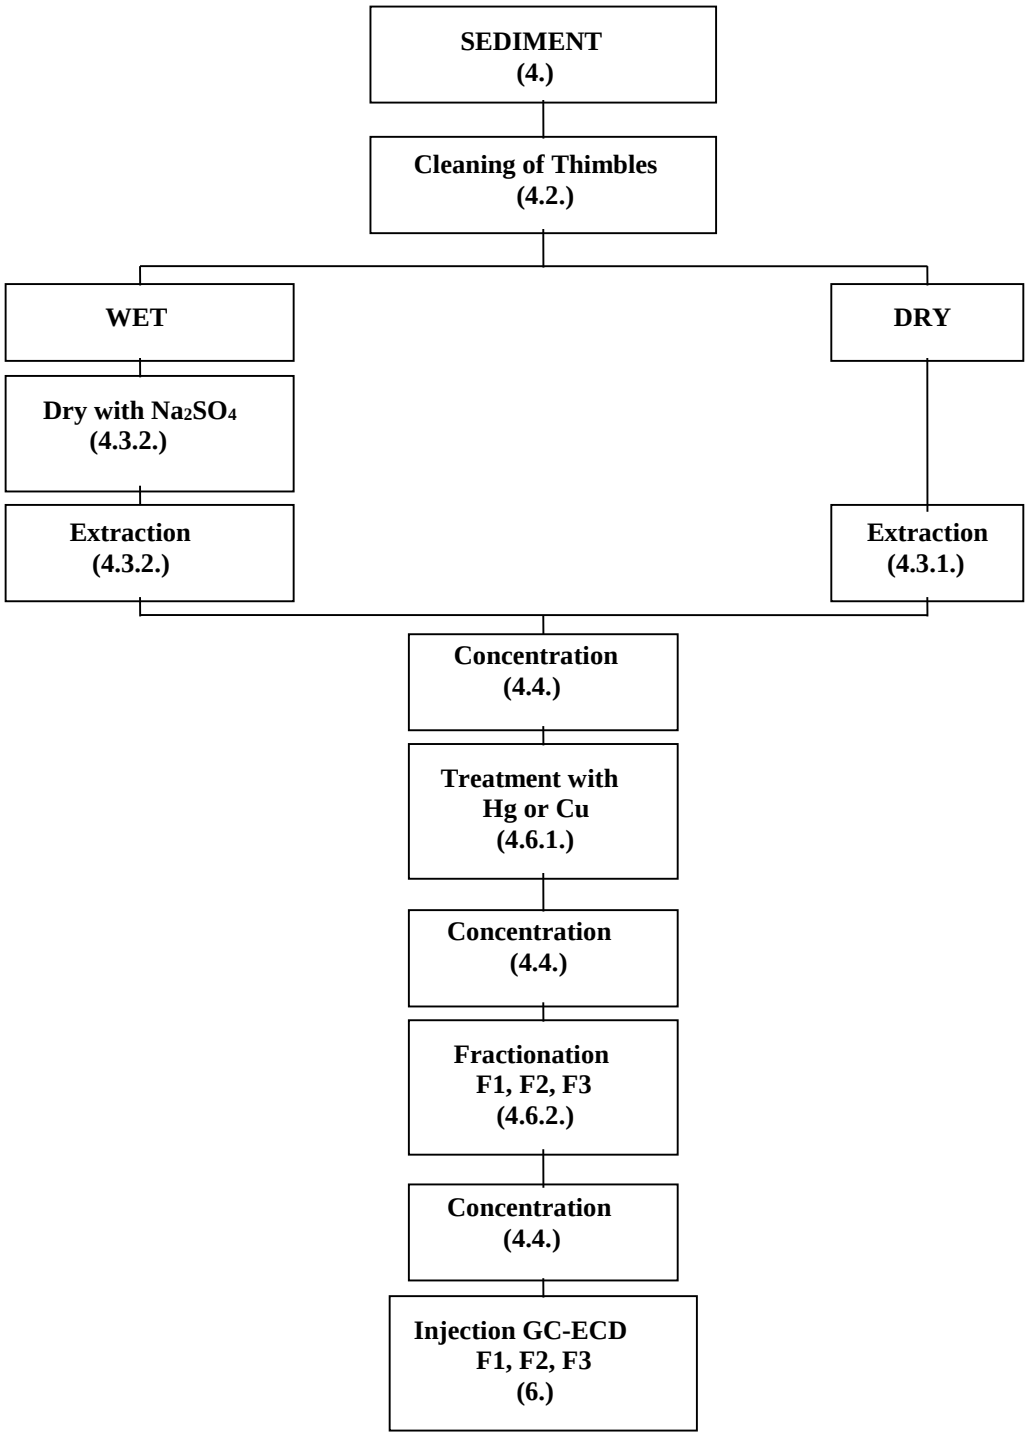

Diagram of the extraction procedure for sediment samples.

4. SEDIMENTS

4.1. Sampling

For the preparation of the samples (including selection of sites, collection of samples and storage) the reader should refer to the Reference Method Nº 58: Guidelines for the use of sediments for the marine pollution monitoring programmes, to the Reference Method Nº 20: UNEP/IOC/IAEA: Monitoring of petroleum hydrocarbons in sediments and to UNEP(DEC)/MEDW.C282/Inf.5/Rev1: Methods for sediment sampling and analysis (2006).

4.2. Cleaning of extraction thimbles

Paper extraction thimbles should be cleaned prior to sample extraction. For use in the extraction of sediment samples, the extraction can be performed in the Soxhlet apparatus with 250 ml of a mixture hexane / dichloromethane (50:50) for 8 hours cycling the solvent through at a rate of 4 to 5 cycles per hour. Add into the solvent a few carborundum boiling chips to get a regular ebullition.

The use of disposable paper thimbles for the extraction procedure rather than re-usable glass fibre thimbles is recommended due to the difficulties encountered in cleaning the latter.

4.3. Extraction of sediments

4.3.1. Extraction of freeze-dried samples

Select a 50-100 g sub-sample of the sediment, weigh this sub-sample and freeze-dry it. When dried, re-weigh it and calculate the dry to wet ratio. Then pulverise the sample using a pestle and mortar and sieve it using a 250 µm stainless steel sieve. Accurately weigh about 20 g of ground sample and place it in the pre-cleaned extraction thimble. Add 1 ml of a solution of 25 pg/µl of 2,4,5 trichlorobiphenyl (PCB Nº 29), 20.9 pg/µl of 2,2',3,3',4,5,5',6 octachlorobiphenyl (PCB Nº 198), 20 pg/µl of ε HCH and 21 pg/µl of Endosulfan Id_4 as internal standards and extract for 8 hours in a Soxhlet apparatus with 250 ml of a mixture hexane / dichloromethane (50:50), cycling the solvent through at a rate of 4 to 5 cycles per hour, add into the solvent a few carborundum boiling chips to get a regular ebullition. Alternatively (or in addition), PCB congeners No 30, 121, or octachloronaphthalene and PCB congeners can be used as internal standards. Prepare a procedural blank by extracting an empty thimble using the same procedure as for the samples.

4.3.2. Extraction of wet samples

The sediment is thawed, sieved at 250 µm and homogenised manually with a stainless steel spatula or clean glass rod. A sub-sample of 1-2 g is weighed into a flask and placed in a drying oven at 105 °C for 24 hours, then allowed to cool to room temperature and re-weighed. Calculate the dry to wet ratio and discard the dry sediment (unless it is being used for other analysis e.g. TOC, total organic carbon).

Place a 30-40 g sub-sample of thawed, homogenised sediment into a blender. Slowly, add 100g of anhydrous sodium sulphate (desiccant) and blend the mixture at high speed for 10 minutes. Transfer the dried sample quantitatively to the pre-cleaned extraction thimble in the Soxhlet apparatus, add the internal standard solution (see above) and apply the same extraction procedure as above. Extract the same amount of sodium sulphate as a procedural blank, making sure to add an appropriate amount of internal standard solution.

4.3.3. Example of determination of percent moisture

Many environmental measurements require the results to be reported on a dry weight basis. The percent moisture or water content in the sample is determined by weighing an aliquot, not used for analysis, of the sample before and after drying. The drying can be done by heating a few grams (1-2 g) of the sample in an oven to constant weight.

Weigh an empty glass beaker that will be used to hold the sample while it is dried.
Empty beaker weight = 10.4417 g

Add the wet sample to the beaker and reweigh. Calculate the wet weight of the sample.
Empty beaker weight + wet sample = 12.2972 g
Wet sample weight = 12.2972 g - 10.4417 g = 1.8555 g

Dry the sample to constant weight: dry the sample for 24 hours, weigh it, dry again for 12 hours, re-weigh it, when the difference in weight is less than 5%, it means that the sample is dried.
Empty beaker weight + dry sample weight = 10.9396 g
Dry sample weight = 10.9396 g - Empty beaker weight
Dry sample weight = 10.9396 g - 10.4417 g = 0.4979 g

Calculate the percent dry sample weight.

$$\% \text{ Sample weight} = \frac{\text{Sample dry weight}}{\text{Sample wet weight}} \text{ X } 100$$

$$= \frac{0.4979}{1.8555} \text{ X } 100 = 26.8 \%$$

Calculate the percent moisture.

Water content = wet weight - dry weight
= 1.855 g - 0.4979 g = 1.3576 g

$$\% \text{ Moisture} = \frac{\text{Sample water weight}}{\text{Sample wet weight}} \text{ X } 100$$

$$\% \text{ moisture} = \frac{1.3576}{1.8555} \text{ X } 100 = 73.2 \%$$

4.4. Concentration of the extract

For both extraction procedures, the extracts are concentrated in a rotary evaporator to about 15 ml. Under good vacuum conditions the temperature of the water bath must not exceed 30 °C. Dry the extract with anhydrous sodium sulphate (when the sodium sulphate moves freely in the flask it means that the extract is dried). Collect the dried extract in the graduated tube of a Kuderna-Danish concentrator. Concentrate the extract to approximately 5 ml with the Kuderna-Danish concentrator and adjust the volume to exactly 1 ml by evaporating excess solvent under a gentle stream of clean dry nitrogen. The sample extract will be analysed gravimetrically for extractable organic matter (EOM) content at the 1 ml volume as a starting point. If measurements of the EOM are outside the calibration range of the balance, the total volume of the extract is adjusted accordingly using either dilution with hexane or evaporating under a stream of nitrogen gas.

4.5. Extractable organic matter

Before carrying out the clean-up procedure, it is advisable to determine the extractable organic matter.

The EOM is determined in the following manner. On the weighing pan of an electro-balance, evaporate a known volume of the sediment or biota extract (up to 100 µl) and weigh the residue with a precision of about ± 1 µg. If the residue is less than 2 µg, pre-concentration of the original extract is required. The quantity of EOM is:

$$\text{EOM (µg/g)} = \frac{\text{Weight of residue (µg) x volume of the extract (ml) x 1000}}{\text{Volume evaporated (µl) x quantity of sample extracted (g)}}$$

Note that extreme care must be taken to ensure balance and pans are clean, dry and stable to obtain accurate readings at the ± 1 µg level. A small hot plate is used to warm pans and forceps and thus keep these instruments dry after solvent cleaning. If no electro-balance is available, a known volume of the extract can be transferred into a clean pre-weighed beaker. The solvent is evaporated with dry and clean nitrogen until a constant weight of about 1 mg is reached. Calculate the amount of "lipids" in the sample taking into account the volume of the lipid extract which was dried.

Example of calculation of E.O.M.

The extractable organic matter content of a sample is operationally defined as the weight of material extracted with the solvent employed (H.E.O.M. in case hexane is used as solvent). An aliquot of the sample extract is taken (few µl), the solvent is evaporated and the residue is weighed to determine the quantity of lipids extracted in the aliquot and from it to the total sample. The results are normally reported in mg lipids per gram dry weight extracted.

A 1 µl aliquot is removed from a 2.5 ml sample extract for determination of E.O.M. The 1 µl aliquot is evaporated on the pan of an electro-balance and the residue is weighed. Three determinations are made and the average taken.

Measurements:
Sample dry weight extracted: 4.443 g
Total volume of the extract: 2.5 ml
Sample aliquot removed: 1 µl
(1) Weight of a 1 µl aliquot after solvent evaporation: 32.2 µg
(2) Weight of a 1 µl aliquot after solvent evaporation: 32.1 µg
(3) Weight of a 1 µl aliquot after solvent evaporation: 32.3 µg
Average weight of a 1 µl aliquot : 32.2 µg

Total volume of the extract: 2.5 ml

Total quantity of lipids in the sample:

$$32.2\ \text{µg/µl} \times 2.5\ \text{ml} \times \frac{1000\ \text{µl}}{\text{ml}} = 80500\ \text{µg or: } 80.5\ \text{mg}$$

With 4.443 g of sample extracted:
80.5 mg/ 4.443 g = 18.1 mg lipids/g

4.6. Clean-up procedure and fractionation

Purposes of the clean-up: removal of lipids, whenever present at a significant amount; removal of elementary sulphur and sulphur compounds. Both these compound classes can interfere with the gas-chromatographic separation.

4.6.1. Sulphur and sulphur compounds removal

Elementary sulphur and sulphur compounds such as mercaptans should be removed from the extract. This could be done by using either mercury or activated copper.

a) Mercury method.

Add one drop (a few ml) of mercury to the sediment extract and shake vigorously for one minute. Centrifuge and carefully recover and transfer the extract in another tube with a Pasteur pipette. If the mercury is still tarnished, repeat the treatment with another drop of mercury, shake, transfer the hexane into another tube. Repeat this treatment until the mercury stays brilliant in the extract. Rinse the mercury with 5 ml of hexane and combine the extracts. Then, concentrate the resulting solution to ca. 1 ml with a gentle stream of nitrogen.

Cleaning of mercury:

Caution: When removing mercury from the sample, always use a plastic tray to keep the glassware in and work under a fume hood.

Fit a folded filter paper in a 10 cm diameter conical glass funnel and fix the funnel over a 250 ml glass beaker. Using a needle, make a small hole in the bottom of the filter paper. Carefully put the mercury onto the funnel. The mercury flows through the small hole in the filter paper leaving the solid impurities on its surface. The mercury collected is washed three times by shaking it carefully with dichloromethane and by removing dichloromethane layer with the help of a clean glass syringe. Allow the rest of dichloromethane evaporate and store the clean mercury in a thick walled glass bottle with a ground glass stopper. In order to avoid escape of mercury vapour, store the mercury under methanol.

Another way of cleaning the mercury involves sucking the dirty mercury through a capillary tube, such as a Pasteur pipette, connected to a guard-flask and then to a vacuum pump. The mercury will pass through the Pasteur pipette and will be collected and cleaned in the guard-flask. Then it should be transferred into a thick wall glass bottle with a ground glass stopper. The mercury is covered with a layer of methanol to protect it from oxidation.

b) Activated copper method.

Transfer about 20 grams of the copper powder in an Erlenmeyer. Add enough concentrated HCl to cover the copper powder, agitate. Sonicate for 10 min., agitate, put again in ultrasonic bath and sonicate for 10 min. Throw the used HCl, add some fresh HCl, transfer in ultrasonic bath and sonicate for 20 min. repeat that procedure four times in total. Wash with distilled water, agitate, discard, add water again, transfer in ultrasonic bath and sonicate for 15 min., discard the used water, repeat that procedure again, up to pH neutral. Wash with acetone, agitate, transfer in ultrasonic bath and sonicate for 15 min. repeat that procedure four times in total. Then use the same procedure with hexane as a solvent.
Keep in hexane (use it immediately, avoids Cu to be in contact with air).

Transfer 3 to 4 Pasteur pipettes per sample in the flasks containing the hexane extracts. Let the copper react all night. The presence of sulphur compounds in the sample will be detected by the tarnishing of the copper powder. Then, concentrate the resulting solution to ca. 1 ml with a gentle stream of pure nitrogen.

4.6.2. Fractionation

An adsorption chromatography step is used to remove interfering lipids and to fractionate the extract into classes of compounds. Many variations of adsorption chromatography clean-up procedures have been published to date. Four procedures are reported here in order of increasing complexity.

Preparation of the columns: Glass burettes (1 cm diameter) with Teflon stopcocks make convenient adsorption columns. The column is plugged with pre-cleaned cotton or glass wool. Prepare separate columns for each sample and blank determination. The column is partially filled with hexane. The appropriate amount of sorbent is mixed with hexane in a small beaker to form a slurry. A glass funnel and a glass rod are used to pour the adsorbent into the column. Several rinses with hexane are necessary to fill the column to the desired height. Tap with a pencil or a hard silicone tube against the column in order to settle the adsorbent into an even bed. Flush the material adhering to the wall of the column down to the bed with solvent. Prepare each column freshly immediately before use. Never let the column get dry.

4.6.2.1. Florisil

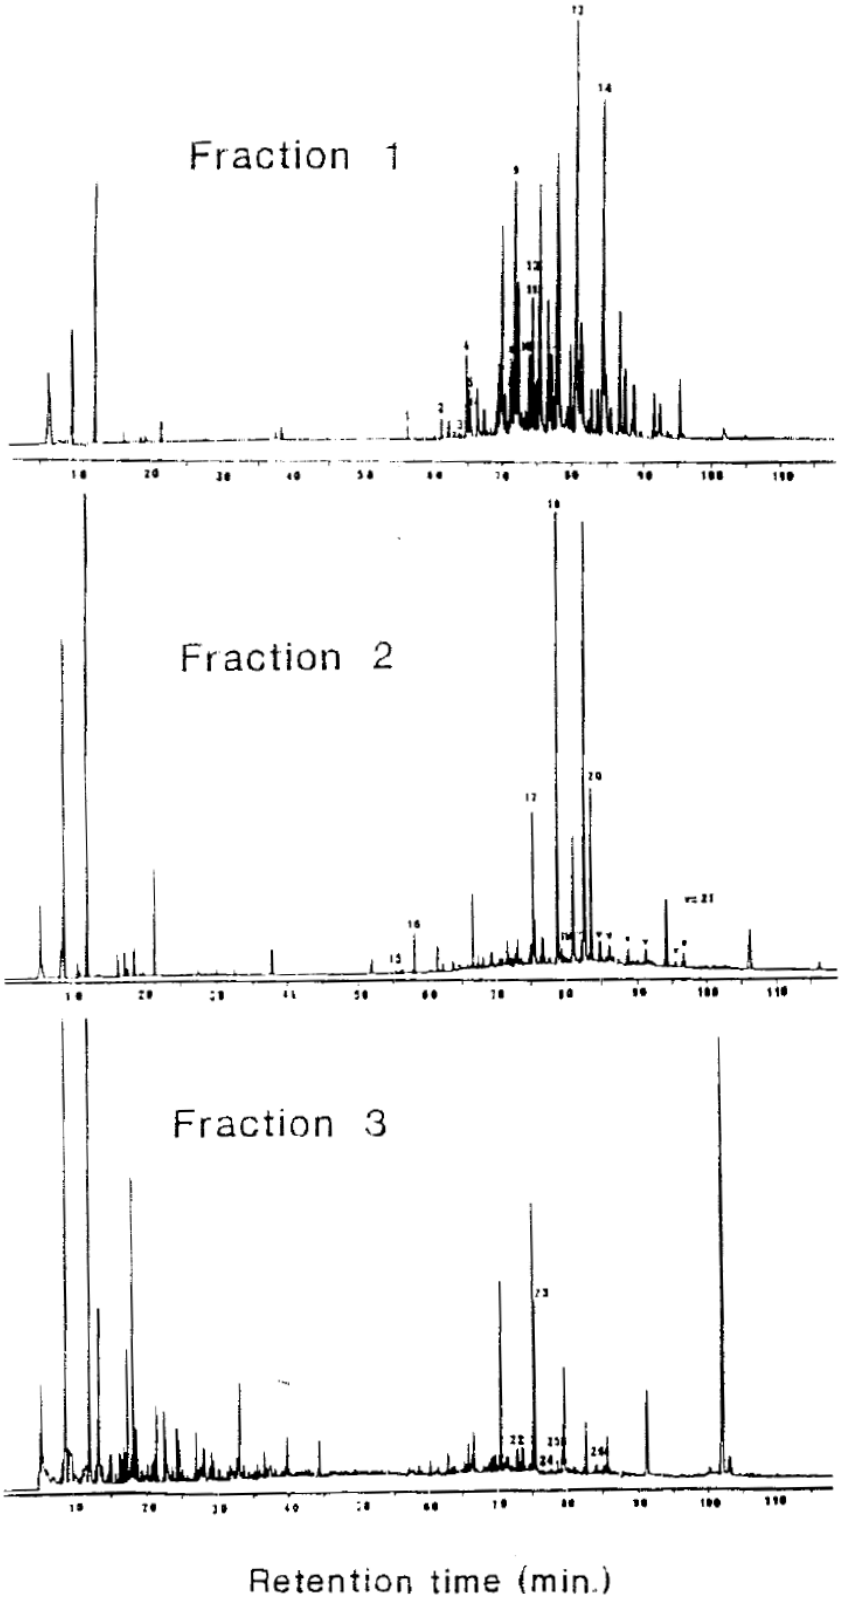
A Florisil column is used for this fractionation, which is prepared in the following way. The Florisil should be pre-extracted in the Soxhlet apparatus to remove any contaminants, using methanol or dichloromethane for 8 hours, followed by hexane for another 8 hours. It is then dried in an oven. Activation is achieved by heating the dried Florisil at 130°C for 12 hours. It is then partially deactivated with 0.5% water by weight and stored in a tightly sealed glass jar with ground glass stopper. The water should be well mixed into the Florisil and the mixture should be allowed to equilibrate for one day before use. The activation/deactivation procedure should be carried out one day before use. A 1 cm burette with Teflon stopcock is plugged with pre-cleaned glass wool. A column with a sintered glass disk could also be used. 17 grams of Florisil are weighed out in a beaker and covered with hexane. A slurry is made by agitation and poured into the glass column. The Florisil is allowed to settle into an even bed and any Florisil adhering to the column is rinsed down with hexane. The solvent is drained to just above the Florisil bed. It should be rinsed with a further 5 ml of hexane; one gram of anhydrous sodium sulphate is added to the top of the column in order to protect the surface of the Florisil from any disturbance. The column should never run dry. Individual columns should be prepared immediately before use and a new column of Florisil used for each sample.

The extract, reduced to 1 ml, is put onto the Florisil column. It is carefully eluted with 65 ml of hexane and the first fraction collected. Then the column is eluted with 45 ml of a mixture containing 70 % of hexane and 30 % of dichloromethane and the second fraction collected. The third fraction will be eluted with 60 ml of pure dichloromethane.

Fraction one will contain the PCBs, pp’ and op DDE and some other pesticides such as HCB, aldrin, heptachlor, DDMU.

Fraction two will contain the DDTs, DDDs, most of the toxaphene, and some pesticides such as the HCH isomers and chlordane components.

Fraction three will contain mainly dieldrin, endrin, heptachlor epoxide and endosulfan components. Typical chromatograms obtained are shown below.



Peak Number	Compounds
1	H.C.B
2	Internal Standard 2, 4, 5 trichlorobiphenyl (IUPAC No : 29)
3	Heptachlor
4	2,2',5,5' tetrachlorobiphenyl (IUPAC No : 52)
5	2,2',4,5' tetrachlorobiphenyl (IUPAC No : 49)
6	Aldrin
7	DDMU
8	op DDE
9	2,2',4,5,5'pentachlorobiphenyl (IUPAC No : 101)
10	2,2',3',4,5 pentachlorobiphenyl (IUPAC No : 97)
11	pp' DDE
12	2,2',3,3',6,6' hexachlorobiphenyl (IUPAC No : 136)
13	2,2',4,4',5,5' hexachlorobiphenyl (IUPAC No : 153)
14	2,2',3,4,4',5' hexachlorobiphenyl (IUPAC No : 138)
15	Alpha-HCH
16	Lindane
17	op DDD
18	pp' DDD
19	op DDT
20	pp' DDT
21	Toxaphene
22	Alpha-endosulfan
23	Dieldrin
24	Endrin
25	Beta-endosulfan
26	Endosulfan sulfate

Figure 2: GC-ECD organohalogen analyses

4.6.2.2. Gel permeation chromatography

Low pressure GPC can be used as an alternative clean-up technique to remove high molecular weight co-extractable lipidic material from polycyclic aromatic compounds and halogenated aromatics. Concurrently, elemental sulphur could be also removed from the whole organic extract.

The main feature of the semi-preparative-GPC as a clean-up technique relies on the compatibility of this analytical procedure with labile components of the extract (i.e. DDTs, chlorinated cyclohexadiene derivatives), which are not stable in other types of extract clean-up procedures. Further, GPC as a clean-up technique has already been automated, enabling a high sample throughput, taking into account the short analysis time involved.

The GPC retention mechanism may involve adsorption, partition and size exclusion mechanisms. The predominance of one mechanism over the others is largely determined by the choice of the mobile phase and the pore size of the packing. In the case of GPC packings with large pore size (1000-2000 daltons) size exclusion and adsorption mechanisms prevail (Bio-Beads SX-3 using cyclohexane, dichloromethane-hexane, dichloromethane-cyclohexane, toluene-ethylacetate and ethylacetate-cyclohexane) (Ericksson *et al*., 1986). On the other hand, when smaller pore sizes (400 daltons) are used in combination with highly polar solvents, (THF, DMF) size exclusion predominates (Lee *et al*., 1981). While using the first approach, a chemical class fractionation could be obtained, however, if smaller pore sizes are used it should be combined with another fractionation technique (i.e. adsorption chromatography) to achieve this selectivity. It has yet to be demonstrated that using GPC as a single clean-up step produces a completely clean extract for GC-ECD determination. Nevertheless, taking into account the increasing availability of high-resolution low molecular weight exclusion packings, they could definitively integrate fractionation and clean-up in a single step.

Low resolution packing (Sephadex LH and Bio-Beads SX, 200-400 mesh size) are the most widely used because they are inexpensive and afford relatively high sample loading (500 mg in 10 mm i.d. columns). The implementation of low resolution GPC requires a solvent delivery system and a UV detector and may be useful. For method development, it is advisable to inject a broad range of standard compounds covering the whole range of molecular weights of the analytes to be determined in order to determine the cut-off points to fractionate real samples. Reported recoveries of PCBs and PAHs range from 60 to 80 % for the concentration level (ng) injected. (Fernandez and Bayona, 1992).

4.6.2.3. Alumina and HPLC (silica column)

The first step in this clean-up procedure is an adsorption step using an alumina column to remove most of the lipid material. Prepare an alumina column (4 x 0.5 cm i.d., made from a Pasteur pipette). Apply the concentrated extract to the top of the column and elute with 10 ml hexane. Concentrate the eluate to about 200 µl. It is followed by a second step to more completely remove interfering compounds and at the same time to separate the compounds of interest into different fractions, containing aliphatics, PCBs, PAHs, pesticides and toxaphene. Between 20 and 200 µl of the extract (after alumina clean-up) are eluted on a stainless steel column (200 x 4 mm i.d.), packed with Nucleosil 100-5 with n-pentane, 20 % dichloromethane in n-pentane and finally dichloromethane. The eluate is collected in fractions containing 1) n-hydrocarbons, 2) PCBs, 3) PAHs and toxaphene, 4) pesticides and toxaphene and 5) acids, etc. (polar compounds). The size of the fractions has to be determined with standard solutions containing the compounds of interest, collecting the eluate in 0.5 ml fractions. Each fraction is then analysed by GC-ECD. Full details have been given in the literature (Petrick *et al*., 1988 and IOC, 1993).

4.6.2.4. High pressure chromatography

High pressure liquid chromatography (HPLC) columns packed with microparticles are available and have the advantages of high reproducibility, low consumption of solvents, high efficiency and high sample loading capacity.

This method can be used to separate fractions containing aliphatic hydrocarbons, PCBs and aromatic hydrocarbons from interfering compounds. These fractions can then be analysed separately for their constituents by GC-FID and/or GC-ECD.

HPLC methods have been developed using synthetic solutions of n-alkanes, PAHs, pesticides, PCBs and toxaphene and have been applied to samples in which interfering substances were present in such high concentrations as to render the analysis of HC and PCBs extremely difficult without this clean-up procedure (e.g. sediments and biological tissues with OCs in the ng/g range). The samples are eluted with n-hexane, subjected to clean-up over alumina, concentrated down to 20-200 µl and treated by HPLC. With the use of n-hexane, n-pentane and 10 %, 20 % and 50 % dichloromethane in n-hexane, respectively, the following five fractions are obtained : 1) n-hydrocarbons and alkenes, 2) PCBs and alkylbenzenes, 3) PAHs and toxaphene, 4) pesticides, 5) acids, etc.(polar compounds). (Petrick *et al*. 1988).

5. BIOTA

5.1. Sampling

Organisms accumulate many contaminants from their environment (i.e., from sea water, suspended particulate matter, sediment and food). Field and laboratory studies have shown that contaminant concentrations in some marine plants and animals reflect concentrations in their environment. Scientists use this process (termed bio-accumulation) to assess marine contamination resulting from human activity (e.g., pipeline discharges, dumping from ships).

There are problems with using biota as bio-accumulators (bio-indicators). For example, tissues from individuals of a species exposed to the same contaminant concentration may contain different levels of contamination after the same exposure time. These deviations reflect individual differences in factors such as age, sex, size, and physiological and nutritional states. Also, various species show different contaminant concentrations following identical exposure; differences in elimination rates may partially account for this. These factors must be considered when planning a monitoring programme in order to control their effects on the precision of the analysis (by reducing the variances). Variance reduction is necessary in order to detect smaller differences in mean contaminant concentrations observed in monitoring programmes.

For proper sampling and sample preparation, refer to Reference Method No 6 “Guidelines for monitoring chemical contaminants in the sea using marine organisms” and Reference Method No 12 Rev.2 “ Sampling of selected marine organisms and sample preparation for the analysis of chlorinated hydrocarbons”.

5.2. Cleaning of extraction thimbles

As for extraction of sediment samples, thimbles should be extracted first with the same solvent used for the extraction of the sample. As the extraction of biota sample is achieved with hexane, a pre-extraction of these thimbles is made with 250 ml of hexane for 8 hours in the Soxhlet apparatus, cycling the solvent through at a rate of 4 to 5 cycles per hour. Add into the solvent a few carborundum boiling chips to get a regular ebullition.

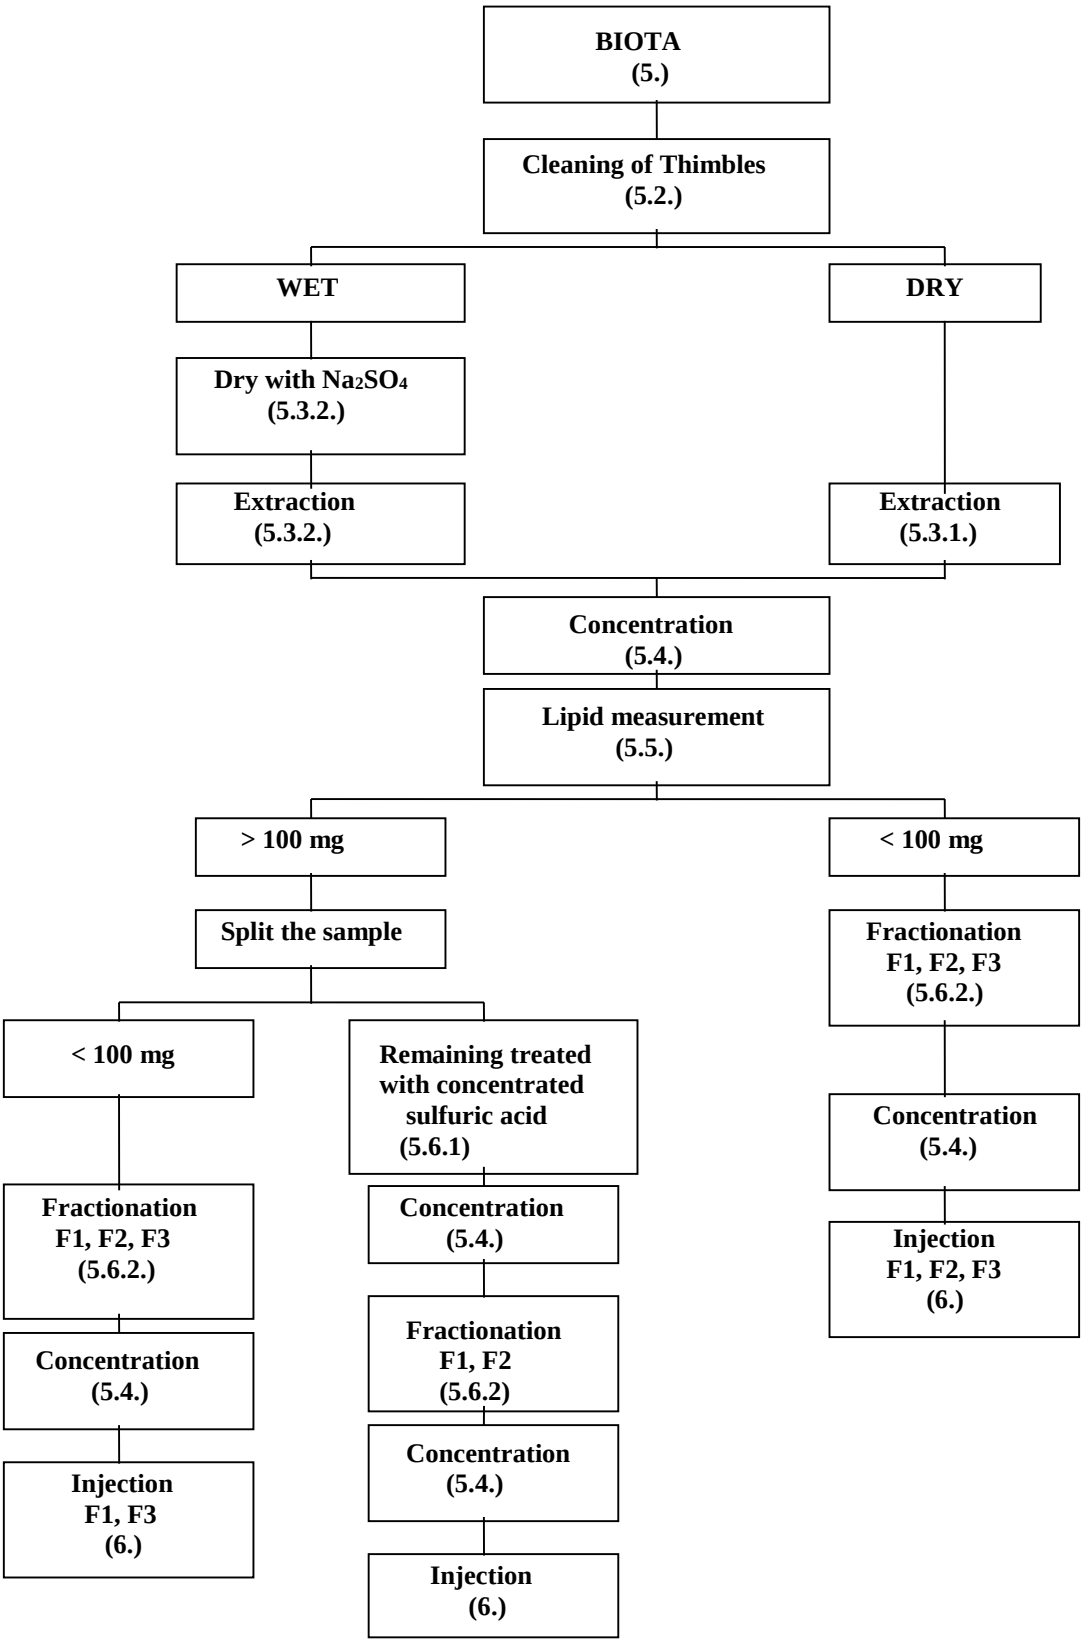


Figure 3: Diagram of the extraction procedure for biota samples.

5.3. Extraction of tissues

5.3.1. Extraction procedure for freeze-dried samples.

Take a 50 to 100 g fresh weight sub-sample from the sample. Weigh this sub-sample and freeze-dry it. When the sub-sample appears to be dry, re-weigh it and freeze-dry it for a further 24 hours and then re-weigh it. If the difference between the two dry weights is greater than 5%, continue the freeze-drying process. Special care must be taken to ensure that the freeze-drier is clean and does not contaminate the samples. The freeze drying procedure should be tested by drying 100 g Na_2SO_4 as a blank and extracting this as a sample. Pulverise the freeze-dried sub-sample carefully using a cleaned pestle and mortar. Accurately weigh about 5 to 10 g of this pulverised material, note the exact weight to be extracted, and place it into a pre-cleaned extraction thimble in a Soxhlet apparatus. The size of the sub-sample should be adjusted so that about 100 mg of extractable organic matter ("lipid") will be obtained. Smaller sub-samples should be used if residue concentrations are expected to be high. Add a known amount of internal standard to the sub-sample in the thimble before Soxhlet extraction. It is important to spike the sample at levels that are near to that of the analyte concentrations in the samples. If, in the end, the analyte and the internal standard concentrations do not fall within the established calibration range of the GC-ECD, the analysis must be repeated. Consequently, it may be advisable to perform range-finding analysis for samples of unknown character beforehand. Candidate internal standards are the same as for sediment samples (see 5.3.). Add about 200 ml of hexane or petroleum ether to the extraction flask with a few carborundum boiling chips, and extract the sample for 8 hours cycling the solvent through at a rate of 4 to 5 cycles per hour. Extract an empty thimble as a procedural blank, making sure to spike it with internal standards in the same fashion as the sample. If unacceptable procedural blanks are found, the source of contamination must be identified and eliminated rather than subtracting high blank values from the analytical results.

5.3.2. Extraction procedure without freeze-drying

Select a 25 to 100 g fresh weight sub-sample and place in a blender. Add anhydrous sodium sulphate to the sample, manually homogenise and determine whether the sample is adequately dried. If not, more sodium sulphate should be added until a dry mixture is obtained. Normally, 3 times by the sample weight used should be enough. Once this has been achieved, blend the mixture at high speed for 1 or 2 minutes until the mixture is well homogenised and the sample appears to be dry. Transfer the mixture to a pre-cleaned extraction thimble, add internal standards as described above and extract the dehydrated tissue with about 200 ml hexane or petroleum ether for 8 hours in a Soxhlet apparatus, cycling 4 to 5 times per hour. Extract the same amount of sodium sulphate as the procedural blank, making sure to add internal standards in the same fashion as the sample.

5.4. Concentration of the extract

Refer to section (4.4.)

5.5. Extractable Organic Matter (EOM)

Refer to section (4.5.)

5.6. Clean-up procedure and fractionation

5.6.1. Removal of lipids by concentrated sulphuric acid

If the lipid content of the extracts is higher than 100-150 mg, a preliminary step for the removal of the lipids is necessary before further sample purification. This can be carried out by using concentrated sulphuric acid. Treatment with sulphuric acid is used when chlorinated hydrocarbons are to be determined. However, sulphuric acid will destroy dieldrin and endrin so that an aliquot of the untreated extract must be set aside for the determination of these compounds.
CAUTION: During all this procedure it is very important to wear safety glasses.

Take an aliquot of the concentrated extract, containing about 200 mg of "lipids", transfer into a separatory funnel and add to this extract enough hexane in order to dilute the sample (40 to 50 ml should be enough), this will allow recovery of the hexane after acid treatment, because if the sample is too concentrated, the destroyed "lipids" will become almost solid and it will be difficult then to recover the hexane from this solid mass. Add 5 ml concentrated sulphuric acid to the extract and tightly fit the glass stopper and shake vigorously. Invert the funnel and carefully vent the vapours out through the stopcock. Repeat this procedure for several minutes. Place the separatory funnel in a rack and allow the phases to separate. Four or five samples and a spiked blank are convenient to process at one time. The extract should be colourless. Recover the hexane phase into a glass beaker. Dry with sodium sulphate and transfer the hexane into a Kuderna-Danish concentrator. Reduce the volume of the extract by evaporating the solvent with a gentle stream of pure nitrogen to about 1 ml.

5.6.2. Fractionation

Refer to section (4.6.2.)

6. CAPILLARY GAS CHROMATOGRAPHIC DETERMINATIONS

6.1. Gas chromatographic conditions

- Gas chromatograph with a split/splitless injection system, separate regulation system for inlet and column pressures and temperatures; multi-ramp temperature programming facilities (preferably microprocessor controlled), electron capture detector interfaced with the column with electronic control unit and pulsed mode facilities. An integrator with a short response time (0.25 s) is essential.

- Narrow-bore (0.22 mm internal diameter), 25 m long, fused silica open tubular column, coated with SE-54 (0.17 µm film thickness, preferably chemically bonded) with sufficient resolution to separate the relevant peaks in the standards provided for PCB analysis.

- Carrier gas should be high purity H_2. If this is not available or if the GC is not equipped with a special security system for hydrogen leak, He may be used. Gas purification traps should be used with molecular sieves to remove oxygen, moisture and other interfering substances.

- High purity nitrogen gas (99.995 %) as ECD make-up gas can be used (Argon/methane high purity gas is another option).

Conditions:

- H_2 or He carrier gas at inlet pressure of 0.5 to 1 Kg/cm^2 to achieve a flow rate of 1 to 2 ml/min.

- Make-up gas N_2 or Ar/CH_4 at the flow rate recommended by the manufacturer (between 30 and 60 ml/min.).

- ECD temperature: 300°C

6.2. Column preparation

Fused silica columns are the columns of choice for their inertness and durability (they are extremely flexible). They are made of material that is stable up to 360 °C. The 5 % phenyl methyl silicone gum (SE-54) liquid phase, is present as a thin, (0.17 µm), uniform film which can tolerate temperatures up to 300 °C. SE-54 is relatively resistant to the detrimental effects of solvents, oxygen and water, at least at low temperatures. These columns are even more resistant and durable if the liquid phase is chemically bonded to the support by the manufacturer.

For GC/MS work, it is advised to restrict the film thickness to 0.17 µm because with thicker films some of the phase could be released, resulting in an increase of the noise signal in the GC/MS.

The flexible fused silica columns can be conveniently connected directly to the inlet and outlet systems without the transfer lines used in conventional glass capillary chromatography which often lead to increased dead volume. Low bleed graphite or vespel ferrules provide a good seal.

The presence of extraneous peaks and elevated baseline drift will result in poor detector performance. This can be caused by components which elute from the column, such as residual solvents and low molecular weight liquid phase fractions on new columns and build-up of later eluting compounds on old columns. Conditioning is a necessary step to remove these contaminants. New columns are connected to the inlet (while left unconnected to the detector). Columns are flushed with carrier gas at low temperature for 15 min. to remove the oxygen, then heated at 70-100 °C for 30 min. and finally at 170 °C overnight. The column can be then connected to the detector. Old columns can be heated directly to elevated temperatures overnight. The final temperature is selected as a compromise between time required to develop a stable baseline and expected column life. Thus, it may be necessary for older columns to be heated to the maximum temperature of the liquid phase resulting in shorter column life. The temperature of the ECD, when connected to the column, should always be at least 50 °C higher than the column, in order to avoid condensation of the material onto the detector foil. It is essential that carrier gas flows through the column at all times when at elevated temperatures. Even short exposure of the column to higher temperature without sufficient flow will ruin the column.

CAUTION: if H_2 is used as a carrier gas, position the column end outside of the oven to avoid explosion risk.

6.3. Column test

When the column has been connected to the detector, the carrier gas flow is set to 30 ml per minute for a column with 4 mm internal diameter. The column performance is then measured according to the criteria of the "number of theoretical plates" for a specific compound and can be achieved according to the following procedure.

- Set injector and detector temperatures at 200 and 300°C respectively and the column oven temperature at 180 °C.
- Inject pp' DDT standard and measure the retention time (Tr). Adjust the column temperature to get a pp' DDT retention time relative to Aldrin of 3.03.
- Measure the width of the pp' DDT peak at its half height ($b_{1/2}$), in minutes and the retention time (Tr) also in minutes.
- Calculate the number of theoretical plates using the formula:

$$N = 5.54\left(\frac{Tr}{b_{1/2}}\right)^2$$

- A parameter which is independent of the column length is the height equivalent to a theoretical plate (HETP):

$$HEPT = \frac{L}{N}$$

Where L is the column length. Adjust the flow rate of the carrier gas to obtain optimum performance. The HETP should be as low as possible (i.e. the number of theoretical plates should be as great as possible).

The column remains in optimum condition as long as the liquid phase exists as a thin, uniform film. The quality of the film at the inlet side may be degraded as a result of repeated splitless

injections. Decreased column quality may be remedied by the removal of the end of the column (10 to 20 cm) at the inlet side. Chemically bonded liquid phases require less maintenance.

6.4. Electron capture detector

High-energy electrons, emitted by a radioactive source within the detector (e.g. a ^{63}Ni foil), are subject to repeated collisions with carrier gas molecules, producing secondary electrons. These electrons, upon returning to their normal state, can be captured by sample molecules, eluting from a GC column. The resulting reduction in cell current is the operating principle of an electron capture detector. The detector current produced is actually a non-linear function of the concentration of electron-capturing material. However, the useful linear range of an ECD may be greatly improved if the instrument is operated at a constant current, but in a pulsed mode, i.e. with short voltage pulses being applied to the cell electrodes. The current in the cell is kept constant by varying the frequency of the pulses.

Contamination of the detector (and thus lower sensitivity) may result from high-boiling organic compounds eluting from the column. Periodic heating to 350°C may overcome this problem. The ^{63}Ni ECD can be used at 320°C under normal operational conditions, in order to limit such contamination.

The optimum flow for an ECD (30 to 60 ml/min.) is much higher than carrier gas flow through the column of one or two ml/min. Thus an additional detector purge flow is necessary (N_2 or Ar/CH_4). Once leaving the outlet of the column, the compounds have to be taken up into an increased gas flow in order to avoid extra-volume band broadening within the detector. Thus, the detector purge flow also serves as the sweep gas.

6.5. Quantification

The most widely used information for identification of a peak is its retention time, or its relative retention time (i.e., the adjusted retention time relative to that of a selected reference compound). Retention behaviour is temperature dependent and comparison of retention times obtained at two or more temperatures may aid in determining a peak's identity. However, retention times are not specific and despite the high resolution offered by capillary columns, two compounds of interest in the same sample may have identical retention times.

One way of using retention indexes could be to inject di-n-alkyl-phthalates such as a mixture containing di-n-methyl-phthalate, di-n-ethyl-phthalate, di-n-propyl-phthalate, di-n-butyl-phthalate, di-n-hexyl-phthalate and di-n-heptyl-phthalate, which will cover the elution range from 70°C to 260°C. An arbitrary index of 100 is given to the di-n-methyl phthalate, 200 to the di-n-ethyl phthalate, and so on up to 700 to the di-n-heptyl phthalate; it is possible to identify all chlorinated pesticides by a proper retention index. This will be used also for unknown compounds which can be found easily on the GC/MS using the same index and so, identified. (Villeneuve J.P. 1986).

PCBs represent a complex mixture of compounds that cannot all be resolved on a packed column. Also there is no simple standard available for their quantification. Each peak in a sample chromatogram might correspond to a mixture of more than one individual compound. These difficulties have led to the recommendation of various quantification procedures. The usual method to quantify PCBs is to compare packed-column chromatograms of commercially available industrial formulations (Aroclors, Clophens, Phenoclors) with the sample chromatogram. Most commonly, it is possible to match one single formulation, such as Aroclor 1254 or Aroclor 1260 with the sample chromatogram. An industrial formulation (or mixture of formulations) should be chosen to be as close a match as possible and in the case of sample extracts from sediment or organisms, Aroclor 1254 and Aroclor 1260 are most frequently chosen.

For the second fraction obtained on Florisil separation, it is possible to quantify DDTs after comparison with the retention times of peaks in the sample chromatogram to those in the corresponding standard, the peak heights (or peak areas) are measured and related to the peak height (or peak area) in the standard according to the formula:

$$[\text{Concentration}] = \frac{h \times C \times V \times 1000}{h' \times V(\text{inj}) \times M \times R} \text{ ng/g (or pg/g)}$$

Where:

V = total extract volume (ml)
M = weight of sample extracted (g)
H = peak height of the compound in the sample
h' = peak height of the compound in the standard
C = quantity of standard injected (ng or pg)
V (inj) = volume of sample injected (µl)
R = Recovery of the sample

7. COMPUTERIZED GAS CHROMATOGRAPHY/MASS SPECTROMETRY (GC/MS)

7.1. Operating conditions

The chemical ionisation source of a mass spectrometer can be used to produce negative ions by electron capture reactions (CI-NI-MS) using a non-reactive enhancement gas such as methane or argon. CI-NI has the advantage of being highly selective, permitting the detection of specific compounds in complex matrices. Under CI-NI conditions, methane (99.99 %) is used as the reagent gas. Samples are introduced through a SE-54, 30 m x 0.25 mm i.d., fused silica column. The film thickness used is 0.17 µm in order to minimise the bleeding of the phase into the system. Helium is used as carrier gas with an inlet pressure of 13 psi, which gives a carrier flow of 1.5 ml/min. or a gas velocity of 44 cm/sec.

The temperature of the injection port is held at 250°C.

The temperature of the source is set at 240°C, the quadrupole at 100°C and the interface at 285°C.

Injections of 1-3 µl are made in the splitless mode.

The temperature programme of the oven starts at 70°C, for 2 minutes, then it is increased at 3°C/min. to 260°C and kept under isothermal conditions for 40 minutes.

8. NOTES ON WATER ANALYSIS

The levels of lipophilic compounds in tissues of aquatic organisms and organic fractions of sediments are determined to a large extent by the levels of these compounds in the surrounding water (marine mammals are an obvious exception). Data for CBs and hydrocarbons in sea water is therefore extremely useful for an understanding of the levels in organisms. However, the levels in sea water are extremely low and consequently, their determination needs considerable experience. Large volumes of water are required and extreme care has to be taken in order to avoid contamination during sampling, extraction and clean-up of the samples. Details are described in Manual and guide No 27 of IOC, 1993 and Villeneuve J.P. (1986).

9. ALTERNATIVE PROCEDURES

9.1. Combining sample preparation and extraction for chlorinated and petroleum hydrocarbons in sediment samples.

In the event that analyses for petroleum hydrocarbons and chlorinated compounds (and/or sterols) are of interest, the following extraction procedure can be used. To the freeze-dried sample introduce internal standards for each compound class. The following are suggested: 1) aliphatic hydrocarbons: - n-C_{14} d_{30}, n-C_{19} d_{40}, n-C_{32} d_{66}, 2) polycyclic aromatic hydrocarbons: Naphthalene d_8,

Hexamethylbenzene, Cadalene (deuterated PAHs are also useful), 3) organochlorine compounds: PCB congeners 29, 30, 121 or 198, ε HCH and Endosulfan Id_4, 4) sterols: 5 α (H)-androstan-3β-ol. These standards are used for quantifying the recovery of the total procedure. Samples are Soxhlet extracted for 8 hours with 250 ml of a mixture hexane / dichloromethane (50:50), cycling the solvent through at a rate of 4 to 5 cycles per hour. The solvent extract is concentrated by rotary evaporation down to 15 ml and transferred to a Kuderna-Danish tube. It is then further concentrated down to 5-6 ml under nitrogen gas. Following removal of sulphur and water, the extract is separated into aliquots: 1/3 for petroleum hydrocarbons and sterols and 2/3 for chlorinated hydrocarbons.

Note: Mercury method should be used only if chlorinated pesticides and PCBs are analysed. If the combined method is used for petroleum and chlorinated hydrocarbons, then the copper method should be used instead of mercury that will destroy some of the PAHs.

9.2. Supercritical fluid extraction (SFE) of marine samples

Sample preparation is probably the most time-consuming and labor-intensive analytical task performed in a laboratory. Studies shows that 60 % of the overall sample analysis time is spent in sample preparation which is the main source of error and of contamination. In addition, the amount of hazardous chemicals used for sample preparation is a continuous source of concern. Due to safe handling and disposal requirements, the reduction of their use is a priority for laboratories worldwide.

Supercritical fluids are gases (i.e. N_2O and CO_2) at room temperature and pressures above the critical point. The SFE technique allows an efficient extraction of a variety of contaminants with considerable reduction in the analysis cost, sample amount and allows the extraction of the thermal sensitive substances, reducing the amount of environmentally hazardous solvents.

A small change in the pressure of a supercritical fluid results in a big change in its density and the solvent strength of the fluid changes with changing density. As a result, one supercritical fluid easily performs the work of many solvents. If this is not enough, it is possible to add a modifier, such as methanol (a few per cent) to increase the solvating range of the fluid. Therefore, SFE should speed up the sample preparation process, minimising the wastes associated with the analysis.

Until now, the main fields of analytical applications of SFE are related to environmental studies and to the food-processing industry (Hawthorne, 1990, Bayona, 1993). A method using carbon dioxide (80°C-340 atm) for the extraction of total petroleum hydrocarbons has been approved as an EPA standard method. The extraction efficiency of modified CO_2 for the recovery of 41 organochlorine and 47 organophosphorus pesticides spiked on sand at different pressures and temperatures were higher than 80%. Furthermore, by increasing the extraction temperature up to 200°C, PCBs and PAHs can be extracted from naturally occurring samples with neat CO_2. Nam *et al.* (1991), have developed a method for rapid determination of polychlorinated organics in complex matrices. The method is based on direct coupling of supercritical fluid extraction with tandem supercritical fluid chromatography and gas chromatography. The on-line system permits simultaneous extraction and analysis with high reproducibility and accuracy.

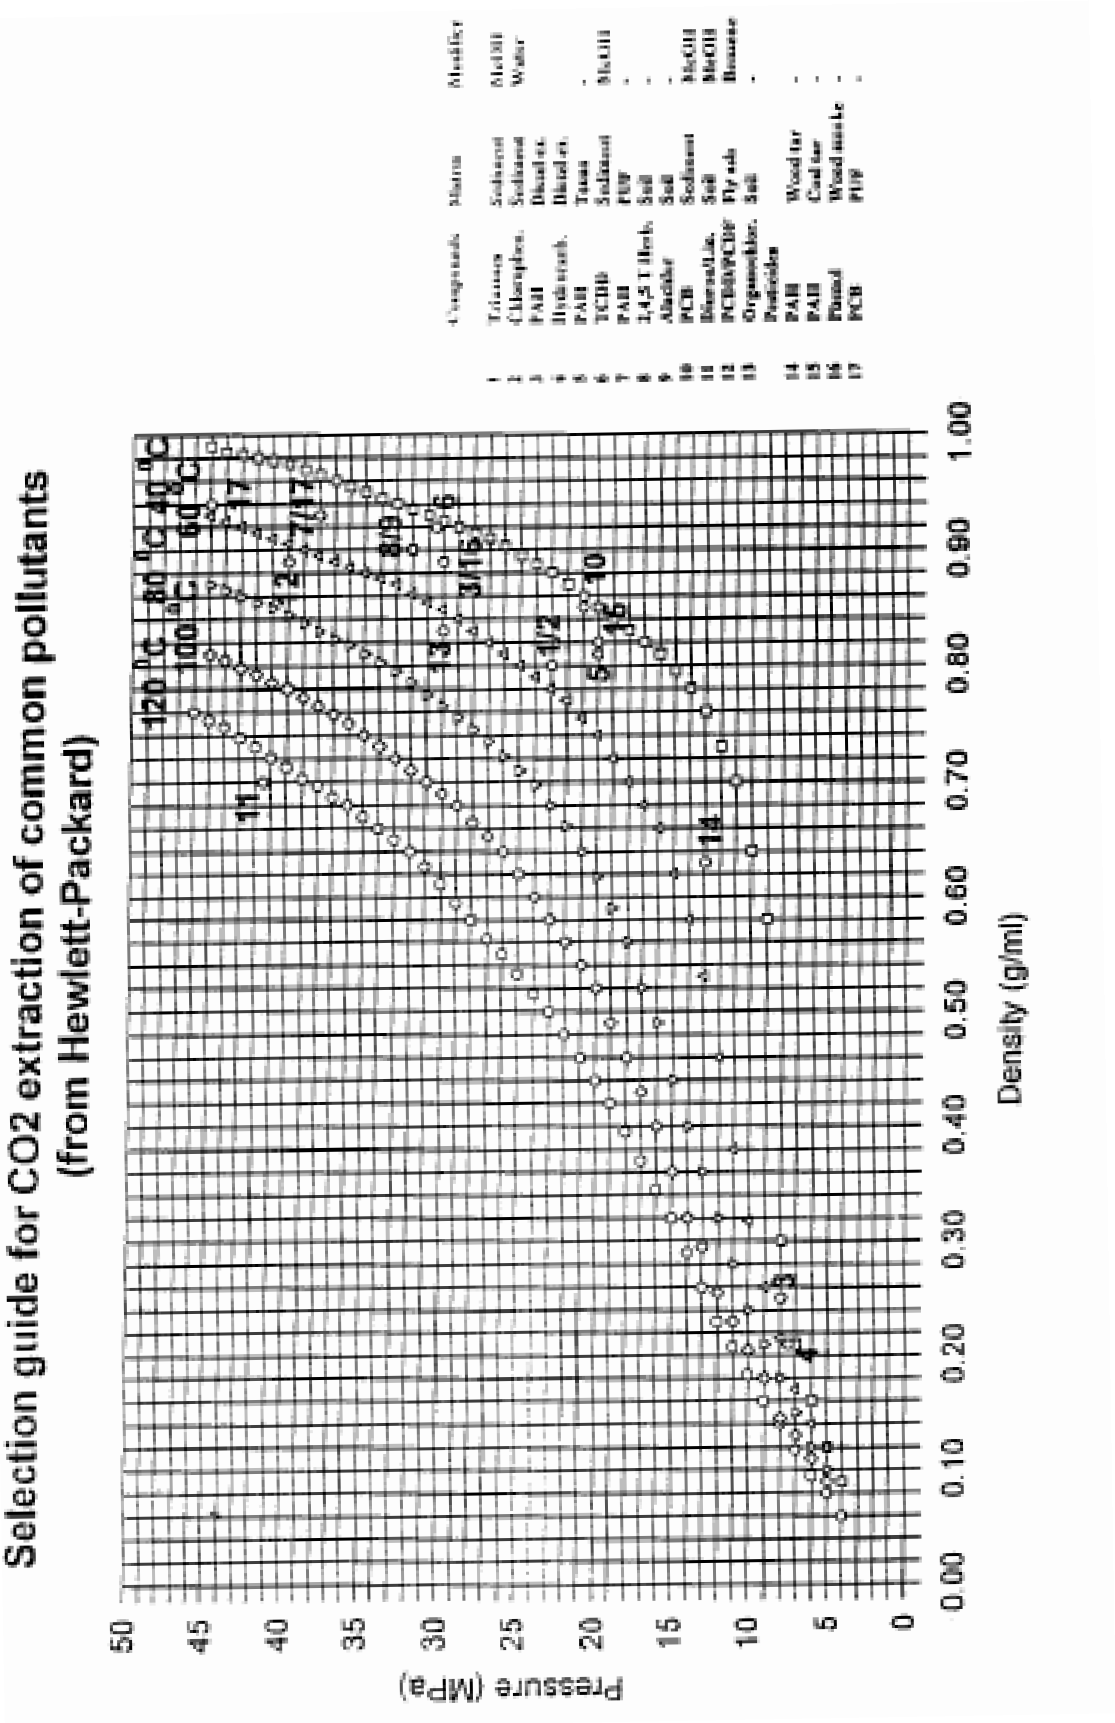

Figure 8: Guide for CO_2 extractions

9.3. Microwave assisted extraction for marine samples

9.3.1 Sediment

Another alternative method for the extraction of chlorinated hydrocarbons in sediment samples (or combined extraction for chlorinated hydrocarbons and petroleum hydrocarbons) is the use of the Microwave oven instead of the Soxhlet extractor. The main advantage of the microwave oven is the fact that, for one sample, only 40 ml of solvent mixture are used instead of 250 ml for clean-up of extraction thimbles and 250 ml for the extraction itself.

10 to 15 grams of freeze-dried sediment sample, ground and sieved at 250 µm, are put in the glass tube of the reactor. Appropriate internal standards (for OCs and/or PHs, see10.1.) are added to the sample for recovery and samples are extracted with 40 ml of a mixture of hexane / dichloromethane (50:50).

Extraction is realised within the following cycle:

- Power of the microwaves: 1200 watts
- Temperature increase to 115 °C in 10 minutes.
- Extraction maintained at 115 °C for 30 minutes
- Cooling to ambient temperature within one hour.

The carrousel containing 14 reactors, 12 samples could be extracted together with one blank and one Reference Material within 1 and half hour and with 10 times less solvent mixture than the standard Soxhlet extraction.

After cooling down to room temperature the solvent mixture is recovered in a 100 ml glass flask. The sediment is poured in a glass funnel containing a plug made of glass wool. The extracted sediment is washed with 10 - 20 ml of hexane. The extract follows then the procedure of clean-up and fractionation.

9.3.2 Biota

3 to 8 grams of freeze-dried biota sample is accurately weighted, the weight to be extracted is noted, and it is placed into the pre-cleaned glass tube of the reactor. A known amount of internal standard is added to the sub-sample in the tube before extraction. Candidate internal standards are the same than for sediment samples refers to section (5.3.1.)

Extraction is realized with 30 ml of a mixture hexane / acetone (90:10) within the following cycle:

- Power of the microwaves: 1200 watts
- Temperature increase to 115 °C in 10 minutes.
- Extraction maintained at 115 °C for 20 minutes
- Cooling to ambient temperature within one hour.

The carrousel containing 14 reactors, 12 samples could be extracted with one blank and one Reference Material within 1 and half hour and with 10 times less solvent mixture than the standard Soxhlet extraction.

After cooling down to room temperature the solvent mixture is recovered in a 100 ml glass flask. The powder of biota is poured in a glass funnel containing a plug made of glass wool. The extracted biota is washed with 10 - 20 ml of hexane. The extract is then concentrated with rotary evaporator and ready for E.O.M, clean-up and fractionation procedure.

10. DATA INTERPRETATION

10.1. DDT

The residence time of total DDT in the environment is relatively short (t1/2 = 3-5 years), so, at least 75-80 % of the current total DDT should be in the form of DDE or DDD if it was introduced into the environment before the 1975 ban. Values of Henry's law constant indicate that these compounds can reach the troposphere as vapour. These vapours are little adsorbed by airborne particulate matter and represent the major component in atmospheric chlorinated hydrocarbon levels. Vapour movements of these pollutants suggest that restrictions and regulations operating in the more technically advanced countries could only be partially effective on a worldwide basis.

The presence of the op DDT together with anomalous pp' DDT values in environmental samples indicates a recent treatment with this insecticide.

10.2. PCBs congeners

Among the 209 possible PCB congeners, seven of them: 28, 52, 101, 118, 138, 153 and 180, were selected as the most relevant because of their distribution in the chromatogram and in the chlorination range.

Recently, attention has been paid to congeners having 2 para-chlorines and at least 1 meta-chlorine. These congeners are called "coplanar" PCBs. Among the 209 congeners, 20 members attain coplanarity due to non-ortho chlorine substitution in the biphenyl ring. Three of these show the same range of toxicity as the 2,3,7,8 tetrachlorodibenzo-p-dioxin and the 2,3,7,8 tetrachlorodibenzofuran, these are the IUPAC Nº: 77, 126 and 169. These compounds should be identified and quantified in the environmental samples with high priority. They can be separated using fractionation with carbon chromatography (Tanabe *et al*., 1986).

10.3. Typical profiles of commercial mixtures

Formulations available in different countries are slightly different in their composition (Aroclor in USA, Kanechlor in Japan, Clophen in Germany, Phenoclor in France, Fenclor in Italy or Sovol in Russia). For the same global composition, such as Aroclor 1254, KC-500 or Phenoclor DP-5, the composition of individual congeners differs by 5-10 %. If a sample is collected on the French coast (therefore, contaminated with DP-5), and is quantified with DP-5 and Aroclor 1254, the difference observed in concentration could be in the order of 5-10 %. This shows the importance of choosing one common standard for the quantification of global industrial formulations or the importance of quantifying with individual congeners.

Percent contribution of individual chlorobiphenyls to Clophen A 50 and Aroclor 1254.

11. QUALITY ASSURANCE / QUALITY CONTROL

Guidelines on the QA/QC requirements for analysis of sediments and marine organisms are detailed in Reference Method No 57, "Contaminant monitoring programs using marine organisms: Quality assurance and good laboratory practice". Brief descriptions of issues that must be addressed in the course of understanding the procedures described here are given below.

11.1. Precision

The precision of the method should be established by replicate analysis of samples of the appropriate matrix. Estimate the precision of the entire analytical procedure by extracting five sub-samples from the same sample after homogenisation. Alternatively, perform replicate analysis of an appropriate certified reference material (RM; see below) containing the analytes of interest. The principal advantage of using a RM is that the material permits the simultaneous evaluation of accuracy while offering a well homogenised sample. Precision should be evaluated as a matter of course during the initial implementation procedure just before initiation of sample analysis.

11.2. Accuracy

The accuracy of the methods described here must be confirmed by analysis of a suitable RM (i.e. appropriate matrix, analytes) prior to initiation of sample analysis. Agreement between measured and certified concentrations for any individual analyte should be within 35 % and on average within 25%. It is advisable to introduce RMs on a regular basis (e.g. every 10-20 samples) as a method of checking the procedure. Further description of the preparation of control charts and criteria for data acceptance are discussed in Reference Method Nº 57.

11.3. Blanks

Blanks represent an opportunity to evaluate and monitor the potential introduction of contaminants into samples during processing. Contributions to the analyte signal can arise from contaminants in the reagents, those arising from passive contact between the sample and the environment (e.g. the atmosphere) and those introduced during sample handling by hands, implements or glassware. It is essential to establish a consistently low (i.e. with respect to analytes) blank prior to initiating analysis or even the determination of the method detection limit. In addition, it is necessary to perform blank determinations on a regular basis (e.g. every batch of samples).

11.4. Recovery

Recovery reflects the ability of the analyst to fully recover surrogate compounds introduced to the sample matrix or blank at the beginning of the procedure. The primary criteria for selection of compounds to be used for testing recovery are that they: 1) have physical (i.e. chromatographic/partitioning) properties similar to and if necessary spanning those of the analytes of interest, 2) do not suffer from interferences during gas chromatographic analysis, 3) are baseline resolved from the analytes of interest.

Recovery should be tested on all samples and blanks as a routine matter of course. Recoveries below 70% are to be considered unacceptable. Recoveries in excess of 100 % may indicate the presence of interference.

11.5. Archiving and reporting of results

Every sample should have an associated worksheet which follows the samples and the extracts through the various stages of the procedure and upon which the analyst notes all relevant details. An example of such a worksheet is given below. Each laboratory should construct and complete such a worksheet. Relevant chromatograms should be attached to the worksheet. Analyses should be grouped

and composite or summary analysis sheets archived with each group. Final disposal of the data will depend on the reasons for which it was collected but should follow the overall plan model.

All processed samples should be archived at all steps of the procedure:

- deep frozen (in the deep-freezer as it was received).
- freeze-dried (in sealed glass container kept in a dark place).
- extracted (after injection on the GC, sample extracts should be concentrated down to 1 ml and transferred into sealed glass vials, a Pasteur pipette sealed with a butane burner is adequate and cheap).

Sample: IAEA-357 : Marine Sediment

wet wt.
-------- = ..., % water in freeze dried sample determined by drying at 105°C : .....
dry wt.

.....g freeze-dried wt. extracted with hexane in Soxhlet extractor for 8 hours.

.....pg PCB Nº29, ...pg PCB Nº198, ...pg ε HCH and ….. pg Endosulfan Id_4 were added as internal standard.

The .....ml extract was reduced by rotary evaporator to approximately .....ml.

This was treated with sodium sulfate to dry the extract. Then treated with mercury to remove sulphur. This was further reduced to .....ml for lipid determinations. Corrected dry wt. : .....g.

Lipid determinations:

.....ml total extract;

10 µl aliquots weighed on micro-balance: .....mg; .....mg; .....mg.

HEOM = ...mg/g dry weight.

.....mg lipid subjected to column chromatography fractionation on Florisil.

F1: .....ml hexane

F2: .....ml hexane/dichloromethane (70:30)

F3: .....ml dichloromethane

GC determinations:

PCB Nº29 : .....ng recovered in F1 : .....% Recovery.

PCB Nº198 : .....ng recovered in F1 : .....% Recovery.

ε HCH : .....ng recovered in F2 : .....% Recovery.

Endosulfan Id_4: .....ng recovered in F3 : .....% Recovery.

Attach tabulation of individual compounds quantified in sample.

Sample worksheet for analysis of chlorinated compounds in marine sediments.

ANNEX

PREPARATION OF THE SOLUTION OF INTERNAL STANDARDS: PCB No 29, PCB No 198, ε HCH and Endosulfan I d4

Stock Solution of PCB No 29:

1 ml from the original vial (250ng/µl) should be transferred into a 100 ml volumetric flask, and then the volume is adjusted to 100 ml with hexane. This stock solution contains:

2.5 ng/µl of PCB No 29

Stock Solution of Endosulfan I d4:

1 ml from the original vial (250ng/µl) should be transferred into a 100 ml volumetric flask, and then the volume is adjusted to 100 ml with hexane. This stock solution contains:

2.5 ng/µl of Endosulfan I d_4

Working solution of internal standards:

0.5 ml from the stock solution of PCB No 29 (2.5 ng/µl) should be transferred into a 50 ml volumetric flask, then, 0.5 ml from the stock solution of Endosulfan I d4 (2.5 ng/µl) should be transferred into the volumetric flask, then 1 ml from the original vial (1ng/µl) of ε HCH should be transferred into that volumetric flask, then 0.5 ml from the concentrated solution (2ng/µl) of PCB No 198, and the volume adjusted to 50 ml with hexane. This working solution contains:

25 pg/µl of PCB No 29
20 pg/µl of PCB No 198
20 pg/µl of ε HCH
25 pg/µl of Endosulfan I d4

CAUTION: VIALS SHOULD BE COOLED AT 20°C PRIOR TO OPENING

Preparation of the Aroclor 1254 solution

Preparation of the stock solution:

1 ml from the original vial should be transferred into a 100 ml volumetric flask, then, the volume is adjusted to 100 ml with hexane. This stock solution contains:

6.5 ng/µl of Aroclor 1254

Preparation of the working solution:

1 ml from this stock solution should be transferred into a 50 ml volumetric flask and the volume adjusted to 50 ml with hexane. This working solution contains :

0.13 ng/µl of Aroclor 1254

CAUTION : VIAL SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of the Aroclor 1260 solution

Preparation of the stock solution:

1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5.44 ng/µl of Aroclor 1260

Preparation of the working solution:

1 ml from the stock solution should be transferred into a 50 ml volumetric flask, then the volume is adjusted to 50 ml with hexane. This working solution contains

0.1088 ng/µl of Aroclor 1260

CAUTION: VIAL SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of the pp' DDE, pp' DDD and pp' DDT solution

pp' DDE:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This stock solution contains:

5 ng/µl of pp' DDE

pp' DDD:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of pp' DDD

pp' DDT:

Stock solution: 1 ml of the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This stock solution contains:

5 ng/µl of pp' DDT

Working solution: pp' DDE, pp' DDD and pp' DDT together.

1 ml from the stock solution of pp' DDE, 2 ml of the stock solution of pp' DDD and 3 ml of the stock solution of pp' DDT should be transferred into a 100 ml volumetric flask and the volume adjusted to 100 ml with hexane. This solution contains

- pp' DDE : 50 pg/µl
- pp' DDD : 100 pg/µl
- pp' DDT : 150 pg/µl

NOTE: Further dilution may be necessary depending on the sensitivity of the EC Detector.

CAUTION: VIAL SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of Aldrin, Diedrin and Endrin standard solutions:

Aldrin:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of Aldrin

Dieldrin:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of Dieldrin

Endrin:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of Endrin

Working solution: Aldrin, Dieldrin and Endrin together.

1 ml from the stock solution of Aldrin, 1 ml from the stock solution of Dieldrin and 1 ml from the stock solution of Endrin are transferred into a 100 ml volumetric flask and the volume is adjusted to 100 ml with hexane. This working solution contains:

Aldrin	:	50 pg/µl
Dieldrin	:	50 pg/µl
Endrin	:	50 pg/µl

NOTE: Further dilution may be necessary depending on the sensitivity of the detector.

CAUTION: VIALS SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of the HCB and Lindane standard solutions:

HCB:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of HCB

Lindane:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of lindane

Working solution:

1 ml from the stock solution of HCB and 1 ml from the stock solution of Lindane are transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

HCB	:	50 pg/µl
Lindane	:	50 pg/µl

NOTE: further dilution may be necessary depending on the sensitivity of the EC Detector.

CAUTION: VIALS SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of the PCB congeners solution

In a 100 ml volumetric flask, transfer 1 ml from the original vial. Adjust to 100 ml with hexane in order to obtain the working solution with the following concentrations:

CB Nº:	Compounds:	Concentrations (pg/µl)
8	2,4’	17.50
18	2,2’,5	12
31	2,4’,5	10.6
28	2,4,4’	4.6
52	2,2’,5,5’	8.6
49	2,2’,4,5’	12.1
44	2,2’,3,5’	10.7
66	2,3’,4,4’	5.5
95	2,2’,3,5’,6	5.7
101	2,2’,4,5,5’	9.3
110	2,3,3’,4’,6	11.1
149	2,2’,3,4’,5’,6	12.1
118	2,3’,4,4’,5	8.5
153	2,2’,4,4’,5,5’	8.4
138	2,2’,3,4,4’,5’	13.8
183	2,2’,3,4,4’,5’,6	10.3
174	2,2’,3,3’,4’,5,6’	9.4
177	2,2’,3,3’,4’,5,6	9.5
180	2,2’,3,4,4’,5,5’	16.3
170	2,2’,3,3’,4,4’,5	13.4
199	2,2’,3,3’,4,5,5’,6’	9.3
194	2,2’,3,3’,4,4’,5,5’	12.6

Separate into 10 volumetric flasks of 10 ml, seal with Teflon tape and keep in refrigerated place in order not to evaporate them.

Determination of chlorobiphenyls in sediments – analytical method

CEMP Guidelines for Monitoring Contaminants in Sediments

(OSPAR Agreement 2002-16)

Technical Annex 2: technical annex on the analysis of PCBs in sediments

Determination of chlorobiphenyls in sediments – analytical method

1. Introduction

This annex provides advice on (chlorinated biphenyl) CB analysis for all sediment fractions and suspended particulate matter (*e.g.* < 2mm fraction and < 20μm fraction). The guideline is an update of the earlier version (Smedes and de Boer, 1994 and 1997) taking into account evolutions in the field of analytical chemistry and also covering the determination of planar CBs. Basically, these consist of mono-*ortho* (CB105, CB114, CB118, CB123, CB156, CB157, CB167 and CB189) and non-*ortho* substituted CBs (CB81, CB77, CB126 and CB169). When reviewing the literature, it should be noted that planar, coplanar and dioxin-like CBs / PCBs are all equivalent terms. OSPAR SIME has advised that monitoring for planar CBs in sediments should only take place when the concentrations of marker (non-planar) CBs are e.g. 100 times higher than the Background Assessment Concentrations for those compounds.

The analysis of CBs in sediments generally involves extraction with organic solvents, clean-up (removal of sulphur and column fractionation), and gas chromatographic separation with electron-capture or mass spectrometric detection. All stages of the procedure are susceptible to insufficient recovery of analytes and/or contamination. Quality control procedures are recommended in order to check the method's performance. These guidelines are intended to encourage and assist analytical chemists to reconsider their methods and to improve their procedures and/or the associated quality control measures where necessary. Due to the low concentrations of, particularly, non-*ortho* substituted CBs in sediments compared to those of other CBs, their determination requires an additional separation and concentration step. Therefore, in the relevant sections a distinction will be made between the non-*ortho* substituted CBs and the others.

These guidelines can also be used for several other groups of organochlorine compounds, *e.g.* DDTs and their metabolites, chlorobenzenes and hexachlorocyclohexanes. Recoveries in the clean-up procedures must be checked carefully. In particular, treatment with H_2SO_4 results in a loss of some compounds (*e.g.* dieldrin and endosulfanes (de Boer and Wells, 1996). Also, the clean-up procedure with silver ions can result in low recoveries for some pesticides (*e.g.* hexachlorocyclohexanes).

These guidelines are not intended as a complete laboratory manual. If necessary, guidance should be sought from highly specialised research laboratories. Whichever analytical procedure is adopted, each laboratory must demonstrate the validity of each step in the procedure. In addition, the use of a

second (and different) method, carried out concurrently with the routine procedure is recommended for validation. Analyses must be carried out by experienced staff.

2. Sampling and storage

Plastic materials (except polyethylene or polytetrafluorethene) must not be used for sampling due to the possible adsorption of contaminants onto the container material. Samples should be stored in solvent washed aluminium cans or glass jars. Aluminium cans are preferred, as glass jars are more susceptible to breakage. Samples should be transported in closed containers; a temperature of 25°C should not be exceeded. If samples are not analysed within 48 h after sampling, they must be stored in the short term at 4°C. Storage over several months or longer should be limited to those samples which have been frozen (< -20°C) and dried samples.

3. Precautionary measures

Solvents, chemicals and adsorption materials must be free of CBs or other interfering compounds. If not they should be purified using appropriate methods. Solvents should be checked by concentrating the volume normally used in the procedure to 10% of the final volume and then determining the presence of CBs and other interfering compounds by GC analysis. If necessary, the solvents can be purified by re-distillation but this practice is not favoured by most analytical laboratories as they generally opt to buy high quality solvents directly. Chemicals and adsorption materials should be purified by extraction and/or heating. Glass fibre materials (e.g. Soxhlet thimbles and filter papers used in pressurised liquid extraction (PLE)) should be cleaned by solvent extraction or pre-baked at 450°C overnight. Alternatively, glass thimbles with a G1 glass filter at the bottom can be used. Generally, paper filters should be avoided and substituted by appropriate glass filters. As all super cleaned materials are prone to contamination (*e.g.* by the adsorption of CBs and other compounds from laboratory air), materials ready for use should be held in sealed containers and should not be stored for long periods. All containers, tools, glassware *etc.* which come into contact with the sample must be made of appropriate material and must have been thoroughly pre-cleaned. Glassware should be extensively washed with detergents, heated at > 250°C and rinsed immediately before use with organic solvents or mixtures such as hexane/acetone. In addition, all glassware should preferably be covered with aluminium foil and stored in cupboards to keep out any dust. Old and scratched glassware is more likely to cause blank problems because of the larger surface and therefore greater chance of adsorption. Furthermore, scratched glassware can be more difficult to clean. All glassware should be stored in clean cupboards, ensuring dust cannot enter (QUASIMEME, 2007)

4. Pre-treatment

Before taking a subsample for analysis, the samples should be sufficiently homogenised.

CBs can be extracted from wet or dried samples, although storage, homogenisation and extraction are much easier when the samples are dry. Drying the samples, however, may alter the concentrations *e.g.* by the loss of compounds through evaporation or by contamination (Smedes and de Boer, 1994 and 1997). Losses and contamination must be accounted for.

Chemical drying can be performed by grinding with Na_2SO_4 or $MgSO_4$ until the sample reaches a free-flowing consistency. It is essential that there are at least several hours between grinding and extraction to allow for complete dehydration of the sample; any residual water will decrease the extraction efficiency.

Freeze-drying is becoming a more popular technique, although its application should be carefully considered. Possible losses or contamination must be checked. Losses through evaporation are diminished by keeping the temperature in the evaporation chamber below 0°C. Contamination during freeze-drying is reduced by putting a lid, with a hole of about 3 mm in diameter, on the sample container.

5. Extraction

The target compounds must be extracted from the sediment with an organic solvent prior to analysis. Extraction methods do not differ for planar CBs but, because of the low concentrations, a substantially larger sample intake has to be considered. Generally, at least a 100 g sample of freeze-dried sediment is required.

5.1 Wet sediments

Wet sediments are extracted in a step-wise procedure by mixing them with organic solvents. Extraction is enhanced by shaking, Ultra Turrax mixing, ball mill tumbler or ultrasonic treatment. Water miscible solvents are used (especially in the first step) such as methanol, acetone, acetonitrile, *etc.* The extraction efficiency of the first step is low as there will be a considerable amount of water in the liquid phase at that stage. The extraction is continued with a mixture of polar and apolar solvents (*e.g.* acetone/hexane or methanol/dichloromethane). For adequate extraction of target compounds, wet sediments must be extracted with organic solvents at least three times. The contact time with the solvent should be sufficient to complete the desorption of the CBs from the sediment.

When using a Soxhlet, extraction of wet sediments should be done in two steps. A polar solvent, such as acetone, is first used to extract the water from the sediment and then the flask is replaced and the extraction continued with a polar/apolar mixture such as acetone/hexane.

In both cases water must be added to the combined extracts and the CBs must be extracted to an apolar solvent such as hexane.

5.2 Dry sediments

For dried sediments, Soxhlet extraction is the most frequently used technique. A mixture of a polar and an apolar solvent (*e.g.* acetone/hexane) is recommended for efficient extraction; a good choice is 25% acetone in hexane. A greater proportion of polar solvent increases the extraction efficiency, but the polar solvent must be removed prior to gas chromatographic analysis. Extraction can be carried out with a normal Soxhlet or a hot Soxhlet apparatus. A sufficient number of extraction cycles must be performed (ca. 8 h for the hot Soxhlet and ca. 12 to 24 h for normal Soxhlet extraction). The extraction efficiency must be checked for different types of sediments by a second extraction step. These extracts should be analysed separately.

Although the use of binary non-polar/polar solvent mixtures and Soxhlet is still the benchmark for CB extraction, there have been numerous attempts to find alternative procedures, which are less time-consuming, use less solvent and/or enable miniaturisation. Amongst these novel approaches are

pressurised liquid extraction (PLE) and related subcritical water extraction (SWE), microwave-assisted extraction (MAE), matrix solid-phase dispersion (MSPD), ultrasound extraction (US) and supercritical fluid extraction (SFE).

From among the techniques mentioned, PLE or Accelerated Solvent Extraction (ASE) has – so far – been most successful. Soxhlet methods are easily translated into PLE as the same solvent compositions can be used. The method further allows interesting modifications that include in-cell clean-up of samples by adding fat retainers, such as florisil or alumina, to the cell, and the use of a small carbon column in the extraction cell, which selectively adsorbs dioxin-like compounds (subsequently isolated by back-flushing with toluene) (Sporring *et al*., 2003). PLE and MAE have the shared advantage over SFE that they are matrix-independent, which facilitates method development and changing-over from the classical Soxhlet extraction. Recent years have also seen an increased use of ultrasound-based techniques for analytes isolation from solid samples. With most applications, extraction efficiency is fully satisfactory, and sonication time often is 30 min or less (Roose and Brinkman, 2005).

All the methods described above are in principle suitable for extracting CBs from sediments. However, Soxhlet extraction is still the reference for alternative approaches.

6. Clean-up

6.1 Removal of sulphur and sulphur-containing compounds

An aqueous saturated Na_2SO_3 solution is added to a hexane extract. In order to allow the transfer of the HSO_3^- ions to the organic phase, tetrabutylammonium salts (TBA) and *iso*-propanol are then added to the mixture. Water is subsequently added to remove the *iso*-propanol. The aqueous phase must then be quantitatively extracted with hexane (Jensen *et al*., 1977). If the extraction was performed by a polar solvent miscible with water, then a Na_2SO_3 solution can be added directly after extraction. If the extraction mixture also contains an apolar solvent, then depending on the ratio of the solvents, the addition of TBA and *iso*-propanol may or may not be necessary. Any excess Na_2SO_3 and reaction products can be removed by the addition of water and thus partitioning between apolar solvent and water.

Japenga *et al*. (1987) developed a column method for the removal of sulphur and sulphur-containing compounds. The column material is made by mixing an aqueous solution of Na_2SO_3 with Al_2O_3. Some NaOH is also added to improve the reaction with sulphur. Subsequently the material is dried under nitrogen until a level of deactivation equivalent to 10 % water is reached. Storage must be under nitrogen because sulphite in this form may easily be oxidised to sulphate. Eluting the extract (hexane) through a column filled with this material results in removal of the sulphur in combination with further clean-up of the sediment extract. The sulphur removal properties are somewhat difficult to control.

Mercury, activated copper powder, wire or gauze (Smedes and de Boer, 1994 and 1997; Wade and Cantillo, 1996) remove the sulphur directly from an organic solvent. Although mercury is appropriate for removing sulphur, it should be avoided for environmental reasons. Copper can be applied during or after Soxhlet extraction. Ultrasonic treatment might improve the removal of sulphur. If sulphur appears to be present in the final extract the amount of copper or mercury used was insufficient and the clean-up procedure must be repeated.

Silver ions strongly bind sulphur and sulphur compounds. Loaded onto silica, $AgNO_3$ is a very efficient sulphur removing agent. It can be prepared by mixing dissolved $AgNO_3$ with silica and subsequently drying under nitrogen. Compounds containing aromatic rings are strongly retained, but for CBs this retention is reduced, probably due to shielding of the rings by the chlorine atoms. Retained compounds can easily be eluted by using cyclohexene, or another solvent with double bonds, as a modifier (Eganhouse, 1986; Japenga *et al*., 1987).

Elemental sulphur is strongly retained on a polystyrene-divinylbenzene copolymer column as generally applied for gel permeation chromatography (GPC). In addition, GPC combines sulphur removal with a clean-up stage.

All these methods have advantages and disadvantages. For different samples, the use of multiple methods may sometimes prove necessary. Several of the methods leave some aromatic sulphur compounds in the extract. These compounds elute from the GC column at similar retention times to some of the lower-chlorinated CBs. The major part of these compounds can be removed by eluting an apolar extract over a column with silica loaded with concentrated H_2SO_4. Other interfering compounds (*e.g.* phthalates and fatty acid esters) are also removed by using this procedure.

6.2 Further clean-up

The extraction procedures above will result in the co-extraction of many compounds other than CBs. The extract may be coloured due to pigments extracted from sediment, and may also contain sulphur and sulphur-containing compounds, oil, PAHs and many other natural and anthropogenic compounds which will need to be removed from the extract. Different clean-up techniques may be used, either singly or in combination, and the choice will be influenced by the selectivity and sensitivity of the final measurement technique and also by the extraction method employed. Most CBs are stable under acid conditions; therefore treatment with sulphuric acid or acid impregnated silica columns may be used in the clean-up.

The most commonly used clean-up methods involve the use of alumina or silica adsorption chromatography, but gel permeation chromatography (GPC) is also employed.

As CBs are apolar, clean-up using normal-phase chromatography is the most appropriate technique for the separation from other compounds. Using an apolar solvent (*e.g.* hexane or *iso*-octane) as an eluent, CBs normally elute very rapidly. All polar solvents used in the extraction or sulphur removal step should be removed before further clean-up. The last concentration step is usually performed by evaporation with a gentle stream of nitrogen. Evaporation to dryness should always be avoided.

Deactivated Al_2O_3 (with 5-10% water) is often used as a primary clean-up method. Provided that sulphur has been removed beforehand, Al_2O_3 clean-up sometimes yields a sufficiently clean extract for a GC-ECD analysis of the sample to be performed. Al_2O_3 removes lipid compounds from the extracts (although samples with a very high lipid content and low CB concentrations may require additional clean-up).

Deactivated silica (with 1-5% water) does not retain CBs (including planar CBs) and only slightly retains polycyclic aromatic hydrocarbons (PAHs) when eluted with hexane or *iso*-octane. When organochlorine pesticides are also to be determined in the same extract, deactivation of the silica with a few percent of water is essential.

For high activity silica (overnight at 180°C) the retention of CBs is negligible, while PAHs are more strongly retained. The CBs and a few other organochlorine compounds are eluted with apolar solvents. More polar solvents (*e.g.* hexane/acetone) should be avoided as some interfering organochlorine pesticides would be eluted.

For the separation of CBs from lipids or oil components, reversed-phase HPLC can be used. In reversed-phase chromatography CBs elute during a solvent gradient of 80 to 90% methanol, together with numerous other compounds of similar polarity. Most of the above mentioned extraction methods and clean-up procedures yield an extract containing an apolar solvent. These cannot be injected directly for reversed-phase chromatography, and so compounds must be transferred between solvents several times *e.g.* before injection and after elution. When using polar solvents for extraction (*e.g.* for wet sediments) reversed-phase columns could be used directly for clean-up. When eluting an acetonitrile extract from a C_{18} solid phase extraction (SPE) column with acetonitrile, high molecular hydrocarbons are strongly retained while CBs elute in the first few column volumes.

The above mentioned normal-phase chromatographic procedures on silica and Al_2O_3 can be transferred to HPLC having the advantages of higher resolution and better reproducibility.

When using GPC the elution of CBs should be carefully checked. When applying GPC, two serial columns are often used for improved lipid separation. Solvent mixtures such as dichloromethane/hexane or cyclohexane/ethyl acetate can be used as eluents for GPC. However, a second clean-up step is often required to separate the CBs from other organohalogenated compounds.

One advantage of using PLE extraction is that it is possible to combine the clean up with the extraction, especially when mass spectrometry will be used as the detection method. If Soxhlet extraction is used for biota, then there is a much greater quantity of residual lipid to be removed than in the case of PLE with fat retainers. An additional clean-up stage may therefore be necessary. Methods have been developed for online clean-up and fractionation of dioxins, furans and CBs with PLE for food, feed and environmental samples (Sporring *et al*., 2003). The first method utilises a fat retainer for the on-line clean-up of fat. Silica impregnated with sulphuric acid, alumina and Florisil have all been used as fat retainers. A non-polar extraction solvent such as hexane should be used if fat retainers are used during PLE.

Non-*ortho* CBs require a more specialised clean-up, similar to that which is generally associated with the analysis of dioxins and furans. Although initial clean-up may very well proceed along the lines described above, the larger sample intake results in even larger amounts of co-extractives and care has to be taken that the capacity of the adsorption columns is not exceeded and/or that sulphur is adequately removed. Often, more rigorous procedures are applied to remove the excess material by e.g. shaking the sample with concentrated sulphuric acid. A more efficient and safer alternative is to elute the sample over a silica column impregnated with sulphuric acid (40 % w/w).

Non-*ortho* CBs are nearly always separated from the other CBs using advanced separation techniques. A very efficient method is to inject the extracts (after concentrating them) into a HPLC system coupled to PYE (2-(1-pyrenyl) ethyldimethylsilylated silica) column. Column dimensions are typically 4.6 x 150 mm column, but combinations of several columns in-line are sometimes used. PYE columns not only allow the separation of *ortho,* mono-*ortho* and non-*ortho* CBs on the basis of structural polarity from each other but also from dibenzo-*p*-dioxins and dibenzofurans. The eluting solvent is an apolar solvent

such as *iso*-hexane. When coupled to a fraction collector, the use of a HPLC system allows the automatic clean-up of a considerable number of samples. Alternatively, HPLC systems equipped with porous graphite carbon. Column sizes are in the order of 50 x 4.7 mm and care has to be taken that the column is not overloaded. Similarly to PYE columns, they will separate non-*ortho* CBs from the others and from dioxins and furans. Fully automated systems, such as Powerprep, that combine several steps are routinely used (Focant and De Pauw, 2002).

7. Pre-concentration

Evaporation of solvents with a rotary-film evaporator was up until recent the common method. However, evaporation of solvents using this technique should be performed at low temperature (water bath temperature of ≤ 30°C) and under controlled pressure conditions, in order to prevent losses of the more volatile CBs. To reduce the sample to the final volume, solvents can be removed by blowing-down with gently streaming nitrogen. Only nitrogen of a controlled high quality should be used. As a solvent for the final solution to be injected into the GC, *iso*-octane is recommended.

Turbovap sample concentrators can also be used to reduce solvent volume. This is a rapid technique, but needs to be carefully optimised and monitored to prevent both losses (both of volatiles and solvent aerosols) and cross-contamination. The use of rotary-film evaporators is more time consuming but more controllable. Here also, evaporation to dryness should be avoided at all costs. Syncore parallel evaporators (Buchi, Switzerland) can be used with careful optimisation of the evaporation parameters. The Buchi Syncore Analyst also uses glass tubes but the system is sealed, avoiding contamination from the lab air during evaporation. It does not use a nitrogen stream, thus reducing the loss of volatiles and if the flushback module is fitted the sides of the tubes are rinsed automatically thus reducing the loss of the heavier components. Again water-bath temperatures should be minimised to prevent losses. When reducing the sample to the required final volume, solvents can be removed by a stream of clean nitrogen gas. Suitable solvents for injection into the gas chromatograph (GC) include hexane, heptane, toluene and *iso*-octane.

7.1 Calibration and preparation of calibrant solutions

Internal standards (recovery and quantification standards) should be added in a fixed volume or weight to all standards and samples. The ideal internal standard is a CB which is not found in the samples. All CBs with a 2,4,6-substitution (e.g. CB115, CB155, CB198) are, in principle, suitable. Alternatively, 1,2,3,4-tetrachloronaphthalene or homologues of dichloroalkylbenzylether can be used. For GC analysis with mass selective detection (GC-MS), ^{13}C labelled CBs should be used for each degree of chlorination. This especially critical for the non-*ortho* CBs. If possible, the labelled calibrant solutions should correspond to the unlabelled determinants. For the non-*ortho* CBs a labelled standard is available for each congener and use of all of them is recommended. When preparing a calibration solution for a new determinant for the first time, two independent stock solutions of different concentrations should always be prepared simultaneously to allow cross checking. A new calibration solution should also be cross-checked to the old standard solution. Crystalline CBs of known purity should always be used for preparing calibration solutions. If the quality of the standard materials is not guaranteed (*e.g.* as in the case for a Certified Reference Material) by the producer or supplier, it should be checked by GC preferably with mass spectrometric detection. Solid standards should be weighed to a precision of 10^{-5} grams. In recent years, a lot of certified commercial custom made

standards have become available and laboratories have been switching to these. Calibration solutions should preferably be stored in ampoules in a cool and dark place. When stored in containers the weight loss during storage should be recorded.

8. Instrumental determination

8.1 Injection techniques

The two modes commonly used are splitless and on-column injection. In split injection, strong discrimination effects may occur. The liner should possess sufficient capacity with respect to the injected volume after evaporation, but should not be oversized to avoid poor transfer to the column and losses by adsorption. Liners with light packing of (silylated) glass wool may improve the performance for CBs, but may degrade some organochlorine compounds like DDT, which are often included in national monitoring programmes.

Recently, other techniques such as temperature-programmed or pressure-programmed injection have become more prominent. They offer additional advantages such as an increased injection volume without the negative effects previously associated with that, but should be thoroughly optimised before use. Increasing the injection volume will allow either or both the elimination of an extra evaporation step and lowering the detection limits.

8.2 Carrier gas

Hydrogen is the preferred carrier gas and is indispensable for columns with very small inner diameters. Helium is also acceptable and the standard carrier for GC-MS.

8.3 Columns

Only capillary columns should be used. The following parameters are recommended:

Minimum Length	50 m (for microcolumns of internal diameter <0.1 mm, shorter columns can be suitable).
Maximum internal diameter	0.25 mm. Note that for diameters <0.15 mm the elevated pressure of the carrier gas needs special instrumental equipment as most of the instruments are limited to 400 kPa.
Film thickness	0.2-0.4 µm.

Columns which do not fulfil these requirements generally do not offer sufficient resolution to separate CB28, CB105 and CB156 from closely eluting CBs. A wide range of stationary phases can be used for CB separation. The chemical composition is different for many producers and depends on the maximum temperature at which the column can be operated. Further advice may be found in the producer's catalogues, where compositions, applications and tables to compare products from different manufacturers are included.

In recent years, new chromatographic phases have become available that result in an improved separation of critical CB pairs. A good example is the HT-8 phase (1,7-dicarba-closo-dodecarborane phenylmethyl siloxane) (Larsen *et al*., 1995) that shows a remarkable selectivity for CBs. This column

is currently recommended for CB analysis. Examples of the retention times for various CBs are given in Table 1.

8.4 Detection

The electron capture detector (ECD) is still frequently used for CB analysis. Injection of chlorinated solvents or oxygen-containing solvents should therefore be avoided due to the generation of large interfering signals. When using mass selective detectors (MSD) negative chemical ionisation mode (NCI) is extremely sensitive for pentachlorinated to decachlorinated CBs and is approximately ten fold better than ECD. However, MS systems have improved considerable allowing analysis by Electron impact ionisation (EI), whereas before, electron-capture negative ion chemical ionisation (ECNICI) was often necessary in order to detect the low concentrations of, in particular the planar CBs. Suggested target and qualifier ions for *ortho* CBs (including non-*ortho* CBs) are shown in Table 1 and in Table 2 for non-*ortho* CBs.

Table 1 Example of retention times for selected CB congeners using a 50 m HT8 column (0.25 mm i.d. and 0.25 µm film), along with possible target and qualifier ions. Temperature programme: 80°C, hold for 1 minute, ramp 20°C/minute, to 170 °C, hold 7.5 minutes, ramp 3 °C/minute to 300 °C, hold for 10 minutes.

Next to conventional GC-MS, the use of ion-trap with its tandem MS² option – i.e., yielding improved selectivity – is receiving increased attention. The use of GC-ITMS provides a less expensive alternative to high-resolution mass spectrometry (HRMS), which is commonly used to determine PCDD/F and, as such, also ideally suited for all CB groups (Eppe *et al*., 2004).

Table 2 Possible target and qualifier ions for non-*ortho* CBs, including labelled internal standards

CB169	360	362	218	220

8.5 Separation, identification and quantification

When using GC-ECD and to a certain extent GC-MS, two columns with stationary phases of different polarity should be used, as column-specific coelution of the target CBs with other CBs or organochlorine compounds occurs. The temperature programme must be optimised for each column to achieve sufficient separation of the CB congeners to be determined. An isothermal period in the programme around 200-220°C of approximately 30 minutes is recommended. Care should be taken that CBs of interest do not co-elute with other CB congeners (for example CB28 and CB31). When using GC-ECD, compounds are identified by their retention time in relation to the standard solutions under the same conditions. Therefore GC conditions should be constant. Shifts in retention times

should be checked for different areas of the chromatogram by identifying characteristic, unmistakable peaks (*e.g.* originating from the internal standard or higher concentrated CBs such as CB153 and CB138. When using a GC-MS system, the molecular mass or characteristic mass fragments or the ratio of two ion masses can be used to confirm the identity of separated CBs. Since calibration curves of most CBs normally non-linear when using a GC-ECD, but should be linear for GC-MS, a multilevel calibration of at least five concentrations is recommended. The calibration curve must be controlled and the best fit must be applied for the relevant concentration range. Otherwise, one should strive to work in the linear range of the detector must. Analysis of the calibration solutions should be carried out in a mode encompassing the concentrations of the sample solutions (or alternatively by injecting matrix-containing sample solutions and matrix-free standard solutions distributed regularly over the series). When the chromatogram is processed with the help of automated integrators the baseline is not always set unambiguously and always needs to be inspected visually. When using GC-ECD, peak height is preferable to peak area for quantification purposes. From the two columns of different polarity the more reliable result should be reported.

Recent years have witnessed the emergence of so-called comprehensive two-dimensional gas chromatography (GC x GC) – a technique that can be used to considerably improve analyte/matrix as well as analyte/analyte separation. Briefly, a non-polar x (semi-)polar column combination is used, with a conventional 25-30 m long first-dimension, and a short, 0.5-1 m long, second-dimension column. The columns are connected via an interface called a modulator. The latter device serves to trap, and focus, each subsequent small effluent fraction from the first-dimension column and, then, to launch it into the second column. The main advantages of the comprehensive approach are that the entire sample (and not one or a few heart-cuts, as in conventional multidimensional GC (Dallüge *et al*. 2003) is subjected to a completely different separation, that the two-dimensional separation does not take any more time than the first-dimension run, and that the re-focusing in the modulator helps to increase analyte detectability. The most interesting additional benefit for CBs is, that structurally related as CB congeners show up as so-called ordered structures in the two-dimensional GC x GC plane. The very rapid second-dimension separation requires the use of detectors with sufficiently high data acquisition rates. Initially, only flame ionisation detectors could meet this requirement. However, today there is also a micro-ECD on the market that is widely used for GC x GC-µECD of halogenated compound classes. Even more importantly, analyte identification can be performed by using a time-of-flight mass spectrometer [Dallüge *et al*., 2002] or – with a modest loss of performance, but at a much lower price – one of the very recently introduced rapid-scanning quadrupole mass spectrometers [Korytar *et al*., 2005; Adachour *et al*., 2005). So far, the use of GC x GC has been limited to qualitative applications and still seems inappropriate for routine quantification of analytes.

9. Quality assurance

Planners of monitoring programmes must decide on the accuracy, precision, repeatability, and limits of detection and determination which they consider acceptable. The limit of determination should depend on the purpose of the investigation. A limit of at least 0.1 ng/g (dry weight, fraction < 2mm) should be reached, but detection limits of 0.01 ng/g are achievable nowadays. The method for calculating the limit of determination should reflect QUASIMEME advice (Topping *et al*., 1992). The limit of determination that can be achieved depends on the blank, on the sample matrix, on

concentrations of interfering compounds and on the mass of sediment taken for analysis. References of relevance to QA procedures include HELCOM, 1988; QUASIMEME 1992; Wells *et al*., 1992; Oehlenschläger, 1994; Smedes *et al.*, 1994 and ICES, 1996.

9.1 System performance

The performance of the GC system should be monitored by regularly checking the resolution of two closely eluting CBs. A decrease in resolution points to deteriorating GC conditions. The signal-to-noise ratio yields information on the condition of the detector. A dirty ECD detector or MS ion source can be recognised by the presence of an elevated background signal together with a reduced signal-to-noise ratio. Chromatograms should be inspected visually by a trained operator.

9.2 Recovery

The recovery should be checked and reported. One method is to add an internal (recovery) standard to each sample immediately before extraction and a second (quantification) standard immediately prior to injection. If smaller losses occur in extraction or clean-up or solutions are concentrated by uncontrolled evaporation of solvents (*e.g.* because vials are not perfectly capped) losses can be compensated for by normalisation. If major losses are recognised and the reasons are unknown, the results should not be reported, as recoveries are likely to be irreproducible. A control for the recovery standard is recommended by adding the calibration solution to a real sample. Recoveries should be between 70 and 120%, if not, samples should be repeated.

Guidelines on the determination of chlorinated hydrocarbons in sediment

Guidelines on the determination of chlorinated hydrocarbons in sediment

1. Introduction

These guidelines are based on the review from Smedes and de Boer (1994, 1998) and Eljarrat and Barceló (2009).

The analysis of chlorinated hydrocarbons in sediments generally involves extraction with organic solvents, clean-up, removal of sulphur, column fractionation and gas chromatographic separation, mostly with electron capture or mass-spectrometric detection.

All steps of the procedure are susceptible to insufficient recovery and contamination. Quality control measures are recommended in order to regularly monitor the performance of the method. These guidelines are intended to encourage and assist analytical chemists to critically review their methods and to improve their procedures and quality assurance measures, if necessary.

These guidelines can be applied for the determination of several types of chlorinated hydrocarbons, e.g., chlorinated biphenyls (CB), chlorobenzenes, DDT and its metabolites and hexachlorocyclohexanes. It should be noted that these guidelines do not cover the determination of non-*ortho* substituted CB. Due to the low concentrations of non-*ortho* CB in sediments comparing to those of other CB, their determination requires an additional separation and concentration step similar to the analysis of polychlorinated dibenzo-*p*-dioxins and dibenzofurans (PCDD/F).

These guidelines are not intended as complete laboratory manual. If necessary, guidance should be sought from specialized laboratories. Laboratories should demonstrate validity of each methodological step. Moreover, use of an alternative method, carried out concurrently to the routine procedure, is recommended for validation.

Contracting parties should follow the HELCOM monitoring guideline but minor deviations from this are acceptable if the method achieves comparable results. Validation of the adopted method needs to be performed on the relevant matrix and concentration range e.g. by taking part in intercomparison studies or proficiency testing schemes.

2. Sampling and storage

The major criterion for successful sediment sampling is to ensure undisturbed sample stratification. (For further details about sampling, see Annex B-13, Appendix 3 “Technical note on the determination of heavy metals in marine sediments” of the COMBINE manual.)

Plastic materials (except polytetra-fluorethene, PTFE) should not be used for sampling and storage due to the risk of adsorption of target compounds onto the container material. Samples should be transported in closed containers and preferentially at temperatures below 10 °C. The samples should be stored at 4 °C as soon as possible, but at least if they have not been analysed within 48 hours after collection (short-term storage). For long-term storage over several months the samples should be frozen below -20 °C or dried (Law and de Boer, 1995). When drying, avoid methods with substantial risk of losing volatile substances (see Chapter 4: Pretreatment).

3. Blanks and contamination

Basically, care should be taken to avoid contaminations during all steps of the analytical chain, including sampling, extraction and clean-up.

In order to reduce blank and sample contaminations to a minimum it is strongly recommended to pretreat all used glassware, solvents, chemicals, adsorption materials, etc., as follows:

- Glassware should be thoroughly washed with detergents and can be furthered cleaned, other than calibrated instruments, by heating at temperatures > 250 °C. The glassware should be rinsed with an organic solvent prior to use.

- All solvents should be analyzed for impurities by concentrating to 10 % of the regular final volume. This concentrate is then analysed similarly to a sample by HPLC or GC. The solvent blank should not contain target analytes or other interfering compounds in higher concentrations than specified by the laboratory.

- All chemicals and adsorption materials should be analyzed for impurities and purified (e.g., by heating or extraction), if necessary. Soxhlet thimbles should be pre-extracted. Glass fiber thimbles are preferred over paper thimbles. Alternatively, full glass Soxhlet thimbles, with a G1 glass filter at the bottom, can be used.

Storage of these supercleaned materials for a longer period is not recommended, as laboratory air might contain target compounds which can adsorb onto these materials. Therefore, contaminated blank samples might occur despite precautionary measures due to contamination from the air. Volatile compounds are usually the most common contaminants in blanksamples (Gremm and Frimmel, 1990). Therefore, if possible, critical steps should be done in a clean bench.

4. Pretreatment

The samples should be thoroughly homogenized before subsampling for analysis. The amount of samples usually depends on the expected concentrations. For the marine environment, the amount of sample should be equal to an amount representing 50–100 mg of organic carbon.

Chlorinated hydrocarbons can be extracted from wet or dried samples. However, storage, homogenization and extraction are easier to handle with dried samples.

Drying the samples at ambient or elevated temperatures as well as freeze-drying may alter the concentrations, e.g., by contamination or loss of compounds through evaporation (Law *et al.,* 1994). Therefore, potential losses and contaminations should be analyzed in advance, e.g. by exposing 1–2 g CIS-bonded silica to the drying conditions and subsequent extraction and analysis (clean-up can be omitted) (Smedes and de Boer, 1998). For evaluation of potential losses, analytes identical or similar to chlorinated hydrocarbons need to be added to the material. However, bear in mind that added analytes can behave differently from analytes that have interacted longer with the matrix material and therefore may be sorbed more strongly. To avoid contamination during freeze-drying, placing a lid with a hole of about 3 mm in diameter on the sample container is suggested.

Chemical drying of samples can be performed by grinding with Na_2SO_4, or $MgSO_4$ until the sample reaches a sandy consistency. It is essential that several hours elapse between grinding and extraction to allow for complete dehydration of the sample. Residual water will decrease extraction efficiency.

5. Extraction and clean-up

The target compounds must be extracted from the sediment with an organic solvent prior to further analysis.

Other extraction and clean-up methods than those described below may be used, provided that the methods have been tested and found equivalent to established methods regarding e.g. recovery.

5.1. Extraction of wet sediments

Wet sediments are extracted by mixing with organic solvents. Extraction is enhanced by shaking, ultra-turrax mixing, ball mill tumbler or ultrasonic treatment. Water-miscible solvents such as methanol, acetone, and acetonitrile, are used, in particular in the first step. The extraction efficiency of the first step is

low as there will be a considerable amount of water in the liquid phase. Extraction will be continued with a mixture of polar and apolar solvents such as acetone/ hexane or methanol/ dichloromethane. It has to be kept in mind that hexane and dichloromethane is a lot more toxic than similar solvents such as pentane, heptane, cyclohexane, isohexane. For complete extraction at least three subsequent extractions are required and a contact time of up to 24 hours with the solvent should be sufficient to complete the desorption of the chlorinated hydrocarbons from the sediment.

Soxhlet extraction or extraction by pressurized liquid extraction such as ASE of wet sediments should be conducted in two steps. First, a polar solvent, such as acetone, is used to extract the water from the sediment. In a second step the collecting flask is replaced and the extraction will be continued using a less polar solvent or solvent mixture such as acetone/hexane or toluene. Thereafter, the extracts will be combined.

To separate the water and keep the chlorinated hydrocarbons in a solvent that is compatible with the continued analysis different methods can be used. For example, water will be added to the combined extracts and the chlorinated hydrocarbon compounds will be extracted to a non-polar solvent. Another possibility is to add Na_2SO_4 to bind water.

Extraction should be conducted with a sufficient number of extraction cycles. Extraction efficiency should be analyzed for different types of sediments through a second extraction step. The extracts will be analysed separately and compared. A recovery of more than 90 % during the first extraction step is considered adequate.

5.2. Extraction of dry sediments

For dried sediments pressurized liquid extraction (e.g. ASE) is frequently applied to extract chlorinated hydrocarbons. The use of a mixture of a polar and a non-polar solvent, e.g., 25 % (v/v) acetone/hexane is recommended for sufficient extraction efficiency. A higher content of polar solvent increases extraction efficiency, but it has to be removed prior to gas chromatographic analysis.

Alternatively to ASE, extraction can be conducted with a regular Soxhlet, a hot Soxhlet with at least 50 to 60 extraction cycles (approximately 8 hours for the hot Soxhlet) or by microwave extraction. Supercritical fluid extractions have also been demonstrated, but have not found wide application due to low reproducibility compared to the other technique (Law et al, 2011).

Extraction should be conducted with a sufficient number of extraction cycles. Extraction efficiency should be analyzed for different types of sediments through a second extraction step. The extracts will be analysed separately and compared. A recovery of more than 90 % during the first extraction step is considered adequate.

Prior to any concentration steps, a keeper (high-boiling solvent, e.g. a high-boiling alkane or toluene) should be added. Make sure that the keeper does not interfere with the analytes of interest in the instrumental analysis.

5.3. Removal of sulphur and sulphur-containing compounds

The crude extracts usually require clean-up to remove co-extracted compounds (Wise *et al.,* 1995). Due to chlorophyll-like compounds extracted from the sediment, the raw extract is usually colored and also contains sulphur and sulphur-containing compounds, oil, PAH compounds and other natural and anthropogenic compounds. Selection of the appropriate clean-up method depends on the subsequent instrumental method to be used for analysis. Copper powder, wires, or gauze are the most common ways to remove the sulphur directly from an organic solvent. Copper can be applied during or after sediment extraction. Ultrasonic treatment might improve the removal of sulphur. If sulphur appears to be present in the final extract, the amount of copper used was insufficient and the clean-up procedure must be repeated.

Be aware that a prolonged contact between the sample and the copper may degrade some chlorinated pesticides.

Another possibility to remove sulphur is to add an aqueous saturated Na_2SO_3 solution to a hexane extract. In order to allow transfer of the HSO_3-ions to the organic phase, tetrabutylammonium (TBA) salts and isopropanol are added to the mixture. Subsequently, water is added to remove the isopropanol. The aqueous phase is then quantitatively extracted with hexane (Jensen *et al.,* 1977). If the extraction is performed with a polar solvent which is miscible with water, the Na_2SO_3 solution can be added directly after the extraction. If the extraction mixture also contains a non-polar solvent, then, depending on the ratio of the solvents, the addition of TBA and isopropanol may not be necessary. Any excess $Na_2SO_3$and reaction products can be removed by the addition of water and partitioning between the non-polar solvent and water.

Japenga *et al.* (1987) developed a column method for the removal of sulphur and sulphur-containing compounds. The column material is made by mixing an aqueous solution of Na_2SO_3 with Al_2O_3. Some NaOH is also added to improve the reaction with sulphur. Subsequently, the material is dried under nitrogen until a level of deactivation equivalent to 10 % water is reached. Storage must be under nitrogen because sulphite in this form may easily be oxidized to sulphate. Eluting the extract (hexane) through a column filled with this material results in removal of the sulphur in combination with further clean-up of the sediment extract.

Silver ions strongly bind sulphur and sulphur compounds. Loaded on silica, $AgNO_3$ is a very efficient sulphur-removing agent. It can be prepared by mixing dissolved $AgNO_3$ with silica and subsequently drying under nitrogen. Compounds containing aromatic rings are strongly retained, but for chlorinated hydrocarbons retention is reduced, probably due to shielding of the rings by the chlorine atoms. Retained compounds can easily be eluted by using cyclohexene, or another solvent with double bonds, as a modifier.

Elemental sulphur is strongly retained on a polystyrene divinylbenzene copolymer column as generally applied for gel permeation chromatography (GPC). In addition, this method combines the removal of sulphur with a clean-up.

Sometimes the use of multiple methods may be necessary for different samples. Several methods leave aromatic sulphur compounds in the extract which will elute from the GC column at the same retention time as the lower chlorinated biphenyls. The major part of these compounds can be removed by eluting a non-polar extract over a column containing silica loaded with concentrated sulphuric acid.

The recovery during clean-up should be analyzed carefully. In particular, treatment with H_2SO_4 results in loss of, e.g., dieldrin and endosulfanes. Also, the clean-up procedure with silver ions or copper can result in low recoveries for certain pesticides.

5.4. Further clean-up

Clean-up using normal phase chromatography is the most appropriate technique for the separation of the chlorinated hydrocarbons from other compounds. Using non-polar solvent, e.g., hexane or *iso*-octane, chlorinated hydrocarbons usually elute very rapidly.

All polar solvents used during extraction or sulphur-removal should be removed before further clean-up. The last concentration step is usually performed by evaporation with a gentle stream of nitrogen. Evaporation to dryness should always be avoided.

Deactivated Al_2O_3 (5–10 % water) is often used as the primary clean-up step through which usually a sufficiently clean extract for a gas chromatography- electron capture detector (GC-ECD) analysis of the sample is achieved, given that sulphur has been removed.

Deactivated SiO_2 (1–5 % water) does not retain chlorinated hydrocarbons (including planar CB) and only slightly retains polycyclic hydrocarbons when eluted with hexane or *iso*-octane.

For high activity silica (overnight at 180 °C), the retention of chlorinated hydrocarbons is negligible while PAH compounds are more strongly retained. The chlorinated hydrocarbons are eluted with non-polar solvents. Upon using more polar solvents (e.g., hexane/acetone) some interfering organochlorine pesticides might become eluted**.**

When GPC is used for removing sulphur (see 5.3 REMOVAL OF SULPHUR AND SULPHUR-CONTAINING COMPOUNDS) the removal of high molecular weight material can also be incorporated into the procedure. GPC does not separate chlorinated hydrocarbons from other compounds in the same molecular range (such as organochlorine pesticides), so additional clean-up is usually required.

For the separation of chlorinated hydrocarbons from lipids or oil components reverse-phase high-performance liquid chromatography (RP-HPLC) can be used. Due to the use of aqueous solvents in RP- HPLC solvents need to be changed from polar to non-polar and *vice versa*. Another option is the use of strong acid (e.g. H_2SO_4) to degrade the lipids; however, it may also degrade some pesticides.

6. Gas chromatography

In particular, for the large number of CB congeners (a total of 209) high-resolution capillary gas chromatography (GC) is the method of choices. However, the analysis of CBs in sediments should focus on the determination of selected individual congeners as it is currently impossible to separate all CBs in technical mixtures and from other ECD-detectable compounds. For example, the seven common indicator-PCBs should be analysed. If there is a desire to separate and analyse all congeners, it is recommended to use multidimensional gas chromatography (MGC) that makes use of two successive columns of different selectivity or polarity. However, the optimization is difficult (co-elution of some PCBs) and it is not routinely applied at commercial laboratories. Alternatively two ECD detectors and two parallel columns with different selectivity or polarity can be used, reducing the detection limit by a factor of 2 but improving the selectivity of co-elution PCBs by choosing the column with least overlap for suspected co-elutions.

Another option is to use GC-MS instrumentation for more selective determination.

For all GC methods, parameters have to be optimized.

6.1 Column dimensions

Column dimensions for the determination of chlorinated hydrocarbons are:

- length: minimum 50 m, and
- inner diameter (i. d.): maximum 0.25 mm.
- film thickness: 0.2 µm to 0.4 µm

Greater resolution can be obtained by reducing the inner diameter to 0.20 mm or less. Below a diameter of 0.15 mm the carrier gas pressure rises to values above 500 kPa, which are often not compatible with regular GC instruments. Also, the risk of leakage increases.

6.2 Stationary phases

A wide range of stationary phases can be used for the separation of chlorinated hydrocarbons (e.g., 94 % dimethyl-, 5 % phenyl-, 1 % vinyl polysiloxane, or 7 % phenyl-, 7 % cyanopropyl-, 86 % methyl-siloxane).

The use of more polar phases is sometimes limited as their maximum temperatures are not as high as for non-polar, chemically bonded phases. Stationary phases that separate chlorinated hydrocarbons on the

basis of molecular size, such as the liquid crystal phase, should not be used for monitoring purposes since they do not provide sufficient reproducibility.

6.3 Carrier gas

Preferentially, hydrogen should be used as the GC carrier gas. When using columns with very small inner diameters, the use of hydrogen is essential. The linear gas velocity should be optimized.

Appropriate settings for 0.25 mm i.d. columns range from 20–40 cm s^{-1} and for 0.15 mm i.d. columns from 30–50 cm s^{-1}.

6.4 Injection techniques

The two systems commonly used are splitless and on-column injection. Split injection should not be used due to strong discrimination effects. Other techniques such as temperature-programmed or pressure-programmed injection may have additional advantages, but should be thoroughly optimized before use.

The volume of the liner should be large enough to contain the gas volume of the evaporated injected solvent. When the liner is too small, memory effects may occur due to contamination of the gas tubing attached to the injector. Very large liner volumes can cause a poor transfer of early eluting components, so that peaks due to those analytes will be reduced or even disappear. In addition, the use of a light packing of (silylated) glass wool in the liner improves the response and reproducibility of the injection, but some organochlorine pesticides such as DDT may be degraded when this technique is applied.

An auto-sampler should be used.

6.5 Temperature programming

The temperature programme must be optimized for sufficient separation of the chlorinated hydrocarbons. A separation time of 60 to 120 minutes can be neccessary. In addition to a reproducible temperature programme, a fixed equilibration time is important for a correct analysis and constant retention times.

For further details and recommendations see Smedes and de Boer (1998).

6.6 Detection

The use of a mass spectrometer (MS) or tandem mass spectrometer (MS/MS) is highly recommended. MS gives the possibility to use ^{13}C labelled internal standards. Different ionization methods have been reported: Electron impact ionization (EI), Negative chemical ionization (NCI) or electron capture negative ionization (ECNI). Another used detector for the analysis of chlorinated hydrocarbons is the electron capture detector (ECD), but injection of chlorinated or oxygen-containing solvents should be avoided. NCI and ECNI is extremely sensitive for penta- to decachlorinated CBs (approximately ten-fold better than ECD), but can be less sensitive for less chlorinated PCBs (Law et al, 2011).

6.7 Identification

Usually, the compounds in the sample are identified based on their retention times as compared to those of the standard compounds analyzed under the same conditions. Moreover, upon using GC-MS compound characteristic mass fragments serve as additional identifiers.

7. Quantification

Automatically processed chromatograms should be reviewed if, e.g., the baseline is set correctly.

For calibration purposes a multilevel calibration with at least five concentration levels is recommended. The calibration curve should be linear and cover the working range. Obtained calibrations should be regularly validated in terms of precision and accuracy.

Prior to running a series of samples and standards, the GC or HPLC systems should be equilibrated by injecting at least one sample extract. In addition, standards used for multilevel calibrations should be

regularly distributed over the sample series so that matrix-and non-matrix-containing injections alternate. A sample series should include:

- a procedural blank;
- a laboratory reference material;
- at least five standards;
- one standard sample treated similarly to the samples for determination of the recovery.

The limit of quantification usually depends on the purpose of the investigation. The limit of quantification that can be achieved depends on the blank sample, the sample matrix, concentrations of interfering compounds, and the amount of sample. However, a limit of quantification of 0.1 ng g^{-1} (dry weight, fraction < 2 mm) or better should be attained for single compound analysis. The method for calculating the limit of determination should follow the advice in Part B-4.2.3 (COMBINE manual).

8. Quality Assurance

A number of measures should be taken to ensure sufficient quality of the analysis. Six main areas can be identified:

1. extraction efficiency and clean-up;
2. calibrant and calibration;
3. system performance;
4. long-term stability;
5. internal standards; and
6. frequent participation in interlaboratory proficiency testing schemes (e.g. QUASIMEME two times a year, www.quasimeme.org)

8.1. Extraction efficiency and clean-up

Extraction efficiency and clean-up can be controlled by analysing reference materials (Annex B-7). To determine the recovery rates of the clean-up and concentration steps, it is recommended to pass a standard solution (see 8.5. INTERNAL STANDARDS) through the entire procedure. The addition of corresponding internal standards to the samples is preferred.

If major losses have occurred, the results should not be reported.

8.2 Calibrant and calibration

Basically, calibration solutions should be stored in ampoules at a cool, dark place. Weight loss during storage should be recorded for all standards.

Calibration solutions from certified crystalline compounds should be used. However, the laboratory should have the appropriate equipment and expertise to handle these hazardous crystalline substances. Alternatively, certified compound solutions can be used. Preparation of two independent stock solutions allows cross-checks of the standard solutions if necessary.

8.3 System performance

The performance of the GC system can be monitored through regularly analyzing the resolution of two closely eluting compounds. A decrease in resolution indicates deteriorating GC conditions.

The signal-to-noise ratio of a low concentrated standard can give information on the condition of the detector. For example, a dirty MS-source can be recognized by the presence of a higher background signal, together with a reduced signal-to-noise ratio if not used in the SIM mode.

8.4 Long-term stability

One laboratory reference sample should be included in each series of samples. A quality control chart should be recorded for selected chlorinated hydrocarbons. If the warning limits are exceeded, the method should be checked for possible errors. When alarm limits are exceeded, the results obtained should not be reported.

A certified reference material should be analysed at least twice a year, and each time the procedure is changed.

8.5 Internal standards

Internal standards should be added to all standards and samples either in a fixed volume or by weight and should not interfere with the target analytes.

If possible, it is preferable to have internal standards corresponding as much as possible to each analyte, e.g. using isotopically labeled compounds combined with mass spectrometry as detection technique (e.g. pp-DDT-D8, isotopically labelled CBd).

After clean-up and before GC analysis, an additional internal standard can be added to evaluate the recovery of the internal standards added before clean-up.

8.6 Interlaboratory proficiency testing schemes

Each laboratory analysing sediments should participate in interlaboratory studies on the determination of chlorinated hydrocarbons in sediments on a regular basis (e.g. QUASIMEME offers the possibility to take part twice a year, www.quasimeme.org).

OSPAR COMMISSION

CEMP Guidelines for Monitoring Contaminants in Sediments

(OSPAR Agreement 2002-16)

Technical Annex 3: Determination of parent and alkylated PAHs in sediments

CEMP Guidelines for Monitoring Contaminants in Sediments

(OSPAR Agreement 2002-16)

Technical Annex 3: Determination of parent and alkylated PAHs in sediments

1. Introduction

Polycyclic aromatic hydrocarbons (PAHs) consist of a variable number of fused aromatic rings. By definition, PAHs contain at least two fused rings. PAHs arise from incomplete combustion processes and from both natural and anthropogenic sources, although the latter generally predominate. PAHs are also found in oil and oil products, and these include a wide range of alkylated PAHs formed as a result of diagenetic processes, whereas PAHs from combustion sources comprise mainly parent (non-alkylated) PAHs. Metabolites of some of the high MW PAHs are potent animal and human carcinogens – benzo[*a*]pyrene is the prime example. Carcinogenic activity is closely related to structure. Benzo[*e*]pyrene and the four benzofluoranthene isomers all have a molecular weight of 252 Da, however they are much less potent than benzo[*a*]pyrene. Less is known about toxicity of alkylated PAHs. However, one study has demonstrated that alkylated PAHs may have increased toxicity compared to the parent compound (Marvanova *et al.,* 2008).

This Technical Annex provides advice on the analysis of parent and alkylated polycyclic aromatic hydrocarbons (PAH) in total sediment, sieved fractions, and suspended particulate matter. The analysis of in sediments generally includes extraction with organic solvents, clean-up, high performance liquid chromatography (HPLC) with ultraviolet or fluorescence detection or gas chromatographic (GC) separation with flame ionisation (FID) or mass spectrometric (MS) detection (e.g., Fetzer and Vo-Dinh, 1989; Wise *et al*., 1995). All steps in the procedure are susceptible to insufficient recovery and/or contamination. Quality control procedures are recommended in order to check the performance of the method. These guidelines are intended to encourage and assist analytical chemists to critically reconsider their methods and to improve their procedures and/or the associated quality control measures, where necessary.

These guidelines are not intended as a complete laboratory manual. If necessary, guidance should be sought from highly specialised research laboratories. Whichever procedure is adopted, each laboratory must demonstrate the validity of each step of its procedure. In addition, the use of a second (and different method), carried out concurrently to the routine procedure, is recommended for validation. The analyses must be carried out by experienced staff.

2. Pre-treatment and Storage

2.1 Contamination

Sample contamination may occur during sampling, sample handling, pre-treatment and analysis, due to the environment, the containers or packing materials used, the instruments used during sample preparation, and from the solvents and reagents used during the analytical procedures. Controlled conditions are therefore required for all procedures. In the case of PAHs, particular care must be taken

to avoid contamination at sea. On ships there are multiple sources of PAHs, such as the oils used for fuel and lubrication, and the exhaust from the ship's engines. It is important that the likely sources of contamination are identified and steps taken to preclude sample handling in areas where contamination can occur. A ship is a working vessel and there can always be procedures occurring as a result of the day-to-day operations (deck cleaning, automatic overboard bilge discharges, etc.) that could affect the sampling process. It is advisable to collect samples of the ship's fuel, bilge water, and oils and greases used on winches, etc., which can be used as fingerprinting samples at a later date, if there are suspicions of contamination in particular instances.

Freeze-drying of sediment samples may be a source of contamination due to the back-streaming of oil vapours from the rotary vacuum pumps. Furthermore drying the samples may result in losses of the lower molecular weight, more volatile PAHs through evaporation (Law *et al.*, 1994).

Plastic materials must not be used for sampling and storage owing to possible adsorption of the PAHs onto the container material. Samples should be transported in closed containers; a temperature of 25°C should not be exceeded. If the samples are not analysed within 48 hours after sampling, they must be stored at 4°C (short-term storage). Storage over several months is only possible for frozen, (i.e., below −20°C) and/or dried samples (Law and de Boer, 1995).

As PAHs are sensitive to photo-degradation, exposure to direct sunlight or other strong light must be avoided during storage of the samples as well as during all steps of sample preparation, including extraction and storage of the extracts (Law and Biscaya, 1994). The use of amber glassware is strongly recommended.

2.2 Blanks

The procedural detection limit is determined by the blank value. In order to keep the blank value as low as possible, PAHs or other interfering compounds should be removed from all glassware, solvents, chemicals, adsorption materials, etc., that are used in the analysis. The following procedures should be used:

- glassware should be thoroughly washed with detergents and rinsed with an organic solvent prior to use. Further cleaning of the glassware, other than calibrated instruments, can be carried out by heating at temperatures >250°C;
- all solvents should be checked for impurities by concentrating the amount normally used to 10% of the normal end volume. This concentrate can then be analysed by GC and should not contain significant amounts of PAHs or other interfering compounds;
- all chemicals and adsorption materials should be checked for impurities and purified (e.g., by heating or extraction), if necessary. Soxhlet thimbles should be pre-extracted. Glassfibre thimbles are preferred over paper thimbles. Alternatively, full glass Soxhlet thimbles, with a G1 glass filter at the bottom, can be used. The storage of these supercleaned materials for a long period is not recommended, as laboratory air can contain PAHs that will be absorbed by these materials. Blank values occurring despite all the above-mentioned precautions may be due to contamination from the air. The most volatile compounds will usually show the highest blanks (Gremm and Frimmel, 1990).
- Glassfibre filters used for the PLE (pressurised liquid extraction) method should be heated at 450°C overnight.

3. Pre-treatment

Before taking a subsample for analysis, the samples should be sufficiently homogenised. The intake mass is dependent on the expected concentrations. For the marine environment, as a rule of thumb, the mass of sample taken for analysis can be equal to an amount representing 50–100 mg organic carbon. PAHs can be extracted from wet or dried samples. However, storage, homogenisation and extraction are much easier when the samples are dry. Care must be taken if freeze-drying samples for the reasons described in 2.1. Possible losses and contamination have to be checked. Contamination can be checked by exposing 1–2 g C18-bonded silica to drying conditions and analysing it as a sample (clean-up can be omitted) (Smedes and de Boer, 1997). Contamination during freeze-drying can be reduced by placing a lid, with a hole about 3 mm in diameter, on the sample container, while evaporation of the water is not hindered.

4. Extraction and clean-up

Exposure to light must be kept to a minimum during extraction and further handling of the extracts (Law and Biscaya, 1994). Since photo-degradation occurs more rapidly in the absence of a sample matrix, first of all the standard solution used for checking the recovery of the procedure will be affected, allowing a proper detection of the influence of light. The most photo-sensitive PAH is benzo[*a*]pyrene, followed by anthracene.

4.1 Wet sediments

Wet sediments should be extracted using a stepwise procedure by mixing with organic solvents. Extraction is enhanced by shaking, Ultra Turrax mixing, ball mill tumbling or ultrasonic treatment. Water-miscible solvents, such as acetone, methanol, or acetonitrile, are used in the first step. The extraction efficiency of the first step will be low as there is a considerable amount of water in the liquid phase. For sufficient extraction, at least three subsequent extractions are needed. The contact time with the solvent should be sufficient to complete the desorption of the PAHs out of the sediment pores. Heating by microwave or refluxing will accelerate this process.

When utilising a Soxhlet, the extraction of wet sediments should be conducted in two steps. First, a polar solvent, such as acetone, is used to extract the water from the sediment, then the flask is replaced and the extraction continued with a less polar solvent or solvent mixture (e.g., acetone/hexane). Thereafter, the extracts must be combined. For both batch and Soxhlet extraction, water must be added to the combined extracts and the PAHs must be extracted to a non-polar solvent.

Extraction of wet sediments by pressurised liquid extraction (PLE) is a more recent method, requiring less solvent and time for the extraction process. Wet sediment is dried by mixing with sufficient anhydrous sodium sulphate to form a free flowing mixture and is packed into stainless steel tubes for extraction. Extractions are performed at elevated temperatures and pressures. Various extracting solvents (DCM, acetone, methanol, acetonitrile, hexane, DCM: acetone [1:1], hexane:acetone [1:1] were investigated by Saim *et al.* (1998) and as long as the solvent polarity was >1.89 (*i.e*. all except hexane) no significant differences were noted. Extraction temperatures can be manipulated to suit the analytical requirements.

4.2 Dry sediments

Although all the methods mentioned above can also be used for dried sediments, Soxhlet extraction is the most frequently applied technique to extract PAHs from dried sediments. Medium-polar

solvents such as dichloromethane or toluene, or mixtures of polar and non-polar solvents can be used. When using dichloromethane, losses of PAHs have occasionally been observed (Baker, 1993). Although toluene is not favoured because of its high boiling point, it should be chosen as solvent when it is expected that sediment samples contain soot particles. For routine marine samples, the use of a mixture of a polar and a non-polar solvent (e.g., acetone/hexane (1/3, v/v)) is recommended.

The extraction can be carried out with a regular or a hot Soxhlet (Smedes and de Boer, 1997). A sufficient number of extraction cycles must be performed (approximately 8 hours for the hot Soxhlet and 12 to 24 hours for normal Soxhlet). The extraction efficiency has to be checked for different types of sediments by a second extraction step. These extracts should be analysed separately.

PLE can also be used for the extraction of freeze-dried sediments. Instead of anhydrous sodium sulphate to dry the sediment the sample is mixed with a clean sand or diatomaceous earth to increase the surface area of the sediment. The same solvent mixtures detailed above for wet sediment extraction can be used for the dry sediments. Supercritical fluid extraction (SFE) has also been used for the extraction of organic compounds. The optimum conditions may vary for specific sediments (e.g., Dean *et al*., 1995; Reimer and Suarez, 1995).

4.3 Clean-up

The crude extract requires a clean-up to remove the many other compounds which are co-extracted (e.g., Wise *et al*., 1995). Due to chlorophyll-like compounds extracted from the sediment, the raw extract will be coloured and also contain sulphur and sulphur-containing compounds, oil, and many other natural and anthropogenic compounds. Selection of the appropriate clean-up method depends on the subsequent instrumental method to be used for analysis. Prior to the clean-up, the sample must be concentrated and any polar solvents used in the extraction step should be removed. The recommended acetone/hexane mixture will end in hexane when evaporated because of the formation of an azeotrope. Evaporation can be done either using a rotary evaporator or parallel evaporating systems such as Syncore. Especially for the rotary evaporator, care should be taken to stop the evaporation in time at about 5 ml. For further reducing the volume, a gentle stream of nitrogen should be applied. The extract should never be evaporated to dryness. The drawback of the rotary evaporator is that more volatile components may be lost during the nitrogen drying stage whilst the heavier components stick to the glassware. The Buchi Syncore Analyst also uses glass tubes but the system is sealed, avoiding contamination from the lab air during evaporation. It does not use a nitrogen stream, thus reducing the loss of volatiles and if the flushback module is fitted the sides of the tubes are rinsed automatically thus reducing the loss of the heavier components.

For removing more polar interferences from the extract, deactivated aluminium oxide (10 % water), eluted with hexane, as well as silica or modified silica columns, e.g., aminopropylsilane, eluted with toluene or a semipolar solvent mixture such as hexane/acetone (95/5, v/v) or hexane/dichloromethane (98/2, v/v), can be used. Gel permeation chromatography (GPC) can be used to remove high molecular weight material and sulphur from the extracts.

For GC-MS analysis, sulphur should be removed from the extracts, in order to protect the detector. This can be achieved by the addition of copper powder, wire or gauze during or after Soxhlet extraction. Copper can also be added to the PLE cell, however, this is not always sufficient and further treatment with copper may be required following extraction. Ultrasonic treatment might improve the removal of sulphur. As an alternative to copper, other methods can be used (Smedes and de Boer, 1997).

Aliphatic hydrocarbons originating from mineral oil interfere with the flame ionisation detection. They can be removed from the extract by fractionation over columns filled with activated aluminium oxide or silica. The first fraction eluting with hexane is rejected. The PAHs elute in a second fraction with a more polar solvent, e.g., diethylether or acetone/hexane. When applying fractionation, the elution pattern has to be checked frequently. This should be carried out in the presence of sample matrix, as that can partially deactivate the clean-up column, resulting in earlier elution of the PAHs than in a standard solution.

Gel permeation chromatography (GPC) and high performance liquid chromatography (HPLC) based methods are also employed (Nondek *et al.,* 1993; Nyman *et al.,* 1993; Perfetti *et al.*, 1992). The major advantages of using HPLC-based clean-up methods are their ease of automation and reproducibility.

Isocratic HPLC fractionation of the extract can be used to give separate aliphatic and aromatic fractions (Webster *et al*., 2002). A metal free silica column is used for the clean up/fractionation as dibenzothiophene (DBT) can be retained on ordinary silica columns. The split time is determined by injection of a solution containing representative aliphatic and PAH standards. The silica column is regenerated by a cleaning cycle after a set number of samples. If PAHs are to be analysed by HPLC and there are significant amounts of alkylated PAHs present then the removal of the alkylated PAHs may be difficult.

4.4 Pre-concentration

In the methods suggested above, all result in an extract in which non-polar solvents are dominant. The sample volume should be 2 ml or greater to avoid errors when transferring solvents during the clean-up stages. Syncore parallel evaporators can be used with careful optimisation of the evaporation parameters. Evaporation of solvents using a rotary-film evaporator should be performed at low temperature (water bath temperature of 30°C or lower) and under controlled pressure conditions, in order to prevent losses of the more volatile PAHs such as naphthalenes. For the same reasons, evaporation to dryness must be avoided. When reducing the sample to final volume, solvents can be removed by a stream of clean nitrogen gas. Suitable solvents for injection into the GC-MS include pentane, hexane, heptane, *iso*-hexane, and *iso*-octane.

5. Selection of PAHs to be determined

The choice of PAHs to be analysed is not straightforward, both because of differences in the range of PAH compounds resulting from combustion processes and from oil and oil products, and also because the aims of specific monitoring programmes can require the analysis of different representative groups of compounds. PAHs arising from combustion processes are predominantly parent (unsubstituted) compounds, whereas oil and its products contain a much wider range of alkylated compounds in addition to the parent PAHs. This has implications for the analytical determination, as both HPLC-based and GC-based techniques are adequate for the determination of a limited range of parent PAHs in samples influenced by combustion processes, whereas in areas of significant oil contamination and following oil spills only GC-MS has sufficient selectivity to determine the full range of PAHs present. The availability of pure individual PAHs for the preparation of standards is problematic and limits both the choice of determinands and, to some degree, the quantification procedures that can be used. The availability of reference materials certified for PAHs is also rather limited. A list of target parent and alkylated PAHs suitable for environmental monitoring is given in Table A2.1, and this differs both from the list previously developed within ICES specifically for

intercomparison purposes, and the historic list of Borneff. In both cases, the lists were concentrated on a subset of parent (predominantly combustion-derived) PAHs due to analytical limitations. This approach completely neglects the determination of alkylated PAHs, which allows the interpretation of PAH accumulation from multiple sources including those due to oil inputs. It will not be necessary for all of these PAH compounds and groups to be analysed in all cases, but an appropriate selection can be made from this list depending on the specific aims of the monitoring programme to be undertaken.

Table A2.1 Compounds of interest for environmental monitoring for which the guidelines apply. For compounds in italics standards are not available for any isomers in this group.

Compound	MW	Compound	MW
Naphthalene	128	Benzo[b]naphtho[2,3-*d*]thiophene	234
C_1-Naphthalenes	142	C_1-benzonaphthothiophenes	248
C_2-Naphthalenes	156	C_2-Fluoranthenes/Pyrenes	230
C_3-Naphthalenes	170	Benz[*a*]anthracene	228
C_4-Naphthalenes	184	Chrysene	228
Acenaphthylene	152	2,3-Benzanthracene	228
Acenaphthene	154	C_1- Benz[*a*]anthracene/ Chrysene	242
Biphenyl	154	C_2- Benz[*a*]anthracene/ Chrysene	256
Fluorene	166	C_3- Benz[*a*]anthracene/ Chrysene	270
C_1-Fluorenes	180	Benzo[*a*]fluoranthene	252
C_2-Fluorenes	*194*	Benzo[*b*]fluoranthene	252
C_3-Fluorenes	*208*	Benzo[*j*]fluoranthene	252
Dibenzothiophene	184	Benzo[*k*]fluoranthene	252
C_1-Dibenzothiophenes	198	Benzo[*e*]pyrene	252
C_2-Dibenzothiophenes	212	Benzo[*a*]pyrene	252
C_3-Dibenzothiophenes	226	Perylene	252
Phenanthrene	178	Indeno[1,2,3-*cd*]pyrene	276
Anthracene	178	Benzo[*ghi*]perylene	276
C_1-Phenanthrenes/Anthracenes	192	Dibenz[*a,h*]anthracene	278
C_2-Phenanthrenes/Anthracenes	206	Benzo[*k*]fluoranthene	252
C_3-Phenanthrenes/Anthracenes	220	Cyclopenta[*cd*]pyrene	226
Fluoranthene	202	Naphtho[2,1-*a*]pyrene	302
Pyrene	202	Dibenz[*a,e*]pyrene	302
C_1-Fluoranthenes/Pyrenes	216	Dibenz[*a,i*]pyrene	302
Benzo[*b*]naphtho[2,1-*d*]thiophene	234	Dibenz[*a,l*]pyrene	302
Benzo[*b*]naphtho[1,2-*d*]thiophene	234	Dibenz[*a,h*]pyrene	302

6. Instrumental determination of PAHs

The greatest sensitivity and selectivity in routine analysis for parent PAH is achieved by combining HPLC with fluorescence detection (HPLC-UVF) or capillary gas chromatography with mass spectrometry (GC-MS). However, for the analysis of parent and alkylated PAHs GC-MS is the method of choice. In terms of flexibility, GC-MS is the most capable technique, as in principle it does not limit the selection of determinands in any way, while HPLC is suited only to the analysis of parent PAHs. In the past, analyses have also been conducted using HPLC with UV-absorption detection and GC with flame-ionisation detection, but neither can be recommended for alkylated PAHs because of their relatively poor selectivity. Both in terms of the initial capital cost of the instrumentation, and the cost per sample analysed, HPLC-UVF is cheaper than GC-MS. With the advent of high-sensitivity benchtop

GC-MS systems, however, this cost advantage is now not as marked as in the past, and the additional information regarding sources available makes GC-MS the method of choice.

Limits of determination within the range of 0.05 µg kg^{-1} dry weight for individual PAH compounds should be achievable by GC-MS.

6.1 GC-MS

The three injection modes commonly used are splitless, on-column and PTV (programmed temperature vaporiser). Automatic sample injection should be used wherever possible to improve the reproducibility of injection and the precision of the overall method. If splitless injection is used, the liner should be of sufficient capacity to contain the injected solvent volume after evaporation. For PAH analysis, the cleanliness of the liner is also very important if adsorption effects and discrimination are to be avoided, and the analytical column should not contain active sites to which PAHs can be adsorbed. Helium is the preferred carrier gas, and only capillary columns should be used. Because of the wide boiling range of the PAHs to be determined and the surface-active properties of the higher PAHs, the preferred column length is 25–50 m, with an internal diameter of 0.15 mm to 0.3 mm. Film thicknesses of 0.2 µm to 1 µm are generally used; this choice has little impact on critical resolution, but thicker films are often used when one-ring aromatic compounds are to be determined alongside PAHs, or where a high sample loading is needed. No stationary phase has been found on which all PAH isomers can be resolved; the most commonly used stationary phase for PAH analysis is 5% phenyl methylsilicone (DB-5 or equivalent). This will not, however, resolve critical isomers such as benzo[*b*], [*j*] and [*k*]fluoranthenes, or chrysene from triphenylene. Chrysene and triphenylene can be separated on other columns, if necessary such as a 60 m non-polar column such a DB5MS. For PAHs there is no sensitivity gain from the use of chemical ionisation (either positive or negative ion), so analyses are usually conducted in electron-impact mode at 70eV. Quadrupole instruments are used in single ion monitoring to achieve greater sensitivity. The masses to be detected are programmed to change during the analysis as different PAHs elute from the capillary column. In SIM the molecular ion is used for quantification. Qualifier ions can be used to confirm identification but they are limited for PAHs. Triple quadropole mass spectrometry can also be used and will give greater sensitivity. Some instruments such as ion-trap and time of flight mass spectrometers exhibit the same sensitivity in both modes, so full scan spectra can be used for quantification.

An example of mass spectrometer operating conditions in SIM mode is given in Table A2.2. The ions are grouped and screened within GC time windows of the compounds. In general the number of ions should not be greater than 20. The dwell time is an important parameter and should be close for each ion. For GC capillary column analysis a dwell time should not be shorter than 20 ms, while a sum of a dwell in each retention time windows should not be greater than 500 ms. An example of conditions that can be used along with dwell times are shown in Table A2.2.

Table A.2.2 Example of operational conditions for the GC-MS analysis of parent and alkylated PAHs.

Group N°	Retention time (min)	Dwell time (ms)	Ions in group (AMU)					
1	8.00	100	128	136	142			
2	21.00	100	152	156	160			
3	23.70	100	154	164	168	170		
4	26.80	80	166	176	180	182	184	
5	31.60	80	178	184	188	194	196	198
6	35.30	100	192	198				
7	36.60	100	206	212				
8	39.40	80	202	206	212	216	220	226
9	44.65	100	216	220				
10	45.30	100	226	228	230	234	240	
11	48.58	90	242	248				
12	52.00	100	252	256	264	266		
13	59.00	100	266	276	278	288		

Alkylated homologues of PAHs (C1–C4), mainly associated with petrogenic sources, contain a number of different isomers that can give very complex but distinct distribution profiles when analysed by GC-MS. Integration of each isomer separately is difficult for most alkylated PAHs. 1- and 2-Methyl naphthalene give well resolved peaks that can be quantified separately. C1-Phenanthrene/anthracene gives five distinct peaks corresponding to 3-methyl phenanthrene, 2-methyl phenanthrene, 2-methyl anthracene, 4- and 9-methyl phenanthrene and 1-methyl phenanthrene. These may be integrated as a group or as separate isomers. For all other alkylated PAHs the area for all isomers may be summed and quantified against a single representative isomer. This method will, however, lead to an overestimation of the concentration as may include non alkylated PAHs. Examples of integrations of both parent and alkylated PAHs are shown in Appendix 1.

7. Calibration and quantification

7.1 Standards

The availability of pure PAH compounds are limited. Although most of the parent compounds can be purchased as pure compounds, the range of possible alkyl-substituted PAHs is vast and only a limited selection of them can be obtained. PAH standards are available for at least one isomer of most alkyl group listed in Table A2.1. A range of deuterated PAHs (normally 5 to 7) should be used as internal standards to cover the range of PAHs being analysed in samples. A range of fully-deuterated parent PAHs is available for use as standards in PAH analysis. Suitable standards could range from d_8-naphthalene to d_{14}-dibenz[*a,h*]anthracene. Crystalline PAHs of known purity should be used for the

preparation of calibration standards. If the quality of the standard materials is not guaranteed by the producer or supplier (as for certified reference materials), then it should be checked by GC-MS analysis. Solid standards should be weighed to a precision of 10^{-5} grams. Calibration standards should be stored in the dark because some PAHs are photosensitive, and ideally solutions to be stored should be sealed in amber glass ampoules or sealed GC vials. Otherwise, they can be stored in a refrigerator in stoppered measuring cylinders or flasks that are gas tight to avoid evaporation of the solvent during storage.

7.2 Calibration

Multilevel calibration with at least five calibration levels is preferred to adequately define the calibration curve. In general, GC-MS calibration is linear over a considerable concentration range but may exhibit a change of slope at very low concentrations. Quantification should be conducted in the linear region of the calibration curve. A separate calibration curve may be used where sample concentrations are very low. An internal standard method should be employed, using a range of deuterated PAHs as internal standards.

7.3 Recovery

The recovery of analytes should be checked and reported. Given the wide boiling range of the PAHs to be determined, the recovery may vary with compound group, from the volatile PAHs of low molecular weight to the larger compounds. Deuterated standards can be added in two groups: those to be used for quantification are added at the start of the analytical procedure, whilst those from which the absolute recovery will be assessed are added prior to GC-MS injection. This allows the recovery to be calculated.

8. Analytical quality control

Planners of monitoring programmes must decide on the accuracy, precision, repeatability, and limits of detection and determination, which they consider acceptable. Achievable limits of determination for each individual component using GC-MS are 0.05 µg kg^{-1} dry weight.

Further information on analytical quality control procedures for PAHs can be found elsewhere (Law and de Boer, 1995). A procedural blank should be measured with each sample batch, and should be prepared simultaneously using the same chemical reagents and solvents as for the samples. Its purpose is to indicate sample contamination by interfering compounds, which will result in errors in quantification. The procedural blank is also very important in the calculation of limits of detection and limits of quantification for the analytical method. In addition, a laboratory reference material (LRM) should be analysed within each sample batch. The LRM must be homogeneous and well characterised for the determinands of interest within the analytical laboratory. Ideally, stability tests should have been undertaken to show that the LRM yields consistent results over time. The LRM should be of the same matrix type (e.g., liver, muscle, mussel tissue) as the samples, and the determinand concentrations should be in the same range as those in the samples. Realistically, and given the wide range of PAH concentrations encountered, particularly in oil spill investigations, this is bound to involve some compromise. The data produced for the LRM in successive sample batches should be used to prepare control charts. It is also useful to analyse the LRM in duplicate from time to time to check within-batch analytical variability. The analysis of an LRM is primarily intended as a check that the analytical method is under control and yields acceptable precision, but a certified reference material (CRM) of a similar matrix should be analysed periodically in order to check the method bias.

A marine sediment (NIST SRM 1941b)[1] is available, with certified values for 24 PAHs and a further 44 as reference (non-certified) values. At regular intervals, the laboratory should participate in an intercomparison or proficiency exercise in which samples are circulated without knowledge of the determinand concentrations, in order to provide an independent check on performance.

9. Data reporting

The calculation of results and the reporting of data can represent major sources of error, as has been shown in intercomparison studies for PAHs. Control procedures should be established in order to ensure that data are correct and to obviate transcription errors. Data stored on databases should be checked and validated, and checks are also necessary when data are transferred between databases. Data should be reported in accordance with the latest ICES reporting formats.

HELCOM

Guidelines for the determination of polycyclic aromatic hydrocarbons (PAH) in sediment

Guidelines for the determination of polycyclic aromatic hydrocarbons (PAH) in sediment

1. Introduction

This Technical note provides advice on the analysis of polycyclic aromatic hydrocarbons (PAH) in total marine sediments, sieved fractions, and suspended particulate matter. The analysis of PAH compounds in sediments basically includes extraction with organic solvents, clean-up, and separation through high performance liquid chromatography (HPLC) with ultraviolet (UV) or fluorescence detection or gas chromatographic separation (GC) with flame ionization (FID) or mass spectrometric (MS) detection (Kassim & Barcelo, 2009, 1989; Wise *et al.,* 1995).

All steps of the procedure are susceptible to insufficient recovery and contamination. Quality control measures are recommended in order to regularly monitor the performance of the method. These guidelines are intended to encourage and assist analytical chemists to critically review their methods and to improve their procedures and quality assurance measures, if necessary.

These guidelines are not intended as complete laboratory manual. If necessary, guidance should be sought from specialized laboratories. Laboratories should demonstrate validity of each methodological step.

Moreover, use of an alternative method, carried out concurrently to the routine procedure, is recommended for validation.

Contracting parties should follow the HELCOM monitoring guideline but minor deviations from this are acceptable if the method achieves comparable results. Validation of the adopted method needs to be performed on the relevant matrix and concentration range e.g. by taking part in intercomparison studies or proficiency testing schemes.

2. Sampling and storage

The major criterion for successful sediment sampling is to ensure undisturbed sample stratification. (For further details about sampling, see Annex B-13, Appendix 3 "Technical note on the determination of heavy metals in marine sediments" of the HELCOM COMBINE manual.)

Plastic materials should not be used for sampling and storage due to the risk of adsorption of PAH compounds onto the container material. Samples should be transported in closed containers and preferentially at temperatures below 10 °C. The samples should be stored at 4 °C as soon as possible, but at least if they have not been analysed within 48 hours after collection (short-term storage). For long-term storage over several months the samples should be frozen below -20 °C or dried (Law and de Boer, 1995). When drying, avoid methods with substantial risk of losing volatile substances (see Chapter 4: Pretreatment).

PAH compounds are sensitive to photo-degradation and, thus, exposure to direct sunlight or other light sources should be avoided during storage as well as during all steps of sample preparation (Law and Biscaya, 1994). The use of amber glassware is strongly recommended.

3. Blanks and contamination

Basically, care should be taken to avoid contaminations during all steps of the analytical chain, including sampling, extraction and clean-up.

In order to reduce blank and sample contaminations to a minimum it is strongly recommended to pretreat all used glassware, solvents, chemicals, adsorption materials, etc., as follows:

- Glassware should be thoroughly washed with detergents and can be furthered cleaned, other than calibrated instruments, by heating at temperatures > 250 °C. The glassware should be rinsed with an organic solvent prior to use.
- All solvents should be analyzed for impurities by concentrating to 10 % of the regular final volume. This concentrate is then analysed similarly to a sample by HPLC or GC. The solvent blank should not contain target analytes or other interfering compounds in higher concentrations than specified by the laboratory.
- All chemicals and adsorption materials should be analyzed for impurities and purified (e.g., by heating or extraction), if necessary. Soxhlet thimbles should be pre-extracted. Glass fiber thimbles are preferred over paper thimbles. Alternatively, full glass Soxhlet thimbles, with a G1 glass filter at the bottom, can be used.

Storage of these supercleaned materials for a longer period is not recommended, as laboratory air might contain PAH compounds which can adsorb onto these materials. Therefore, contaminated blank samples might occur despite precautionary measures due to contamination from the air. Volatile compounds, in particular naphthalene and phenanthrene, are usually the most common contaminants in blank samples (Gremm and Frimmel, 1990). Therefore, if possible, critical steps should be done in a clean bench.

4. Pretreatment

The samples should be thoroughly homogenized before subsampling for analysis. The amount of samples usually depends on the expected concentrations. For the marine environment, the amount of sample should be equal to an amount representing 50–100 mg of organic carbon.

PAHs can be extracted from wet or dried samples. However, storage, homogenization and extraction are easier to handle with dried samples.

Drying the samples at ambient or elevated temperatures as well as freeze-drying may alter the concentrations, e.g., by contamination or loss of compounds through evaporation (Law *et al.,* 1994). Therefore, potential losses and contaminations should be analyzed in advance, e.g. by exposing 1–2 g CIS-bonded silica to the drying conditions and subsequent extraction and analysis (clean-up can be omitted) (Smedes and de Boer, 1998). For evaluation of potential losses, analytes identical or similar to PAHs need to be added to the material. However, bear in mind that added analytes can behave differently from analytes that have interacted longer with the matrix material and therefore may be sorbed more strongly. To avoid contamination during freeze-drying, placing a lid with a hole of about 3 mm in diameter on the sample container is suggested.

Chemical drying of samples can be performed by grinding with Na_2SO_4, or $MgSO_4$ until the sample reaches a sandy consistency. It is essential that several hours elapse between grinding and extraction to allow for complete dehydration of the sample. Residual water will decrease extraction efficiency.

5. Extraction and clean-up

Exposure to light must be kept to a minimum during extraction and further handling of the extracts (Law and Biscaya, 1994). The most photo-sensitive PAH is benzo[*a*]pyrene, followed by anthracene. Photo-degradation occurs more rapidly in the absence of a sample matrix. Therefore, the PAH standard solution should be regularly analyzed for their PAH content.

Other extraction and clean-up methods than those described below may be used, provided that the methods have been tested and found equivalent to established methods regarding e.g. recovery. For naphthalene, which can easily be lost in several steps during sample preparation, headspace or purge and trap analysis might provide a suitable alternative to extraction methods.

5.1 Extraction of wet sediments

A commonly used and very efficient method for PAH extraction from sediments is alkaline saponification. This method requires only a short extraction time (approximately 1.5 hrs under the reflux) and it also eliminates organic sulphur and other interfering compounds such as lipids. The resulting extract is easy to clean up.

Wet sediments could also be extracted using a stepwise procedure by mixing with organic solvents. Extraction is enhanced by shaking, Ultra Turrax mixing, ball mill tumbling or ultrasonic treatment. Water-miscible solvents, such as acetone, methanol, or acetonitrile, are used in the first step. The extraction efficiency of the first step will be low as there is a considerable amount of water in the liquid phase. In a second step a less polar solvent / solvent mixture such as acetone/hexane should be used. It has to be kept in mind that hexane is a lot more toxic than similar solvents such as pentane, heptane, cyclohexane, isohexane. For sufficient extraction at least three subsequent extractions are needed. The contact time with the solvent should be long enough to allow complete desorption of the PAH compounds from the sediment pores. The contact time might be up to 24 hours which basically depends on the type of sediment.

The required contact time of the sediment with the solvent can be reduced by using microwave extraction, supercritical fluid extraction, Soxhlet extraction or pressured liquid extraction (e.g. ASE). Soxhlet or ASE extraction of wet sediments should be conducted in two steps. First, a polar solvent, such as acetone, is

used to extract the water from the sediment. In a second step the collecting flask is replaced and the extraction will be continued using a less polar solvent or solvent mixture such as acetone/hexane or toluene. Thereafter, the extracts will be combined.

To separate the water and keep the PAHs in a solvent that is compatible with the continued analysis different methods can be used. For example, water will be added to the combined extracts and the PAH compounds will be extracted to a non-polar solvent. Another possibility is to add Na_2SO_4 to bind water.

Extraction should be conducted with a sufficient number of extraction cycles. Extraction efficiency should be analyzed for different types of sediments through a second extraction step. The extracts will be analysed separately and compared. A recovery of more than 90 % during the first extraction step is considered adequate.

5.2 Extraction of dry sediments

The methods described above can also be used for dried sediments. However, pressurized liquid extraction (PLE) is the most frequently applied technique to extract PAH compounds from dried sediments and it is recommended over mixing methods, in particular for dry samples.

Medium-polar solvents such as dichloromethane or toluene or mixtures of polar and non-polar solvents can be used. When using dichloromethane, losses of PAHs have occasionally been observed. Although toluene is not favored due to its high boiling point, it should be chosen when sediment samples could contain soot particles. For routine marine samples, the use of a mixture of a polar and a non-polar solvent such as acetone/hexane (1/3, v/v) is recommended.

Extraction should be conducted with a sufficient number of extraction cycles. Extraction efficiency should be analyzed for different types of sediments through a second extraction step. The extracts will be analysed separately and compared. A recovery of more than 90 % during the first extraction step is considered adequate.

5.3 Clean-up

The crude extracts usually require clean-up to remove co-extracted compounds (Wise *et al.,* 1995). Due to chlorophyll-like compounds extracted from the sediment, the raw extract is usually colored and also contains sulphur and sulphur-containing compounds, oil and other natural and anthropogenic compounds. Selection of the appropriate clean-up method depends on the subsequent instrumental method to be used for analysis.

Prior to the clean-up, the sample must be concentrated and polar solvents used during extraction should be removed. The recommended acetone/hexane mixture will result in hexane after evaporation due to the formation of an azeotrope if hexane is abundant. Evaporation can be done using either a Kuderna-Danish,a rotary evaporator or other evaporation system (e.g. parallel evaporation). In particular, upon using rotary or parallel evaporation, ambient or mild vacuum conditions and a water bath temperature of not more than 30 °C should be applied and care should be taken to stop evaporation at a sample volume of about 2 ml or by using automatic systems. For further volume reduction a gentle stream of nitrogen can be applied. The extract should never be evaporated to dryness.

To remove polar interferences from the extract the following chromatographic procedures can be used:

- desactivated aluminium oxide (10 % water), eluted with hexane – in particular upon using HPLC-Fluorescence for subsequent analysis
- silica or modified silica columns, e.g., aminopropylsilane or cyanopropyl phase eluted with toluene or a semipolar solvent mixture such as hexane/acetone (95/5, v/v) or hexane/dichloromethane (98/2, v/v)

- Gel permeation chromatography (LC-GPC) can be used to remove high molecular weight material and sulphur from the extracts

For GC-MS analysis sulphur should be removed from the extracts in order to protect the detector. This can be achieved by the addition of copper powder, wire or gauze during or after organic solvent extraction. Ultrasonic treatment might improve the removal of sulphur. Alternative methods to the use of copper were reported by (Smedes and de Boer, 1998).

Analysis by GC-FID or HPLC-UV requires a more elaborate clean-up. Aliphatic hydrocarbons originating from mineral oil interfere with the flame ionization detection. They can be removed from the extract by fractionation over columns filled with activated aluminium oxide or silica as described above. However, a first fraction is eluted with only hexane and then rejected. The PAHs elute in the second fraction with a more polar solvent, e.g., diethylether or acetone/hexane. When applying fractionation, the elution pattern has to be checked frequently and in the presence of sample matrix, as this can partially deactivate the clean-up column resulting in earlier elution of the PAH compounds than in the standard solution.

Alkylated PAHs are difficult to remove from extracts by column clean-up. When excessive amounts of these compounds are present, they may interfere with HPLC analysis and such samples should be better analysed by GC-MS. An alternative could be preparative HPLC fractionation using a normal phase silica, cyanopropyl or aminopropyl column.

After clean-up, the eluate or fractions must be concentrated, to e.g. 1 ml. Any concentration method should be conducted carefully as described above as high volatility of the PAH compounds may result in losses during evaporation. HPLC and GC require different solvents for injection of the extract. With the methods suggested, obtained extracts are usually in non-polar solvents. However, for HPLC analysis even small amounts of non-polar solvents may result in a shift of retention time and broadening of the peaks (Reupert and Brausen, 1994). Acetonitrile should be used preferentially as the PAH exhibit higher stability in acetonitrile as compared to e.g., methanol. Hexane can be removed by the addition of 5 ml acetonitrile for each ml of extract and subsequent evaporation to 1–2 ml. Azeotropic evaporation leaves only acetonitrile. During solvent exchange, evaporation to dryness should be avoided.

Azeotropic exchange can also be applied the other way around. In that case, 5 ml hexane must be added for each ml of acetonitrile.

For GC methods, *iso*-octane or toluene are suitable solvents for injection and can be added as keeper before evaporation to the required volume.

6. Chromatographic determination

The separation of PAHs should be optimized for at least the compounds listed in Annex B-13 (Appendix 1, Table 1) (Keith and Telliard, 1979). Separation should not only be optimized for a standard solution but also for a sample, as samples often contain several non-target PAHs that should be separated from the target compounds, if possible. In addition, sample extracts can be affected by remaining matrix effects, despite clean-up.

Basically and in particular for the parent PAH both HPLC-Fluorescence and GC-MS analyses are considered to be equally valid methods. However, with respect to the alkylated PAH species satisfactory analysis is often not obtained using HPLC. This is particularly relevant as alkylated PAH compounds are of increasing interest. Therefore, use of GC-MS analysis is recommended.

Table 1 Compounds of interest for environmental monitoring for which the guideline applies.

Compound	**MW**	**Compound**	**MW**

Naphtalene	128	Fluoranthene	202
C1-Naphtalenes	142	Pyrene	202
C2-Napthalenes	156	Benzo[a]anthracene	228
C3-Napthalenes	170	Chrysene	228
Acenaphthylene	152	Benzo[a]pyrene	252
Acenaphthene	154	Perylene	252
Fluorene	166	Indeno[1,2,3-cd]pyrene	276
Phenanthrene	178	Benzo[k]fluoranthene	252
Anthracene	178	Benzo[ghi]perylene	276
C1-Phenanthrene/Anthracene	196	Dibenzo[ah]anthracene	278
C2-Phenanthrene/Anthracene	206		
C3-Phenanthrene/Anthracene	220		

6.1 High performance liquid chromatography

For HPLC analysis of PAH, a binary gradient is necessary to achieve proper compound separation.

Using HPLC and measuring concentrations with the peak height, a 50 % valley should be considered as adequate separation.

Solvents should be degassed through an online degassing system in order to allow proper operation of the high pressure pump. Sample injection should be carried out with an autosampler. In addition, a thermostated column compartment (10–30 °C) should be used as retention time and resolution can be affected by varying the temperature.

6.1.1 Columns

The column specifications are:

- stationary phases: e.g., octadecylsilane (RP-18), or special PAH column material;
- length: 15–25 cm;
- inner diameter: 4.6 mm or less;
- particle size: 5 µm or less.

If the dimensions of the detector cell and the tubings are appropriate, columns with diameters smaller than 4.6 mm can be chosen in order to reduce the flow of the eluent and, thus, to save solvent. In this case the amount of sample injected should also be reduced to e.g. 25–50 µl for a 4.6 mm column or 10 to 20 µl for a 3 mm column.

6.1.2 Gradient Elution

For elution, e.g. methanol/water or acetonitrile/water can be applied. The use of acetonitrile allows higher flow rates, with the disadvantage of having higher health risks than methanol.

A typical elution gradient with a flow rate of 1–1.5 ml min-1 for a 4.6 mm column is:

- start at initially 50 % methanol/water or acetonitrile/water

- run to 100 % methanol or acetonitrile in 40 minutes
- remain for 20 minutes
- back to the initial conditions for about 5 minutes
- equilibrium time of about 5 to10 minutes (3–5 times the dead volume) prior to the next injection,

100 % methanol or acetonitrile may not be sufficient to elute all non-target compounds from the column. In this respect, a further elution step using acetone/methanol (1/1) or acetonitrile/acetone (1/1) can be applied. A ternary gradient is then necessary.

In order to obtain reproducible retention times, the equilibrium time after each run should be constant. Therefore, automatic injection is strongly recommended.

6.1.3 Detection

For the detection of PAHs, the more sensitive and selective fluorescence detector is preferred over a UV detector. The excitation and emission wavelengths should be programmable to allow the detection of PAHs at their optimum wavelength (Reupert and Brausen, 1994; ISO, 1995).

However, when PAHs elute close to each other, wavelength switching cannot be carried out between these peaks and a wavelength pair appropriate for the respective compounds has to be chosen. The use of two detectors in series, or running the analysis twice with different wavelength programmes, can minimize the need for such compromises.

As the fluorescence signals of some PAHs can decrease by up to a factor of ten in the presence of oxygen, the eluents must be degassed thoroughly. Therefore, instruments with online degassing systems are strongly recommended. In addition, PTFE tubings should not be used as this material is permeable to oxygen and allows oxygen to enter the system again. The use of stainless steel or PEEK (polyetheretherketone) tubing is recommended.

Acenaphthylene is not detectable with fluorescence and, therefore, a UV or diode-array detector should be used for detection.

Another possible detection technique is mass spectrometry, where isotopically labeled compounds are used as internal standards.

6.1.4 Identification

The individual PAHs are identified by comparing the retention time of the substance in a sample with that of the respective compound in a standard solution analyzed under the same conditions. It is recommended to confirm the results by using other suitable wavelength for UV-absorption or excitation and emission wavelengths for fluorescence detection.For HPLC analysis, reproducibility of retention times should be within ±1 minute.

6.2 Gas chromatography

6.2.1 Columns

Column dimensions for the determination of PAHs should be the following:

- length: minimum 25 m;
- inner diameter (i. d.): maximum 0.25 mm;
- film thickness: between 0.2 µm and 0.4 µm;
- stationary phases: A wide range of non-polar or slightly polar stationary phases can be used for the separation of PAHs, e.g., a 5 % phenyl-substituted methyl polysiloxane phase.

Better resolution can be obtained by increasing the length and reducing the inner diameter to 0.20 mm or less. However, below a diameter of 0.15 mm, the carrier gas pressure rises to values above 500 kPa, which are often not compatible with regular GC equipment. Also, the risk of leakages increases.

6.2.2 Carrier gas

Preferentially, helium should be used as carrier gas for GC-MS. Upon using columns with very small inner diameters, the use of hydrogen is essential.

The linear gas velocity should be optimized. Appropriate settings for 0.25 mm i.d. columns range from 20 to 40 cm s^{-1} and for 0.15 mm i.d. columns from 30 to 50 cm s^{-1}.

6.2.3 Injection techniques

Sample injection should be carried out with an autosampler. The two systems commonly used are splitless and on-column injection. Other techniques such as temperature-programmed or pressure-programmed injection may have additional advantages, but should be thoroughly optimized before use. Due to their high boiling points, on-column injection is recommended for separation of the PAH compounds.

6.2.4 Temperature programming

The temperature program must be optimized for sufficient separation of the PAH compounds. For GC-MS analysis peak areas are generally used and a 10 % valley would represent a good separation. Less resolved peaks may also be quantified - e.g. by dropping perpendiculars to the baseline-, but increasing errors may result.

In addition to a reproducible temperature program, a fixed equilibration time is important for a correct analysis and constant retention times.

6.2.5 Detection

The most frequently used detector for GC analysis of the PAH compounds is a mass spectrometric detector operating in the Selected Ion Monitoring (SIM) mode and with electron impact ionization (EI) as the ionization method. The selectivity of a mass spectrometric detector is excellent and the chromatographic noise of a standard is similar to that of a sample. However, major drawbacks are the matrix-dependent response and the convex calibration curves that both often occur and make quantification difficult which, however, can be overcame with tandem mass spectrometry (GC-MS/MS).

Another technique for PAH identification is the full-scan MS using an ion trap operating with the same sensitivity as SIM, but in full scan to give the best detection limits and compound identification for methylated PAHs, compared to quadrupole MS with multiple ion monitoring mode (Law et al, 2011). The use of a flame ionization detector (FID) is also possible, but since the selectivity of the FID is low, it is not recommended. In addition, isotopically labeled internal standards (see 8.5) cannot be used in combination with a FID.

6.2.6 Identification

For GC-MS analysis the presence of the characteristic mass fragments or mass transitions (GC-MS/MS) prove the presence of the particular PAH compound. Retention times should be reproducible within ±0.05 minutes.

7. Quantification

Automatically processed chromatograms should be reviewed if, e.g., the baseline is set correctly. Because the separation of the peaks is often incomplete in HPLC analysis, the use of peak heights is recommended for quantification. In case of GC techniques, the use of peak areas is recommended.

For calibration purposes a multilevel calibration with at least five concentration levels is recommended. The calibration curve should be linear and cover the working range. Usually, the response of FID, UV and fluorescence detectors exhibit linearity over a large range.

Since mass spectrometric detectors often lack sufficient linear response, the use of stable isotopes is a prerequisite. Furthermore, the response of PAHs in standard solutions is often much lower than in sample extracts. A combination of different methods, e.g., use of internal standards and standard addition, might give quantitative results.

Obtained calibrations should be regularly validated in terms of precision and accuracy.

Prior to running a series of samples and standards, the GC or HPLC systems should be equilibrated by injecting at least one sample extract. In addition, standards used for multilevel calibrations should be regularly distributed over the sample series so that matrix-and non-matrix-containing injections alternate. A sample series should include:

- a procedural blank;
- a laboratory reference material;
- at least five standards;
- one standard sample treated similarly to the samples for determination of the recovery.

The method for calculating the limit of determination should reflect the advice in Part B-4.2.3 (COMBINE manual).

The limit of quantification usually depends on the purpose of the investigation. The limit of quantification that can be achieved depends on the blank sample, the sample matrix, concentrations of interfering compounds, and the amount of sample. However, a limit of quantification of 2 ng g^{-1} (dry weight) or better should be attained for single compound analysis.

8. Quality Assurance

A number of measures should be taken to ensure sufficient quality of the analysis. Six main areas can be identified:

1. extraction efficiency and clean-up;
2. calibrant and calibration;
3. system performance;
4. long-term stability;
5. internal standards; and
6. Frequent participation in interlaboratory proficiency testing schemes (e.g. QUASIMEME two times a year, www.quasimeme.org).

8.1 Extraction efficiency and clean-up

Extraction efficiency and clean-up can be controlled by analysing reference materials (Annex B-7). To determine the recovery rates of the clean-up and concentration steps, it is recommended to pass a standard solution (see 8.5. INTERNAL STANDARDS) through the entire procedure. The addition of corresponding internal standards to the samples is preferred.

If major losses have occurred, the results should not be reported.

8.2 Calibrant and calibration

Basically, calibration solutions should be stored in ampoules at a cool, dark place. Weight loss during storage should be recorded for all standards.

For PAH determination preferentially calibration solutions from certified crystalline PAHs should be used. However, the laboratory should have the appropriate equipment and expertise to handle these hazardous crystalline substances. Alternatively, certified PAH solutions can be used. Preparation of two independent stock solutions allows cross-checks of the standard solutions if necessary.

8.3 System performance

The performance of the HPLC or GC system can be monitored through regularly analyzing the resolution of two closely eluting PAHs or chlorinated biphenyl compounds. A decrease in resolution indicates deteriorating HPLC or GC conditions.

The signal-to-noise ratio of a low concentrated standard can give information on the condition of the detector. For example, a dirty MS-source can be recognized by the presence of a higher background signal, together with a reduced signal-to-noise ratio if not used in the SIM mode.

8.4 Long-term stability

One laboratory reference sample should be included in each series of samples. A quality control chart should be recorded for selected PAH compounds, e.g., fluoranthene (stable results), pyrene (sensitive to quenching), benzo[a]pyrene (sensitive to light). If warning limits are exceeded, the method should be checked for possible errors and the obtained sample results should not be reported.

If available, a certified reference material (CRM) should be analysed regularly and in particular, if the procedure was changed.

8.5 Internal standards

Internal standards should be added to all standards and samples either in a fixed volume or by weight and should not interfere with the target analytes.

A number of deuterated PAH compounds were proven to be suitable for GC-MS as well as for HPLC analysis. For GC-MS analysis it is recommended to have internal standards corresponding to each analyte, e.g. by using isotopically labeled compounds. Otherwise, at least four internal standards representing the different ring-sizes of the PAH compounds should be added.

The following compounds can be used (Wise et al., 1995):

- for HPLC analysis: phenanthrene-d10, fluoranthene-d10, perylene-d12, 6-methyl-chrysene;
- for GC-MS analysis: naphthalene-d8, phenanthrene-d10, chrysene-d12, perylene-d12;
- for GC-FID analysis: 1-butylpropylene, m-tetraphenyl

After clean-up and before GC analysis, an additional internal standard can be added to evaluate the recovery of the internal standards added before clean-up.

8.6 Interlaboratory proficiency testing schemes

Each laboratory analysing sediments should participate in interlaboratory studies on the determination of PAH in sediments on a regular basis (e.g. QUASIMEME offers the possibility to take part twice a year, www.quasimeme.org).

Monitoring Guidelines/Protocols for Sampling and Sample Preservation of Marine Biota for IMAP Common Indicator 17: Heavy and Trace Elements and Organic Contaminants

1. Introduction

1. Heavy metals and organic contaminants are entering the Mediterranean marine environment discharged from land-based and sea-based pollution sources, as well as from atmospheric deposition. The UNEP/MAP Integrated Monitoring and Assessment Programme (IMAP) (UNEP/MAP, 2019a[250]; UNEP (2019b[251]) includes the analysis of specific sedentary marine sentinel organisms (bivalves and benthic feeding fish) in order to assess pollution impact on the marine organisms. The suggested species for monitoring contaminants are a benthic feeding fish (e.g. *Mullus barbatus*) and bivalves (e.g. *Mytilus galloprovincialis*, *Donax trunculus*). However, in case different species of fish and bivalves are used by the Contracting Parties to the Barcelona Convention for assessing marine pollution, explanation has to be provided to UNEP/MAP Secretariat on the reason behind the selection of a different sentinel species for CI17 monitoring.

2. Standardize protocols for sampling and processing of marine biota samples is important in view of assuring comparable quality assurance of the data, as well as comparability between sampling areas and different national monitoring programmes. Also, sampling protocols provide guidance on the suitability of selected sampling sites, the number of required samples, the biometric indices to be recorded, the appropriate handling to avoid cross-contamination, and the storage conditions in view of maintaining the sample's integrity during the transfer from the sampling site to the analytical laboratory. Furthermore, protocols are providing guidance on the procedures to dissect the organisms (fish and bivalves) in order to collect the appropriate tissue for analysis (muscle and liver of fish and whole body of bivalves), taking care to avoid cross-contamination by metals or organic contaminants, depending on the foreseen analysis.

3. The Protocols on of this Guidelines, as provided here-below aim at streamlining sampling and processing of marine biota samples in view of assuring comparable quality assurance of the data, as well as comparability between sampling areas and different national monitoring programmes. They also provide the guidance on the suitability of selected sampling sites, the number of required samples, the biometric indices to be recorded, the appropriate handling to avoid cross-contamination, and the storage conditions in view of maintaining the sample's integrity during the transfer from the sampling site to the analytical laboratory to ensure the representativeness and the integrity of the samples. Furthermore, they guide on the procedures to dissect the organisms (fish and bivalves) in order to collect the appropriate tissue for analysis (muscle and liver of fish and whole body of bivalves), taking care on a need to avoid cross-contamination by metals or organic contaminants, depending on the foreseen analysis. They are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories, which should be tested and modified in order to validate their final results.

4. In order to avoid unnecessary repetitions, reference is also made to the protocols already published and publicly accessible, which can also be used by the Contracting Parties' competent laboratories participating in IMAP implementation. Namely, the six here-below elaborated IMAP Protocols build on previous UNEP/MAP - IAEA Recommended Methods, such as Reference Methods No 6 on sampling of selected marine organisms and sample preparation for trace metal analysis (UNEP/FAO/IOC/IAEA, 1987, Annex I) and Reference Methods No 7 (Rev. 2) on sampling and dissecting marine organisms (UNEP/FAO/IOC/IAEA, 1988, Annex II), which were prepared in the framework of the MED POL monitoring programme. IMAP Protocols are also streamlined with similar Guidelines/Protocols for marine biota sampling, sample processing and preservation, which were developed by other Regional Seas Organisations, such as HELCOM (2012[252]) (Annex III) and ICES/OSPAR (2018[253]) (Annex IV) as well as the European Commission's guidance documents (EC

[250] UNEP/MAP (2019a). UNEP/MED WG.467/5. IMAP Guidance Factsheets: Update for Common Indicators 13, 14, 17, 18, 20 and 21: New proposal for candidate indicators 26 and 27

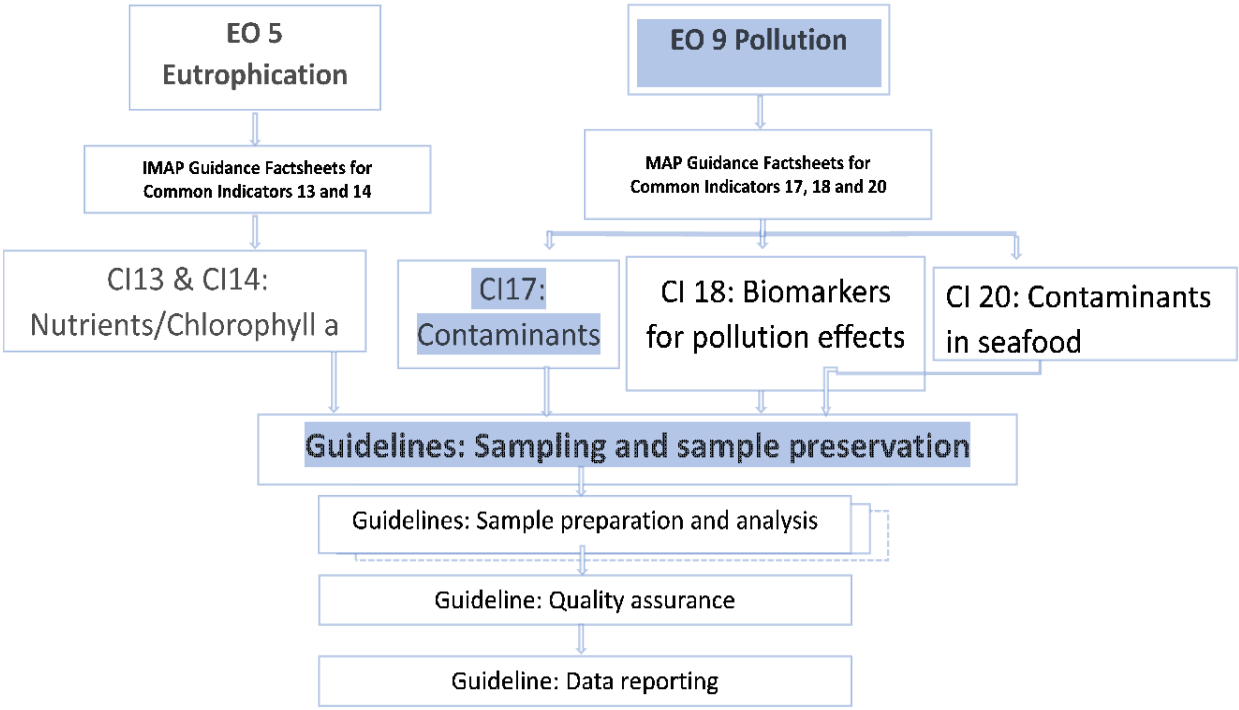
[253] ICES/OSPAR (2018). CEMP Guidelines for Monitoring Contaminants in Biota

2010[254] and 2014[255]). Given the suitability of any of these Guidelines in the context of IMAP, they could be further used by interested IMAP competent Mediterranean laboratories for developing their laboratory specific sampling and sample processing methodologies.

5. The below flow diagram informs on the category of this Monitoring Guideline related to sample preparation and analysis of marine biota for IMAP Common Indicator 17 within the structure of all Monitoring Guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.



Flow Diagram: Monitoring Guidelines for IMAP Ecological Objectives 5 and 9

2. Technical note for the sampling of marine biota for the analysis of heavy metals and organic contaminants

6. Sampling is a very important step in the analysis of marine biota, since it affects the representatives of the sample, which is the basis of every Quality Assurance scheme. The fish and bivalves collected should reflect the condition of other organisms of the same species in the marine area under consideration. The sampling location and conditions (including seafloor nature, sampling depth, location of pollution sources) have to be chosen carefully, taking into consideration other oceanographic data (such as temperature, turbidity, trophic level) in the sampling area. The handling of biota after collection is also of primary importance, in order to follow appropriate procedures to avoid cross contamination of the samples from the ship's environment and the storage of samples. Also, the appropriate preservation of samples during transportation from the sampling site to the laboratory for further analysis is crucial, in order to avoid the deterioration of the biota tissues that may result in loss of determinant or contamination from the packaging materials. Finally, once the biota samples arrive at the laboratory, additional processing is required to dry and homogenize the samples and to store the

[254] EC (2010). Guidance Document No: 25 Guidance on chemical monitoring of sediment and biota under the Water Framework Directive
[255] EC (2014). Guidance Document No: 32 Guidance on biota monitoring under the Water Framework Directive

dried samples in appropriate conditions in order to avoid any alteration of the contaminants' concentrations in the samples.

7. Under this Technical Note, this Guidelines for Sampling and Sample Preservation of Marine Biota for IMAP Common Indicator 17 provides the following Protocols:

- Protocol for the collection of fish for heavy metal and organic contaminants analysis;
- Protocol for the collection of bivalves for heavy metal and organic contaminants analysis;
- Protocol for the dissection of fish to collect muscle and liver;
- Protocol for the dissection of bivalves.

2.1 Protocol for the collection of fish for heavy metal and organic contaminants analysis

8. The most common fish species used for marine pollution monitoring in the Mediterranean region is the mullet (*Mullus barbatus*) (UNEP, 2019b). However, in different areas, according to local conditions, other benthic fish may be used for monitoring contaminants. A list of available reference species (Code list) for Data Dictionaries and Data Standards of the IMAP (Pilot) Info System for E09 (CI17 and CI20) is presented in the document UNEP/MED WG.467/8 (UNEP, 2019c[256]).

9. For fish sampling, in line with the IMAP Monitoring Protocols for CI17 (UNEP, 2019b), 3-5 parallel composite samples (5-6 specimen for each fish sample) are collected from the same size class at each site. During the initial phase of the IMAP (identification of key sampling sites/stations) fish sampling should be done every 4 years and bivalves sampling yearly, while during the advanced phase (when it is a fully completed MED POL Phase IV implementation with the ongoing reporting of data sets) biota sampling should be done every 1 to 3 years, according the trends and levels assessed at the different stations/sites (UNEP, 2019a). EU requests Member States to determine the frequency of monitoring in sediment and/or biota so as to provide sufficient data for a reliable long-term trend analysis (2008/105/EC[257]). As a guideline, the Directive suggests a monitoring frequency of three years for sediment and biota, unless technical knowledge and expert judgment justify another interval.

10. Fish having a length of 12-16 cm should be included if possible in the selected size classes, to be in line with the Protocol for fish collection for the CI18. Fish can be collected by gill net fishing or trawling using a square-meshed net of 40 mm or, if justified, by a diamond meshed net of 50 mm as required by the EU legislation (EC 1967/2006[258]). Guidelines for collection of fish are presented in UNEP/FAO/IOC/IAEA (1987) (Annex I) and UNEP/FAO/IOC/IAEA (1988) (Annex II). Fish could be sampled from a research vessel or from a small fishing boat. Guidelines on sampling and processing of fish samples are also provided by HELCOM (2012) (Annex III.) and OSPAR (2018).

11. It has to be underlined that concentrations of chemical pollutants in marine biota tissues can be influenced by many environmental factors (such as seasonal fluctuations of temperature, organic matter, nutrients) and biological factors (such as the phase of reproductive cycle, weight fluctuations, changes in relative tissue composition, the massive development of gonadic tissues during gametogenesis and the loss of weight during spawning). In order to avoid such variations, it is recommended that sampling take place in the off-spawning period (EC. 2010). Also, in order to evaluate the influence of common biological and environmental factors it is suggested to record the date, seawater temperature, salinity, phytoplankton development, at sampling time.

12. Fish samples should be protected from contamination, which may occur during sampling, sample handling, storage and transfer to the laboratory for further analysis. In case fish are dissected on board, the work must be carried out by personnel capable of identifying and removing the desired

---

[256] UNEP (2019c) UNEP/MED WG.467/8. Data Standards and Data Dictionaries for Common Indicators related to pollution and marine litter.

[257] EC Directive 2008/105/EC (2008) on environmental quality standards in the field of water policy, amending and subsequently repealing Council Directives 82/176/EEC, 83/513/EEC, 84/156/EEC, 84/491/EEC, 86/280/EEC and amending Directive 2000/60/EC of the European Parliament and of the Council

[258] EC Council Regulation No 1967/2006 concerning management measures for the sustainable exploitation of fisheries resources in the Mediterranean Sea

organs according to the requirements of the investigation. Fish samples have to be handled with care to avoid any contact with metals (for heavy metal analysis) or possible sources of organic contaminants (for chlorinated hydrocarbons and PAHs analysis). Detailed procedures for fish dissection and the measures to be taken in order to avoid sample contamination during handling, are presented in Protocol for the fish dissection to collect muscle and liver. Upon fish collection additional information on length, wet weight and sex should be recorded. In case of pooling, number of specimens and length range should also be recorded.

13. In case fish samples have to be transported to the laboratory for dissection, they have to be handled and stored in such a way, as to avoid sample deterioration or contamination. A ship has several potential metal contamination sources (metallic hull and superstructures, paint). To prevent metal contamination fish samples intended for heavy metal analysis should be handled in metal-free areas (working surfaces with plastic coatings or cover) and stored in plastic bags for transport to the laboratory. Regarding PAHs and chlorinated hydrocarbons, possible contamination sources in a ship include fuel and lubrication, as well as exhaust from the ship's engines. Fish samples intended for organic contaminants analysis have to be stored in metal containers for their transport to a stainless steel of aluminium clean working surface in the ship's laboratory. Before starting the handling of fish samples, it is important to identify possible contamination sources in the ship and the samples handling area, in order to take appropriate measures to avoid contamination.

14. In case fish transport to the laboratory is done in less than 24 hours, samples can be stored on ice. However, for longer periods, fish samples have to be frozen (-20 ^{o}C) and transported frozen to the laboratory for further processing. Each sample should be labelled with the sample's identification number, the type of tissue, and the date and location of sampling.

2.2 Protocol for the collection of bivalves for heavy metal and organic contaminants analysis

15. *Mytilus galloprovincialis* and *Donnax trunculus* are the bivalve species suggested to be analysed for heavy metals and organic contaminants in the framework of CI17 (UNEP/MAP, 2019; UNEP/MAP 2019a). If the Contracting Party decides to analyse other bivalve species, it has to provide UNEP/MAP the rationale behind its decision. To facilitate reporting a list of available reference species (Code list) is provided in the document UNEP/MED WG.467/8 (UNEP, 2019c).

16. In line with the IMAP Monitoring Protocols for CI17 (UNEP, 2019b), 3-5 parallel composite samples of bivalves (10 specimens for each bivalves sample) are collected yearly from the same size class at each trend monitoring. Minimum bivalves sampling is once per year, although twice per year may be applied if possible to be in line with CI18 sampling frequency. The most adequate sampling period is during the post winter months, but before the spawning period. Usually, in most Mediterranean coastal areas, April-June is an appropriate sampling period, but local climatic characteristics have to be taken into consideration for the fixing of the sampling period.

17. The bivalves' size to be collected should be 4-5 cm, to be in line with the sampling protocol for CI18. However, a length-stratified sampling could be applied, which is generating data that can also be used in monitoring programmes for temporal trends of contaminants in biota (HELCOM, 2012). The HELCOM methodology requires that at least 20 mussels in the largest length interval can easily be found and the length stratification should be determined in such a way that it can be maintained over many years for the purposes of temporal trend monitoring. It is also requiring that the length interval shall be at least 5 mm in size. The length range should be split into at least three length intervals (small, medium, and large) which are of equal size after log transformation and the number of specimens selected for analysis depends on their length, e.g. 80-100 individuals are necessary to suffice material within the length range 4-5 cm (HELCOM, 2012).

18. Bivalves sampling sites should host an abundant population of the targeted species in order to take appropriate size of sample and to be reasonably accessible in order to easily and rapidly transport biota samples to the laboratory. Bivalves growing on metal structures (i.e. underwater pipes) or substrates, which may be enriched in metals or organic contaminants, should be exempted from collection. Divers will collect manually the mussels living at a 4-5 m under the water surface. Mussel

byssus threads should be cut from the substrate, since pulling the animals from the rocks (threading) can result in damage to internal tissues. Using mussels living at the water/air interface, the physical contamination by lipophilic contaminants present on the water surface may alter the evaluation of the chemical's content in mussel soft tissues.

19. Detailed guidelines for bivalves' collection for analysis and samples processing are presented in the recommended methods developed by UNEP/FAO/IOC/IAEA (1987) (Annex I) and UNEP/FAO/IOC/IAEA (1988) (Annex II). Also, similar guidelines are published by HELCOM (2012) (Annex III) and OSPAR (2018) (Annex IV).

20. In places were no wild bivalves populations are found, caged bivalves can be used as an alternative option for monitoring (UNEP, 2019b). Adult mussels (4-5 cm) are collected from a mussel farm, transported to the marine area under investigation and re-immersed for 10 days to permit them to re-cluster and reduce mortality risk during transplantation at the sampling site. Then cages with mussels are transported to the sampling site, where cages are suspended at 6m to 8m from the sea surface, anchored at the bottom with a 30 kg ballast, and exposed for 12 weeks. During recovery of cages, the biometric parameters shell height and wet weight (w.w.) of soft tissues are measured at least in 15 mussels per each cage. Details on the protocol for using caged bivalves in monitoring heavy metals and organic contaminants in the marine environment are presented in Galgani et al. (2011)[259] and Galgani et al (2014)[260].

21. The undamaged bivalves are transported to the laboratory moist and alive in appropriate closed containers to avoid contamination (i.e. plastic containers for organisms to be analysed for heavy metals and metals containers for organisms to be analysed for chlorinated hydrocarbons and PAHs), at temperatures between 5 °C and 15 °C (24 hours is the maximum transport time in these conditions). Bivalves should be kept moist using clean seawater from the sampling site without submerging them. For a transportation time of more than 24 hours, bivalves should be placed in appropriate container and frozen. Frozen, samples can be stored in a deep freezer at temperatures of -20ºC. Each sample should be labelled with the sample's identification number, the type of tissue, and the date and location of sampling.

2.3 Protocol for the dissection of fish to collect muscle

i) Dissection

22. Muscle tissues of fish has to be dissected while the organism is in good condition, otherwise the decay of the tissues will affect the concentration of contaminants. Therefore, it is preferable to dissect collected fish on board, by experienced personnel able to perform the dissection and remove the fish tissues to be analysed (muscle and liver). The on-board dissection should be done in a clean area free from possible contamination of the sample by metals or organic contaminants respectively. If no on-board dissection capability is available (because of lack of experienced personnel and/or lack of adequate clean dissection area), collected fish should be transferred to the laboratory taking care to prevent tissue decay. If the laboratory is reachable within 24 hours, fish could be preserved on ice during the transfer. For longer periods, fish should be frozen immediately and transferred frozen to the laboratory, where they will be thawed before dissection.

---

[259] Galgani, F., Martínez-Gómez, C., Giovanardi, F., Romanelli, G., Caixach, J., Cento, A., Scarpato, A., BenBrahim, S., Messaoudi, S., Deudero, S., Boulahdid, M., Benedicto, J., Andral, B. (2011). Assessment of polycyclic aromatic hydrocarbon concentrations in mussels (Mytilus galloprovincialis) from the western basin of the Mediterranean Sea. Environ. Monit. Assess. 172 (1–4), 301–317. https://doi.org/10.1007/s10661-010-1335-5.

[260] Galgani, F., Chiffoleau, J.F., Barrah, M., Drebika, U., Tomasino, C., Andral, B. (2014). Assessment of heavy metal and organic contaminants levels along the Libyan coast using transplanted mussels (Mytilus galloprovincialis). Environ. Sci. Pollut. Res. 21, 11331–11339. https://doi.org/10.1007/s11356-014-3079-1.

23. Detailed guidelines for the dissection of fish and collection of samples for further analysis is presented in the UNEP/FAO/IOC/IAEA Reference Method No 6 (1987) (Annex I.) and UNEP/FAO/IOC/IAEA Reference Method No 7 (1988) (Annex II).

24. HELCOM (2012) and OSPAR (2018) propose a similar procedure for fish dissection and removal of muscle for further analysis. The method requires the removal of the epidermis and the collection of a sample from the right side dorso-lateral muscle in order to ensure uniformity of samples (Figure 1). It is also suggested to take the entire right dorsal lateral filet as a uniform sample, from which subsamples can be taken after homogenizing for replicate dry weight and contaminant determinations. If the amount of material obtained by this procedure is too large to be easily handled, a specific portion of the dorsal musculature should be chosen for the sample. It is recommended that the portion of the muscle lying directly under the first dorsal fin should be utilized in this case. It is important to obtain the same portion of the muscle tissue for each sample, because both fat and water content vary significantly in the muscle tissue from the anterior to the caudal muscle of the fish.

25. In case fish samples are frozen for their transfer from the field to the laboratory, they have to rest until thawed. It is often suggested that the dissection of fish is easiest when the material, at least the surface layers of the muscle tissue, is half frozen. Extreme care has to be demonstrated during dissection because any loss of liquid or fat due to improper cutting or handling of the tissue makes the determinations of dry weight and fat content less accurate, which is also affecting the accuracy of the reported contaminants' concentrations.

26. In all cases fish dissections should be undertaken by trained personnel.

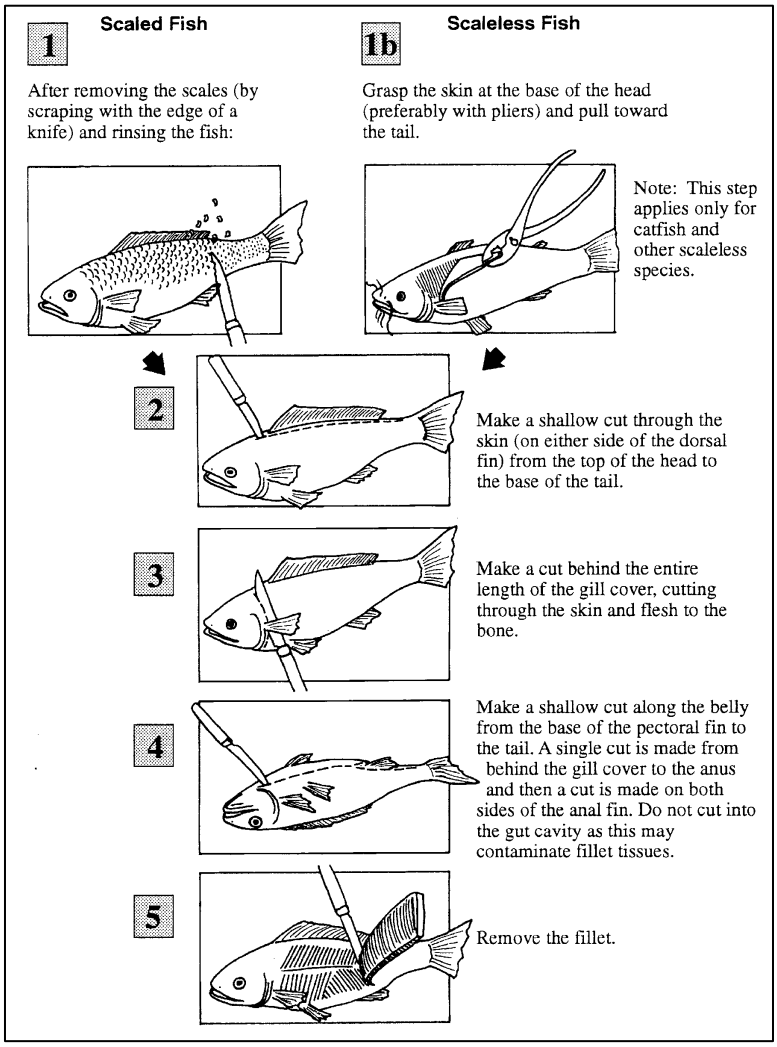


Figure 1. Fish filleting procedure (from US EPA, 2000[261])

27. In case liver tissue is sampled for analysis (not a mandatory tissue in the framework of IMAP), HELCOM guidelines underline that "the liver must be identified in the presence of other organs such as the digestive system or gonads. After opening the body cavity with a scalpel, the connective tissue around the liver should be cut away and as much as possible of the liver is cut out in a single piece together with the gall bladder. The bile duct is then carefully clamped and the gall bladder dissected away from the liver."

b) Avoiding contamination

28. For metal analysis, handling of fish should be made on a metal-free bench, using plastic knives and tweezers for holding tissues during dissection. After each sample has been prepared, all tools and equipment (such as homogenizers) should be cleaned.

29. For organic contaminants analysis, handling of fish should be made on a metallic (stainless steel or aluminium) bench, using stainless steel knives and tweezers for holding tissues during dissection. After each sample has been prepared, all tools and equipment (such as homogenizers) should be cleaned.

[261]US EPA (2000). Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories Volume 1 Fish Sampling and Analysis. Third Edition.

30. After the removal of a tissue sample from a fish, the tools have to be cleaned before being used to remove another organ (i.e. liver) of the same individual or being used on a different individual.

31. HELCOM (2012) recommends the following procedures for cleaning tools used for preparing samples:

For analysis of heavy metals, tools should be:

i) Washed in acetone or alcohol and high purity water.

ii) Washed in HNO_3 diluted (1+1) with high purity water. Tweezers and haemostates should be washed in diluted (1+6) acid.

iii) Rinsed with high purity water.

For analysis of organochlorine pesticides

i) Washed in acetone or alcohol and rinse in high purity water.

32. The glass plate used during dissection should be cleaned in the same manner. The tools must be stored in a dust-free area when not in use. Also, the dissection room should be kept clean and the air should be free from particles. If clean benches are not available on board the ship, the dissection of fish should be carried out in the land-based laboratory under conditions of maximum protection against contamination.

2.4 Protocol for the dissection of bivalves

a) Depuration

33. Collected bivalves should be left to void the gut contents and any associated contaminants before freezing or sample preparation, because gut contents may contain significant quantities of contaminants associated with food and sediment particles which are not truly assimilated into the tissues of the mussels (HELCOM, 2012). Bivalve's depuration over a period of 24 hours is usually sufficient and should be undertaken under controlled conditions and in filtered sea water in the laboratory. The aquarium should be aerated, and the temperature and salinity of the water should be similar to that from which the animals were removed.

b) Bivalve dissection

34. According to the UNEP (2019b) UNEP/MED WG.463/6. Monitoring Protocols for IMAP Common Indicators related to pollution, the whole soft tissue of bivalves has to be collected for analysis. Detailed guidelines for the dissection of fish and collection of samples for further analysis is presented in the UNEP/FAO/IOC/IAEA Reference Method No 6 (1987) (Annex I) and UNEP/FAO/IOC/IAEA Reference Method No 7 (1988) (Annex II). Guidelines for sampling and processing of bivalves is also prepared by HELCOM (2012) (Annex III) and OSPAR (2018) (Annex IV).

35. In general, foreign materials attached to the outer surface of the shell have to be removed using a clean plastic/stainless steel knife and a strong plastic/metal brush. Handle the mussels as little as possible. Rinse each mussel with clean seawater and let the water drain off. Then pull out the byssus which extrudes from between the closed shells on the concave side of the shells; weigh the whole mussel and note the weight.

36. For removing the soft tissue for analysis, bivalves should be shucked live and opened with minimal tissue damage. Insert a clean plastic/stainless steel knife into the opening from which the byssus extrudes and cut the adductor muscles. Avoid forcing the mussel to open, if the abductor muscle is cut, the bivalve will open easily (Figure 2). Rinse the soft part of the mussel in its shells with clean seawater. The soft tissues should be removed and homogenized as soon as possible, frozen and kept in plastic containers (for metal analysis) or in metal containers at -20°C until analysis. Homogenization can be done using stainless steel blades (for organic contaminants analysis) or using an agate mortar, following the drying of the sample.

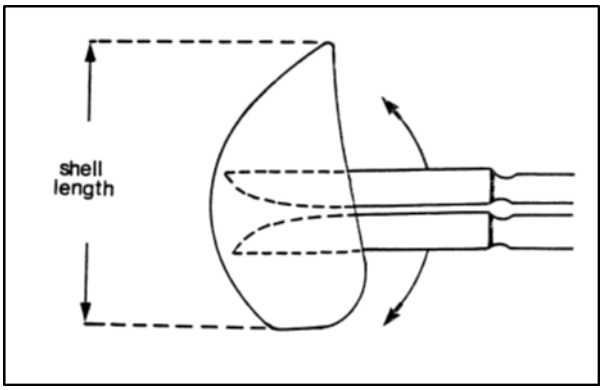

Figure 2. Cutting the abductor muscle

37. For metal analysis, the handling of bivalves should be made on a metal-free bench, using plastic knives and tweezers for holding tissues during dissection. After each sample has been prepared, all tools and equipment (such as homogenizers) should be cleaned with a tissue and rinsed with clean water.

38. For organic contaminants analysis, the handling of bivalves should be made on a metallic (stainless steel or aluminium) bench, using stainless steel knives and tweezers for holding tissues during dissection. After each sample has been prepared, all tools and equipment (such as homogenizers) should be cleaned with tissue and rinsed with solvent

39. In all cases bivalve dissection should be undertaken by trained personnel.

3. Technical note for the sample preservation of marine biota for the analysis of heavy metals and organic contaminants

40. Once the biota samples arrive at the laboratory, additional processing is required to dry and homogenize the samples and to store the dried samples in appropriate conditions. During the processing of the samples it is important to avoid any cross contamination (metal or organic contaminants) from the equipment and the containers used to store the dried samples. Analysis may be performed at a later stage, it is therefore important to avoid any alteration of the contaminants' concentrations in the samples during storage.

41. Under the Technical Note, this Guidelines for Sampling and Sample Preservation of Marine Biota for IMAP Common Indicator 17 provides the following Protocols:

- Protocol for the treatment of biota samples prior to analysis of heavy metals;
- Protocol for the treatment of biota samples prior to analysis of organic contaminants.

3.1 Protocol for the treatment of biota samples prior to analysis of heavy metals

a) Storage of wet samples on board

42. Upon collection wet samples have to be stored on board in such a way as to preserve them from deterioration that will affect the subsequent analysis of contaminants. When the fish transport to the laboratory is done in less than 24 hours, samples can be stored on ice. However, for longer periods, fish samples have to be frozen (-20 ºC) and transported frozen to the laboratory for further processing. Each sample should be labelled with the sample's identification number, the type of tissue (if already dissected), and the date and location of sampling.

b) Drying of biota tissues

43. Drying biota tissues is a procedure to establish the dry/wet weight (dw/ww) ratio of the tissues, in order to express metal concentrations accordingly enabling comparisons between different data sets. Dried biota tissues can then be digested for heavy metal analysis. For metal (except volatile mercury)

analysis, biota freeze-drying is the preferable procedure. Alternatively, the biota tissues may be dried at any temperature below 105°C until constant weight. For mercury analysis, to minimise losses due to evaporation, a biota tissue sub sample could be air dried at temperature <50°C (EC, 2010).

44. Frozen biota samples are placed in clean wide-mouth glass or plastic containers suitable for freeze-drying and are freeze-dried for 24 hours taking care to protect them from cross-contamination from particles and vapours. A possible way to protect samples from contamination is to cover the sample containers with a filter paper perforated with a small hole (HELCOM, 2012). Then the containers with the samples are weighted and freeze-dried again for another 24 hours and weighted. If the difference between the 2 weighing is less than 0.5%, drying is completed and the dw/ww ratio can be calculated. Otherwise the drying cycle can be repeated (24 hours) until the difference between successive weighing is less than 0.5%.

45. Freeze dried biota tissues are then grinded and homogenized using a metal-free ball mill.

46. Guidelines for processing biota samples for metal analysis are provided by OSPAR (2018) and HELCOM (2012).

c) Storage of dried biota tissues

47. Freeze-dried tissue samples can be stored in pre-cleaned wide-mouth bottles with a screw cap. Samples intended for the analysis of metals can be stored in plastic or glass containers. For mercury analysis, samples must be stored in acid-washed borosilicate glass or quartz containers, as mercury can move through the walls of plastic containers (EC, 2010).

48. Containers with biota tissue samples should be archived and kept in storage after the completion of the analysis, in order to be used as a replicate sample in case crosschecking of the results are required or additional determinations are needed in the future. Freeze-dried biota tissues remaining after analyses could be stored in the original sample bottle, closed with an airtight lid to protect against moisture and stored in a cool, dark place. Under these conditions, samples may be archived and stored for 10-15 years. (EC, 2010).

3.2 Protocol for the treatment of biota samples prior to analysis of organic contaminants

a) Storage of wet samples on board

49. Upon collection wet samples have to be stored on board in such a way as to preserve them from deterioration that will affect the subsequent analysis of contaminants. When the fish transport to the laboratory is done in less than 24 hours, samples can be stored on ice. However, for longer periods, fish samples have to be frozen (-20 ºC) and transported frozen to the laboratory for further processing. Each sample should be labelled with the sample's identification number, the type of tissue, and the date and location of sampling.

b) Drying of biota tissues

50. For organic contaminants analysis drying procedures depends on the compounds to be analysed. For chlorinated hydrocarbons biota can be freeze-dried taking care to avoid determinant loss through evaporation by keeping the temperature in the evaporation chamber below 0°C. (OSPAR, 2018). For PAH determination, freeze-drying of biota tissues may be a source of contamination due to the back-streaming of oil vapours from the rotary vacuum pumps. Furthermore, drying may result in losses of the lower molecular weight, more volatile PAHs through evaporation. A possible way to protect samples from contamination is to cover the sample containers with a filter paper perforated with a small hole (HELCOM, 2012). Frozen biota samples are placed in clean wide-mouth glass containers suitable for freeze-drying and are freeze-dried for 24 hours taking care to protect them from cross-contamination from particles and vapors. Then the containers with the samples are weighted and freeze-dried again for another 24 hours and weighted. If the difference between the 2 weighing is less than 0.5%, drying is completed and the dw/ww ratio can be calculated. Otherwise the drying cycle can be repeated (24 hours) until the difference between successive weighing is less than 0.5%.

51. Freeze dried biota tissues are then grinded and homogenized using a plastic-free ball mill.

c) Storage of dried biota tissues

52. Freeze-dried tissue samples can be stored in pre-cleaned wide-mouth bottles with a screw cap. Samples intended for the analysis of organic contaminants should be stored in glass containers.

53. Containers with biota tissue samples should be archived and kept in storage after the completion of the analysis, in order to be used as a replicate sample in case crosschecking of the results are required or additional determinations are needed in the future. Freeze-dried biota tissues remaining after analyses could be stored in the original sample bottle, closed with an airtight lid to protect against moisture and stored in a cool, dark place. Under these conditions, samples may be archived and stored for 10-15 years. (EC, 2010).

Guidelines for monitoring chemical contaminants in the sea using marine organisms

REGIONAL SEAS

UNITED NATIONS ENVIRONMENT PROGRAMME SEPTEMBER 1992

Guidelines for monitoring chemical contaminants in the sea using marine organisms

Reference Methods For Marine Pollution Studies No. 6

Prepared in co-operation with

FAO

IOC

IAEA

UNEP 1992

NOTE: This document has been prepared in co-operation between the United Nations Environment Programme (UNEP), The Food and Agriculture Organization of the United Nations (FAO), the International Atomic Energy Agency (IAEA) and the Intergovernmental Oceanographic Commission (IOC) under project FP/S102-88-03 (2849).

For bibliographic purposes this document may be cited as:

UNEP/FAO/IOC/IAEA: Guidelines for monitoring chemical contaminants in the sea using marine organisms. Reference Methods for Marine Pollution Studies No. 6, UNEP 1992.

PREFACE

The Regional Seas Programme was initiated by UNEP in 1974. Since then the Governing Council of UNEP has repeatedly endorsed a regional approach to the control of marine pollution and the management of marine and coastal resources and has requested the development of regional action plans. The Regional Seas Programme at present includes ten regions and has over 120 coastal States participating in it (1),(2).

One of the basic components of the action plans sponsored by UNEP in the framework of the Regional Seas Programme is the assessment of the state of the marine environment and of its resources, and of the sources and trends of the pollution, and the impact of pollution on human health, marine ecosystems and amenities. In order to assist those participating in this activity and to ensure that the data obtained through this assessment can be compared on a world-wide basis and thus contribute to the Global Environment Monitoring System (GEMS) of UNEP, a set of Reference Methods and Guidelines for marine pollution studies are being developed as part of a programme of comprehensive technical support which includes the provision of expert advice, reference methods and materials, training and data quality assurance (3). The Methods are recommended to be adopted by Governments participating in the Regional Seas Programme.

The methods and guidelines are prepared in co-operation with the relevant specialized bodies of the United Nations system as well as other organizations and are tested by a number of experts competent in the field relevant to the methods described.

In the description of the methods and guidelines the style used by the International Organization for Standardization (ISO) is followed as closely as possible.

The methods and guidelines, as published in UNEP's series of Reference Methods for Marine Pollution Studies, are not considered as final. They are planned to be periodically revised taking into account the development of our understanding of the problems, of analytical instrumentation and the actual need of the users. In order to facilitate these revisions the users are invited to convey their comments and suggestions to:

Marine Environmental Studies Laboratory
IAEA Marine Environment Laboratory
19, Avenue des Castellans
MC 98000 MONACO

which is responsible for the technical co-ordination of the development, testing and intercalibration of Reference Methods.

The present document was prepared at the initiative of FAO, the Food and Agriculture Organization of the United Nations as part of its contribution to the Regional Seas Programme and in particular the Mediterranean Action Plan. The assistance of Dr. G. Topping with this work is particularly appreciated. The document was subsequently edited at IAEA's Marine Environmental Laboratory and reviewed by GEMSI, the IOC/UNEP Group of Experts on Methods, Standards and Intercalibration. The assistance of all those who participated in this work is gratefully acknowledge.

CONTENTS

1. SCOPE AND FIELD OF APPLICATION

This publication provides guidlines for monitoring chemical contaminants in the sea using measurements in marine organisms. It describes strategies for applying such measurements to the protection of public health, the assessment of the geographical distribution of contaminants and the evaluation of time trends in contamination which in turn can demonstrate the effectiveness of measures designed to control potential sources of pollution.

3. INTRODUCTION

Marine organisms can accumulate contaminants from seawater, suspended particulate matter, sediments and their food. It has also been demonstrated, through field observations and experimental studies, that the concentration of some contaminants in tissues are related to the concentrations in the surrounding environment. This process, termed bio-accumulation, has been used by scientists to assess the marine contamination which has been caused by man's activities (eg. marine disposal of wastes by pipeline discharges and dumping from ships).

There are however certain difficulties in using bio-accumulators, or bio-indicators as they are sometimes known, for this purpose. For example, individuals of the same species exposed to the same concentration of contaminants for the same period of time will not accumulate the substances at the same rate. This is related to such factors as age, sex, size and physiological state of the individual. Similarly, different species do not bio-accumulate to the same level when they are exposed to the same concentration of contaminant in sea water, and often have different rates of contaminant elimination.

Therefore, careful consideration must be given to the above factors when a monitoring programme is designed in order to reduce (or allow for) the effects of natural variability.

This document provides guidance on the design of such programmes and is intended for scientists who are responsible for marine pollution monitoring programmes. It is particularly aimed at programmes which fall under the auspices of the UNEP, IOC and FAO.

The guidelines presented in this report cover the following aspects of marine pollution monitoring programmes:

- aims
- pilot studies
- criteria for the selection of contaminants, organisms and locations to be studied
- size of sample
- frequency of sampling operations
- tissue selection.

Although an important component of these programmes is the analysis of contaminants in samples, this matter will not be addressed in detail in this document since other UNEP Reference Methods For Marine Pollution Studies cover this topic. Readers of this document are therefore advised to have the relevant analytical documents to hand (see UNEP/IOC/IAEA 1990); particularly "Contaminant monitoring programmes using marine organisms: Quality Assurance and Good Laboratory Practice" Reference Method No 57, since this deals with all aspects of work which influence the quality of data.

4. DEFINITIONS

Before discussing the programmes for which these guidelines may be used, it is necessary to define some of the more important terms which are used in this report.

Term	Definition
Accuracy, precision limit of detection	See definitions in Appendix 2 of Reference Method No 57.
Anthropogenic	Derived from human activity
Contamination	in the context of the marine environment this term describes a situation where either the concentrations of some natural substances (eg. metals) are clearly above normal values, or the concentrations of man-made substances (eg. DDT) is detectable but which do not necessarily cause deleterious effects (referred to as pollution, see definition below).
Bio-indicator	A species which accumulates a contaminant in its tissue in amounts that are proportional to the levels of the contaminant in the local environment (ie. water, sediment and food).
Hot spot	An area of the sea where there is a significantly high level of contamination
Pollution	The Group of Experts on Scientific Aspects of Marine Pollution defines pollution as "the introduction by man, directly or indirectly, of substances or energy into the marine environment (including estuaries) which results in such deleterious effects as harm to living resources, hazards to human health, hindrance to marine activities including fishing, impairment of quality for use of seawater and reduction of amenities."
Monitoring	A programme of repeated measurements of contaminants in marine samples which is carried out for a specific purpose eg. annual measurements of mercury in the edible tissue of fish to provide information on the potential annual intake of mercury by consumers. A study of mercury in fish which examines levels in different species would not be classed as monitoring. If, however, this study was repeated in subsequent years these sets of data would be classed as `monitoring data'.

Pilot study Measurements of contaminants in marine samples, in an area not previously studied, to investigate the current levels of contamination. This work is a prerequisite to a monitoring programme since the information collected in this study enables the investigator to design the sampling programme suited to the specific aims of the monitoring work. Without such information the investigator may be unable to judge which contaminants, organisms and locations to select for the monitoring programme.

Quality Assurance All procedures that are carried out by a laboratory to ensure that it produces data of the appropriate quality to meet the defined aims of its monitoring programme. Quality Assurance essentially consists of two elements - quality control and quality assessment. Definitions of these latter terms are given in UNEP Reference Method No 57.

5. AIMS OF MONITORING PROGRAMMES

There are three principal aims of monitoring programmes which involve the collection and analysis of marine organisms; they are:

- to compare contaminant levels in the edible tissues of marine organisms against national limits and to provide data to calculate the potential amount of contaminant taken in by consumers (ie Public Health monitoring).

- to compare the levels of contamination in different geographical areas (Spatial Monitoring). Such measurements are often made to assess whether the current discharges of wastes are producing unacceptable levels of contamination ie they are causing, or likely to cause, marine pollution problems.

- to measure the levels of contaminants over time at particular locations to judge whether they are changing in relation to the inputs of contaminants (ie Trend Monitoring). Such measurements are made to assess the efficiency of measures taken to reduce pollution.

Investigators should write down the specific aims of each monitoring programme before commencing any field measurements. These aims are needed to narrow the list of parameters, species and sites to be investigated). There are two distinct aspects of aims:

Environmental management - Are standards complied with? What is the spatial extent of contamination? What are the changes of levels with time in relation to changes in inputs of contaminants?

Environmental science - Statistical significance of differences in levels of contaminants - representative sampling of the population - selection of analytical methods with the required accuracy and precision.

6. PILOT STUDY

This assists the investigator in the design of an efficient monitoring programme for each specific aim. Provided a pilot study is carefully planned (see Appendix 1 for guidance), it can provide the following information:

a) In relation to public health studies, it can identify the relevant edible species, particularly the ones which contain elevated levels of regulated contaminants and therefore merit further investigation to determine the need for additional regulatory action, such as input controls or restriction on the harvesting or consumption of fish/shellfish.

b) It can identify which areas of the marine environment are sufficiently contaminated to warrant monitoring.

c) It can provide an indication of the variability of contaminant levels in individuals of the same species from the same population and location. This information is essential to an investigator wishing to establish a programme of trend monitoring. Without it, he may not be able to judge whether his sampling and analytical work will be sufficiently detailed to detect changes in contaminant levels with time against the natural fluctuations that may exist in any population of organisms.

d) It can identify which tissues of organisms, particularly fish and large shellfish, are the most appropriate ones to use in specific monitoring programmes since not all tissues reflect changes in the levels of contaminants in the environment to which the organism is exposed.

e) It can identify, and sometimes quantify, inputs of contaminants to the study area. This will help the investigator to select which contaminants should be given priority, if the resources for monitoring are limited, and in which areas contaminated organisms are likely to be found.

A pilot study can easily be expanded in order to accommodate measurements of biological effects. These effects may include changes in community structure and populations or adverse changes in the biochemistry of organisms (for example, acetyl cholinesterase depression by organophosphorus pesticides). Linkage of "levels" with "effects" is an important step in a complete pollution assessment. When effects are noted on a pilot scale, associated with specific contaminants or groups of contaminants, a strong case can be made for incorporating such contaminants in a full-scale monitoring programme and for taking immediate measures for their control and abatement. Details of some biological effects measurements are included in the Reference Method Series (see UNEP/IOC/IAEA, 1990).

Once a pilot study has been successfully completed, and the results evaluated, the investigator should prepare a protocol for each specific monitoring programme for the collection and analysis of samples. This protocol will specify what information is required to meet the specific aims, and the criteria to obtain the required quantity and quality of data. Time spent on the planning of a statistically significant sampling and analytical programme, will inevitably produce a more efficient programme which makes the best use of the laboratory's most important resource (ie staff time). Initially, it is generally sensible to conduct a programme which satisfies essential, rather than very ambitious, aims. It is relatively easy to expand this basic programme if extra resources become available. Finally, it is necessary to review the monitoring programme on a regular basis, to assess how well the aims are being met. This review may result in a reduction of effort on sampling and analyses, and the time gained can be usefully employed on other aspects of marine pollution studies. However, it might identify the need to put in more effort.

7. DESIGNING A MONITORING PROGRAMME

There are a number of factors to be considered in the planning of a monitoring programme which is to meet specific aims:

a) Which contaminants should be measured?

b) Which organism(s) should be selected?

c) Where should the samples be collected?

d) When should the sampling be done and how frequently should it be carried out?

e) How many individual organisms should be collected on each sampling occasion and which size(s) should be included in each sample?

f) Which tissue(s) of the organism(s) should be selected for analysis?

It is the principal investigator, together with a knowledgeable statistician and biologist, who will have to do this evaluation, design and plan the sampling work, prepare the necessary instruction sheets for the field staff, discuss with the analysts the precautions to be taken by staff in the storage and processing of samples prior to their analysis.

Specifically, the investigator will have to do the following:

(i) Design a sampling programme for the organisms of interest; selecting sufficient numbers, and sizes, of individuals at each site at appropriate intervals of time to take into account the inherent variability of contaminant levels in the organisms. This work will be done on the basis of the results obtained from the pilot study and any relevant information from other similar studies. Sampling must be designed to provide a statistically sound basis on which to judge changes in contaminant levels. Once this sampling programme has been designed, instruction sheets should be prepared and issued to the field staff.

(ii) Ensure that samples are collected, stored and transported to the laboratory in a way which minimizes losses and gains of contaminants prior to analysis. Guidance on this can be obtained by consulting the relevant documents in the UNEP Reference Methods series. Again it will be necessary to prepare instruction sheets for field and laboratory staff.

(iii) Arrange for the processed samples to be analyzed using methods which have the required accuracy and precision. Experience has shown that close collaboration between the principal investigator and the analysts is essential if this work is to be successful. The investigator and the principal analyst should consult the UNEP Reference Method No 57 which gives guidelines on Quality Assurance, if they are in any doubt about how to achieve and maintain the required quality of analytical data.

(iv) Ensure that there is an adequate system of documentation to allow samples to be traced from the time of collection to the recording of analytical data. The investigator should ensure that all relevant staff are aware of, and comply with, the system of documentation (see Appendix 2 for more details on this matter).

Each of the factors a - f will now be considered in more detail.

8. SELECTION OF CONTAMINANTS

The selection of substances to be monitored will be determined by a) the aims of the monitoring programme, b) the findings of the pilot study (ie which contaminants, present at significant levels above the background values, justify further study), and c) the ability of the analyst to measure these substances with the required accuracy and precision. In practice the last factor will often determine whether a particular contaminant or group of contaminants can be included in the monitoring programme.

It is essential that the principal investigator and the principal analyst agree to the required accuracy, precision and limit of detection for the measurements to ensure that the necessary standards of analysis are achieved eg. it would be inappropriate to consider measurements of specific changes in contaminant levels using an analytical method which had an inadequate level of precision.

If the analytical method used in the pilot study does not meet the required standard for the specific monitoring purposes, the analyst must select another method which meets the required standard. If for any reason this is not possible (eg. there is a statutory requirement to use a particular method) the investigator should abandon the proposed monitoring programme. Any other action will merely result in wasted effort, since the aims will not be met using an inadequate analytical method. However, it must be stressed that the use of an analytical method which, in theory, has the required performance characteristics to meet the aims does not necessarily guarantee success. Other factors have to be taken into account in obtaining the required quality of analytical data. These are discussed in some detail in "Quality Assurance and Good Laboratory Practice in relation to Marine Pollution Monitoring Programmes", UNEP Reference Method No 57. Investigators are strongly advised to obtain a copy of this document for analysts at the outset of the work.

In addition to selecting contaminants to meet the aims of the laboratory's marine pollution programme, it may be appropriate to include other contaminants which meet regional and international needs. This should only be considered if the additional data is useful to the laboratory, or if it is part of the laboratory's commitment to Regional Studies, and does not jeopardize the main aims of the laboratory's monitoring programme. A list of contaminants, identified by some organizations (International Council for the Exploration of the Seas, Oslo and Paris Commission's Joint Monitoring Group) for monitoring work in the North Sea and adjacent waters as well as those recommended (category I and II substances) for the MED POL programme are given, for information, in Appendix 3.

The final selection of contaminants should also be related to knowledge of their likely sources (eg. an extensive monitoring programme for pesticides along a desert coastline would be unwarranted) and information from scientific literature on their transport and persistence in the environment. Such information will also help to identify which environmental compartment should most usefully be monitored. As an example, organophosphorus pesticides are rapidly metabolized by many marine organisms but are rather persistent in sediments. It would be pointless to monitor them in biota but highly relevant to monitor their biological effects.

9. SELECTION OF ORGANISMS

9.1 Spatial and trend monitoring

Experience has shown that the most reliable data on contaminant trends in organisms are obtained by sampling organisms which have the following characteristics:

- A simple relationship exists between contaminant residues in the organisms and the average concentrations in the surrounding seawater or sediments.
- The organism accumulates the contaminant without being affected by the levels encountered.
- The organism is sedentary and thus representative of the area of collection.
- The organism is widespread in the study region, to allow comparisons between different areas.
- The organism is sufficiently long-lived, to allow sampling of more than one year class if desired.
- The organism is of a reasonable size, to give adequate tissue for analysis.
- The organism is easy to sample and robust enough to survive in the laboratory, allowing (if desired) depuration before analysis and, if needed, studies of uptake of contaminants.
- The organism exhibits high concentration factors, to allow direct analysis without pre-concentration.
- The organism is tolerant of brackish water, to allow comparisons to be made between estuarine and offshore sites.

These characteristics restrict the useful organisms to a range of fairly large, abundant, widespread, inter-tidal organisms, mainly molluscs. Filter-feeding molluscs are more likely to reflect contaminants in the water column, whilst deposit feeders will also be influenced by sediment chemistry. The working of the sediments both by organisms and water currents will cause an averaging of short-term variations in contaminant loading. Water chemistry, however, will more rapidly respond to effluent discharges and dispersal conditions at the time of sampling. Filter-feeders are therefore more likely to provide the information required to fulfill the objectives of a monitoring programme concerned with water quality. In Appendix 4, lists are given of organisms which some scientists in the United Kingdom have suggested may be used for monitoring a range of metals and organochlorine compounds in either rocky or muddy inter-tidal areas in UK waters.

In practice the selection of an organism, for monitoring purposes, is determined by its availability in the study area and its known ability to act as a bio-indicator. If this latter information is not known it must be obtained from either the scientific literature (eg. Phillips 1980), or the pilot study. Final selection should be made in consultation with a knowledgeable biologist. Common mussels, (Mytilus edulis, M. californianus and M. galloprovincialis), that are used in global mussel watch programmes are generally suitable for spatial and trend monitoring programmes in coastal waters.

Other species of shellfish, and fish, can be used for spatial and trend monitoring purposes provided the organism can be shown to accumulate the specific contaminant(s) and that the concentrations of the contaminant(s) are in proportion to the concentrations in either water or sediment or food.

9.2 Public Health programmes

If the pilot study has revealed that edible species from the local fishery contain levels of contaminants which approach or exceed statutory limits for contaminants in foodstuffs, then these organisms should be included in any subsequent public health monitoring programme.

Since permissible limits of some contaminants (eg. Cd) in foodstuffs are extremely low, the analytical method for this work must be capable of producing the required data quality. A high degree of accuracy, and a detection limit which is ca 1/10 of the permissible concentration of the contaminant in the foodstuff, are essential for this work. These criteria enable the analyst to have confidence in the results that are provided to managers for regulatory purposes.

10. LOCATION OF SAMPLING SITES

10.1 Spatial and trend monitoring

Hot spots are usually found in estuarine and coastal areas where anthropogenic wastes are discharged. The offshore areas where hot spots are most likely to occur are those used for the dumping of wastes from ships or those in the vicinity of offshore oil platforms.

A decision to monitor contaminant levels in `hot spots' should be taken only after careful consideration of the discharges to these areas. If, as a result of the pilot study, the relevant authorities decide to reduce inputs then it would be appropriate to monitor to judge whether the new controls have been effective in reducing levels in organisms. If no action is to be taken on the regulation of discharges then monitoring is only justified if there is a good reason to update the information collected in the pilot study.

Other estuarine, coastal and offshore sampling sites may be included in the programme to provide coverage of both clean and moderately contaminated areas. All sampling should be done by scientific personnel operating from research or chartered vessels, rather than by fishermen, to ensure that contamination of the samples during and after collection is kept within acceptable limits.

For long-term monitoring programmes, the precise locality of sampling sites should be registered as very small spatial variation may strongly influence the final data (ie "mussels from the harbour wall" should specify which point in the harbour wall). In some cases it may be useful to photograph the sites, particularly where intertidal organisms are taken.

10.2 Public Health Programmes

In some countries there may be officials who are knowledgeable about the edible species of fish and shellfish caught by commercial fishermen. Investigators may find it helpful to discuss their proposed monitoring programme with such officials since they can often offer valuable advice in the design of the collection programmes.

Samples of fish and shellfish may be obtained from the fish markets or from fishing vessels or research ships which are operating in traditional fishing areas. The basic requirement is a representative sample of the species normally consumed by the general public. It should be noted, however, that some countries may specify the exact sampling procedures for public health monitoring.

Commercial fishermen do not usually take any special precautions during the collection, storage, transport and off-loading of their catches, other than to ensure that they are presentable enough for sale. The retailer and the consumer do not normally adopt any stringent dissection procedures, other than from a public health viewpoint. The scientist, however, will use careful sampling and pre-treatment procedures to ensure that contamination is kept within acceptable limits. These different approaches to sampling may lead to differences in the amount of contaminants found in the samples. In general the scientific samples will be less contaminated than those taken from fish markets, fishing boats and fish retailers.

The final decision on where and how to collect samples for public health monitoring will depend on whether information is required on actual contaminant intake by the consumer (in which case samples will be taken from the fish markets or fish retailers) or whether the aim is to determine which edible species and areas are exposed to contamination (in which case the sampling must be done by scientific staff).

11. PERIOD AND FREQUENCY OF SAMPLING

11.1 Spatial and trend monitoring

For spatial monitoring, collections should be made over a short interval of time (within weeks rather than months) to enable a synoptic comparison of concentrations of contaminants at different sites. This also helps to ensure that organisms are in the same physiological state. If major annual changes in the quantity and/or composition of inputs are anticipated it would be appropriate to conduct an annual or biennial sampling. Experience has shown that the effects of changes in inputs of contaminants are often confined to the area in the immediate vicinity of the discharge. It is these areas where more frequent monitoring should be conducted.

For trend monitoring, the frequency of sampling will a) reflect the time scales over which the changes are required to be detected, b) the degree of confidence required in the measurement of these changes, and c) the available laboratory resources. Investigators should note that there is nothing more frustrating and time-wasting than a programme in which the proposed work is well below the minimum standard required to detect the desired changes in contaminant levels. If, for any reason, the resources are insufficient to meet the specific aims of the programme, then the programme should be canceled and replaced with one which has less ambitious aims but which can be carried out successfully with available resources.

If no changes in inputs are expected, then it would be sensible to restrict sampling to ca 5 yearly intervals. A more frequent sampling programme can only be justified if there is a need to provide more regular data for other purposes eg. to reassure the general public that levels of contaminants are not changing.

Seasonal variations in food supply, and the spawning cycle, are known to cause changes in total body weight, as well as lipid concentration and composition and, these may influence contaminant levels in the tissues of some organisms. In order to minimize these variations, it is suggested that sampling be undertaken at the pre-spawning period.

11.2 Public Health monitoring

Unless there is a seasonal fishing pattern for some species, samples may be taken at any time of the year. Ideally all species should be sampled at the same time so that a synoptic picture of the contaminant levels can be obtained. A typical monitoring programme might consist of a survey every 5 years. A more frequent sampling programme (ie annual) will be needed if the results of the pilot programme show that concentrations of contaminants in foodstuffs approach or exceed permissible limits for foodstuffs. Increased sampling should be confined to the particular species and contaminants which give cause for concern.

12. SIZE OF SAMPLE

12.1 Spatial and trend monitoring

Ideally, the investigator will have established the relationship between contaminant levels and size of organisms from the results of the pilot study. It is good practice to select a particular size or size range to minimize the variance of contaminant levels from sample to sample. The number of individuals required for each sample will be determined by the magnitude of the change that is considered to be significant in relation to the specific aims. The smaller the difference the greater the number of individuals required for each sample. (See Appendix 5 for further guidance)

If the relationship between size of organism and contaminant level has not been obtained from the pilot study then a sufficient number of individuals should be collected at one of the sampling sites to cover the size range of organisms in the population, to establish the variability of contaminant levels with size. This is a minimum requirement since, ideally, this sampling procedure should be done at all sites. The information on variability at one site will allow the investigator to make comparisons with other sites where individuals of a limited size range are collected.

If either analytical resources or sample material is limited it may not be practical for the individuals from each site to be analyzed separately. In this case, individuals should be combined to make one sample (often referred to as `pooled' samples). For `pooled samples', no information will be obtained on the variation of contaminant levels with size but the data can be used to assess site to site differences with some level of confidence, provided that a number of replicate analyses are done on each of the `pooled' samples, and the `pooled' samples consist of individuals from the same size range.

12.2 Public Health monitoring

The size(s) of organisms to be sampled should be based on information on consumption patterns. If a range of sizes is sold, then these different sizes should be analyzed. The number of individual organisms in each sample will be influenced by the importance of the species as a foodstuff, the availability of scientific manpower and the need to sample sufficient numbers of each species and of each size category to cover the range of values encountered in a typical population or catch. Generally, a sample of 5-10 individuals from each size range of fish and large shellfish (crabs, lobsters) and ca 50 individuals for smaller shellfish (eg. mussels, shrimps) would be sufficient.

13. SELECTION OF TISSUE

13.1 Spatial and trend monitoring

For invertebrates, whole soft tissue (less viscera) should be taken for analysis.

For fish, muscle is the most useful tissue for most purposes. However, liver and kidney tissues have been used for studies of fish and the digestive gland of large crustaceans. In general, whole soft tissue is taken for smaller shellfish.

13.2 Public Health monitoring

Only edible tissue need be analyzed for contaminants - usually this means muscle tissue for fish and large crustaceans and whole soft tissue (less viscera, ie guts, gills and gonad) for small shellfish.

Every opportunity should be taken to collect data on the size (or length) and age of the species. This may be relevant to subsequent decisions on regulatory action.

13.3 Normalization procedures

It is usual to report all tissue data on a dry weight basis (ie. g contaminant/g (dry weight)). However, some literature values use wet weight which may be required for public health studies. Since drying is a common part of most analytical protocols (see RM. No. 7 "Sampling of selected marine organisms and sample preparation for trace metal analysis" and RM. No. 12 "Sampling of selected marine organisms and sample preparation for the analysis of chlorinated hydrocarbons"), the reader is advised to record wet/dry weight ratios on a routine basis.

In the case of lipophilic contaminants, such as chlorinated hydrocarbons, contaminant concentrations are often expressed in terms of g contaminant/g HEOM (where HEOM is Hexane Extractable Organic Matter, principally lipid). This procedure enables a certain degree of normalization for seasonal or spatial variations in the lipid content of sentinel organisms and facilitates the comparability of data.

Appendix 1

GUIDANCE ON THE PLANNING OF A PILOT STUDY

Desk Study

It is important to determine what is known about contaminants in the proposed study area, before any field work is done. Some of this information can be found by reviewing the relevant scientific journals and other published material (eg. books, conference proceedings).

Annual reports of other marine institutes, local and central government and industrial research laboratories are also useful sources of data, as are unpublished scientific reports from these organizations. If these latter sources provide useful data, it is good practice to contact scientists from the relevant organizations to identify whether there is any other unpublished data or information, which might be useful to the investigator.

This review can often provide data on the current levels of contamination in water, sediments or biota and occasionally information on inputs of contaminants to the area via rivers, pipelines or dumping from ships. It may also reveal the type of industry and agriculture located in the coastal region, the range and scale of potentially toxic substances used by them, and possibly information on their discharges to the rivers and sea. These latter data should be verified by contacting the local or national authority, which has responsibility for regulating discharges to rivers and coastal waters. This authority should also be approached for information on the past and present discharges to the area.

For public health work, the investigator should identify which fish and shellfish species are caught for human consumption, and whether there are relevant permissible limits for contaminants in marine foodstuffs. Information on commercial catches can be obtained from either the local fishermen or their representative organizations or the local or central government fisheries department. Information on food standards can be obtained from the local environmental health department or the central government department responsible for food safety. It is difficult to be more specific about the exact sources of the above information in each country since they do vary from country to country.

This review should enable the principal investigator to identify the group of contaminants, and specific fish and shellfish, which should be given priority in the pilot study for public health purposes. It will also give some general guidance on the species to be selected for spatial and trend monitoring purposes. However, before the principal investigator can plan this latter work he needs to do some additional desk work to identify the locations where samples should be collected.

Identifying sampling sites

It is essential that the pilot study covers the areas which are likely to be contaminated and the areas which, from a hydrographic and input viewpoint, are unlikely to be significantly affected (ie sites located well offshore from industrialized areas or those located in inshore areas next to less populated and industrialized areas).

The level and extent of contamination in coastal and estuarine waters is determined by:

- the rate of input of contaminants
- the location of the individual inputs
- the composition of the waste - whether the contaminants are in solution, attached to solids or associated with mixtures of solid and liquid
- the dilution and dispersion of wastes following discharge, and in the case of discharges containing solids, the settlement of solid material to the sea bed sediments
- the physical and chemical processes in the sea (ie adsorption and desorption of substances between dissolved and particulate phases of seawater).

Unless the principal investigator has a good working knowledge of hydrography of the local area, it will be necessary to seek the help of an hydrographic expert to determine the optimum locations for sampling in relation to known inputs.

Assuming the principal investigator can provide the hydrographer with the relevant information on inputs, and that his colleague has a good understanding of the hydrographic characteristics of the area (direction, speed and variability of currents, salinity and temperature of the water masses, and the freshwater flows to the sea) it should be possible to calculate the theoretical dilution and dispersion of wastes at estuarine and coastal sites. This information can then be used to identify the locations where organisms are exposed to contamination and the adjacent areas where they will probably not be subject to contamination (ie clean or control areas).

If expert hydrographic advice is not available, the principal investigator should establish a sampling grid along the likely gradient of contamination; with sampling sites located at progressively increasing distances from the input (100m, 300m, 1000m, 3000m etc.). If a river is the principal source of contamination to the study area, the investigator can establish his sampling grid along the salinity gradient. It is relatively easy to calculate the dilution of river water, and the corresponding dilution of contaminants, by measuring the salinity at locations in an estuary and comparing these measurements with the salinity values of the water entering the estuary. For this calculation, the investigator assumes that river water has zero salinity and that the contaminants behave conservatively during mixing of freshwater and seawater.

Sample size

The concentration of some contaminants can vary with size of the organisms. It is important in spatial and trend monitoring to reduce this source of variability in the data to detect differences in contaminant levels between sites and with time (see Appendix 5). If this relationship is not known by the investigator prior to the commencement of monitoring, it will be necessary to establish it during the pilot study.

To do this, the investigator must collect a representative sample of each population of species at each sampling site. This sample should include sufficient numbers of individuals to cover the range of sizes/ages/lengths of individuals in each population. The investigator should consult a knowledgeable biologist for guidance on the range of sizes that might be expected for each species.

Selection of tissue

Although there is considerable scientific literature on the accumulation of contaminants by different tissues (eg. Phillips, 1980), it is advisable for the investigator to check this aspect for the specific organisms to be examined in the pilot study. It is also advisable to consult a biologist to determine the best procedure for dissection of organisms into their constituent parts, to ensure that there is no possibility of one tissue being contaminated by another.

Ideally, the investigator should investigate the relationship between the contaminant level, tissue and size of organism by analyzing tissue from individuals of different sizes rather than by analyzing pooled samples; even if the latter consist of a number of individuals of the same size or size range. However, if analytical resources are limited, it may be necessary for him to establish this relationship by analyzing pooled samples.

Appendix 2

DOCUMENTATION OF DATA

The adoption of the following guidelines by a laboratory should provide adequate documentation to allow it to trace samples from the collection stage to the completion of its analyses by providing a record of the appropriate data in logbooks or in computer files.

Documentation

(i) Descriptions of the sampling strategy, methods of sample collection, procedures for storage, and pre-treatment and analytical procedures, plus a list of ancillary site observations;

(ii) Sample documentation (description of organisms, numbers of individuals collected for each sample, weights of tissue taken for analysis (individual tissue or homogenate) plus ancillary data on organisms (length, weight and age);

(iii) Description of analytical procedures, including details of accuracy, precision and limit of detection;

(iv) Description of quality control and quality assessment and evidence that these procedures have been applied and have provided acceptable data;

(v) Description of working standards used on each occasion and calculations of results;

(vi) A secure system for the long term storage of data either in logbooks or computer files is essential. It is also advisable to have a duplicate set of records in case one is lost, mislaid or accidentally destroyed;

Advice should be sought on the correct method of storing computer tapes and/or discs to ensure the long-term stability of data files.

Storage of data

It has been shown that even the most experienced personnel can make simple arithmetic errors in calculating results. Thus, a check should be made for such errors before compiling tables of results. Once this check has been MADE it is appropriate to carry out a preliminary assessment of the quality of the data, prior to its evaluation and publication, to ensure that no erroneous results are included. This assessment can include a comparison of the results with existing data (ie data for the study area either previously collected by the laboratory or data published in the literature). Before consigning data to long term storage, a final check should be made to ensure that no errors have been made in transcribing the data (ie the re-typing of data sets by typists or data processors can sometimes lead to such errors).

Appendix 3

EXAMPLES OF CHEMICAL SUBSTANCES MEASURED IN MARINE ORGANISMS FOR MONITORING PURPOSES (SOURCE:

Trace metals

Arsenic (As), Cadmium (Cd), Chromium (Cr), Copper (Cu), Lead (Pb), Mercury (Hg), Nickel (Ni), Tin (Sn), and Zinc (Zn).

DDT and its metabolites

o,p'-DDD, p,p'-DDD, o,p'-DDE, o,p'-DDT, and p,p'-DDT.

Chlorinated pesticides other than DDT

Aldrin, Alpha-Chlordane, Trans-Nonachlor, Dieldrin, Heptachlor, Heptachlor epoxide, Hexachlorobenzene, Lindane (gamma-BHC), and Mirex (+ Endosulfan ?)

Polychlorinated biphenyls (PCBs)

Measurements are usually restricted to either a small number of individual compounds (known as congeners) or to the total concentration of PCBs.

Polyaromatic hydrocarbons

These can include:

2-ring compounds	Naphthalene, 1-Methylnaphthalene, 2-Methylnaphthalene, 2,6-Dimethylnaphthalene, and Acenaphthene.
3-ring compounds	Fluorene, Phenanthrene, 1-Methylphenanthrene and Anthracene.
4-ring compounds	Fluoranthrene, Pyrene, and Benz(a)anthracene
5-ring compounds	Chrysene, Benzo(a)pyrene, Benzo(e)pyrene, and Dibenz(a,h)anthracene.

For the purposes of the Long-term programme for pollution monitoring and research in the Mediterranean sea (MED POL - Phase II) the following chemical contaminants were identified for analysis in marine organisms.

category I (mandatory)	category II (optional)
total mercury	total arsenic
organic mercury	radionuclides
cadmium	polynuclear aromatic hydrocarbons
halogenated hydrocarbons	

Appendix 4

A. LIST OF MED-POL SPECIES

For the purposes of the Long-term programme for pollution monitoring and research in the Mediterranean sea (MED POL - Phase II) the following species (nearly all edible), representing different ecotypes, are recommended for the monitoring of chemical contaminants in marine organisms.

a) Bivalves

Mytilus galloprovincialis, or
Mytilus edulis, or

b) Demersal fish
Perna perna, or
Donax trunculus

M. edulis, P. perna or D. trunculus can only be monitored as alternative species if Mytilus galloprovincialis does not occur in the area.

Mullus barbatus, or
Mullus surmuletus, or
Upeneus molluccensis

M. surmuletus or U. molluccensis can only be monitored as alternative species if Mullus barbatus does not occur in the area.

c) Pelagic carnivore fish

Thunnus thynnus, or
Thunnus alalunga, or
Xiphias gladius

d) Pelagic plankton feeding fish

Sardina pilchardus
Other clupeids should only be monitored as alternative species if S. pilchardus does not occur in the area.

e) Crustaceans

Parapenaeus longirostris, or
Nephrops norvegicus, or
Penaeus kerathurus

N. norvegicus or P. kerathurus can only be monitored as alternative species if P. longirostris does not occur in the area.

B. LIST OF POSSIBLE ORGANISMS FOR THE ASSESSMENT OF CONTAMINATION IN THE NORTH ATLANTIC REGION

	Cd	Hg	Cu	Cr	Pb	Zn	HH	PHC
Rocky substrate								
Mytilus edulis (common mussel)	+		?	+	+	+	+	+
Littorina littorea (gastropod)	+		+	?	+	+		
Patella vulgata (limpet, gastropod)	+		+		+	+		
Muddy substrate								
Scrobicularia plana (da Costa) (peppery furrow bivalve)	+	+	?	+	+	+		
Macoma balthica (bivalve)	+	+	?	+	+	+		
Nereis diversicolor (annelid)	+	+	+	+	+	+		

Key: + = appears to act as good indicator
? = doubt about use as indicator
HH = halogenated hydrocarbons
PHC = petroleum hydrocarbons

NOTES: The organisms listed for muddy substrates are all deposit feeders, whilst those for rocky substrates are filter feeders or herbivores. It is unlikely that contaminant levels in the tissues of the two groups will reflect contaminat levels in the same part of the marine environment.

Annex II:

Sampling of selected marine organisms and sample preparation for trace metal analysis

REGIONAL SEAS

UNITED NATIONS ENVIRONMENT PROGRAMME

12 November 1984

Sampling of selected marine organisms and sample preparation for trace metal analysis

Reference Methods for Marine Pollution Studies No. 7 Rev. 2

Prepared in co-operation with

FAO IAEA IOC

UNEP 1984

Note: This document has been prepared in co-operation between the Food and Agriculture Organization of the United Nations (FAO), the International Atomic Energy Agency (IAEA), the Intergovernmental Oceanographic Commission (IOC) of UNESCO and the United Nations Environment Programme (UNEP) under projects FP/ME/0503-75-07, ME/5102-81-01, FP/5102-77-03 and FP/5101-84-01.

For bibliographic purposes this document may be cited as:

UNEP/FAO/IAEA/IOC: Sampling of selected marine organisms and sample preparation for trace metal analysis. Reference Methods for Marine Pollution Studies No. 7 Rev. 2, UNEP 1984.

PREFACE

The Regional Seas Programme was initiated by UNEP in 1974. Since then the Governing Council of UNEP has repeatedly endorsed a regional approach to the control of marine pollution and the management of marine and coastal resources and has requested the development of regional action plans. The Regional Seas Programme at present includes ten regions and has over 120 coastal States participating in it. 1/ 2/

One of the basic components of the action plans sponsored by UNEP in the framework of Regional Seas Programme is the assessment of the state of marine environment and of its resources, of the sources and trends of the pollution, and the impact of pollution on human health, marine ecosystems and amenities. In order to assist those participating in this activity and to ensure that the data obtained through this assessment can be compared on a world-wide basis and thus contribute to the Global Environment Monitoring System (GEMS) of UNEP, a set of reference methods and guidelines for marine pollution studies are being developed and are recommended to be adopted by Governments participating in the Regional Seas Programme.

The methods and guidelines are prepared in co-operation with the relevant specialized bodies of the United Nations system as well as other organizations and are tested by a number of experts competent in the field relevant to the methods described.

In the description of the methods and guidelines the style used by the International Organization for Standardization (ISO) is followed as closely as possible.

The methods and guidelines, as published in UNEP's series of Reference Methods for Marine Pollution Studies, are not considered as final. They are planned to be periodically revised taking into account the development of our understanding of the problems, of analytical instrumentation and the actual need of the users. In order to facilitate these revisions the users are invited to convey their comments and suggestions to:

International Laboratory of Marine
Radioactivity
International Atomic Energy Agency
c/o Musée Océanographique
MC98000 MONACO

which is responsible for the technical co-ordination of the development, testing and intercalibration of reference methods.

2/ P. HULM: A Strategy for the Seas. The Regional Seas Programme: Past and Future UNEP, 1983.

This issue (Rev.2) of the Reference Method for Marine Pollution Studies No. 7 was prepared in co-operation with the Food and Agriculture Organization of the United Nations (FAO), the International Atomic Energy Agency (IAEA) and the Intergovernmental Oceanographic Commission (IOC) of UNESCO. It includes comments received from IOC's GIPME Group of Experts on Methods, Standards and Intercalibration (GEMSI), from the FAO/UNEP/IAEA Experts Consultation Meeting on Reference Methods for the Determination of Chemical Contaminants in Marine Organisms (Rome, 4-8 June 1984) and from a number of scientists who reviewed and tested the method. The assistance of all those who contributed to the preparation of Revision 2 of this reference method is gratefully acknowledged.

CONTENTS

1. SCOPE AND FIELD OF APPLICATION

This publication describes the sampling and sample preparation procedures suitable to obtain uncontaminated samples of mussels (total soft tissue), shrimps (muscles), and fish (muscles) for trace metal analysis by atomic absorption spectrophotometry.

2. REFERENCES

BERNHARD, M. (1976) Manual of methods in aquatic environment research. Part 3 Sampling and analyses of biological material. FAO Fish.Tech.Pap. No. 158 (FIR1/T158), pp. 124. FAU, Rome.

UNEP/FAO/IAEA (in preparation). Guidelines for monitoring chemical contaminants in marine organisms. Reference methods for marine pollution studies No. 6. UNEP, Geneva.

3. PRINCIPLES

Specimens of organisms selected and collected according to UNEP/FAO/IAEA (in preparation) are enclosed in plastic containers and transported to the analytical laboratory either as cooled (-2 to 4°C) or as deep-frozen (-18°C) samples There the specimens are dissected under "clean conditions" and subsamples are prepared for the analyses of trace metals.

4. REAGENTS

4.1 Demineralized distilled water or glass distilled water of equivalent quality, with a trace metal content below detection limits when checked with this reference method.

4.2 Uncontaminated "open-ocean" subsurface (1 m below the surface) sea water.

4.3 Detergent recommended for laboratory use.

5. APPARATUS

5.1 Plastic thermo-insulated boxes (camping equipment) cooled with commercially available cooling bags. For storage and transport of mussels the boxes must be equipped with a grid in the bottom in order to avoid the mussels being submerged when moistened during transport and storage.

5.2 Refrigerator (required for 6.2, 6.3, 6.4).

5.3 Deep-freezer (-18°C).

5.4 Heavy duty, high-density polythylene bags or suitable plastic containers for storage of specimens.

5.5 Plastic length-measuring board, length-measuring scale (ruler) or transparent Pyrex dish (cooking utensil) with centimetre scale attached underneath (for small and medium-size specimens).

5.6 Two or more plastic knives made out of high-density and purity polyethylene or similar material. Alternatively, quartz knives can be used.

5.7 Pyrex dishes or porcelain dishes (cooking utensils) as working surface for sample preparation.

5.8 Two or more pairs of plastic, commercially available or "home-made", tweezers (see Appendix A).

5.9 High density and purity polyethylene bags and airtight plastic containers with screw caps, for preservation of samples in deep-freezer, cleaned with detergent (4.3) and rinsed with distilled water (4.1) or uncontaminated sea water (4.2).

5.10 High-density polyethylene sheets for covering working bench.

5.11 Smaller polyethylene sheets to be used as "weighing plastic".

5.12 Balance (100-200 g) with a precision of 0.001 g or better, for weighing specimens and subsamples; preferably a "top-loading" balance.

5.13 Plastic wash bottle containing glass-distilled water (4.1).

5.14 Scraper (figure 1), a strong rust-free knife or similar for collecting mussels.

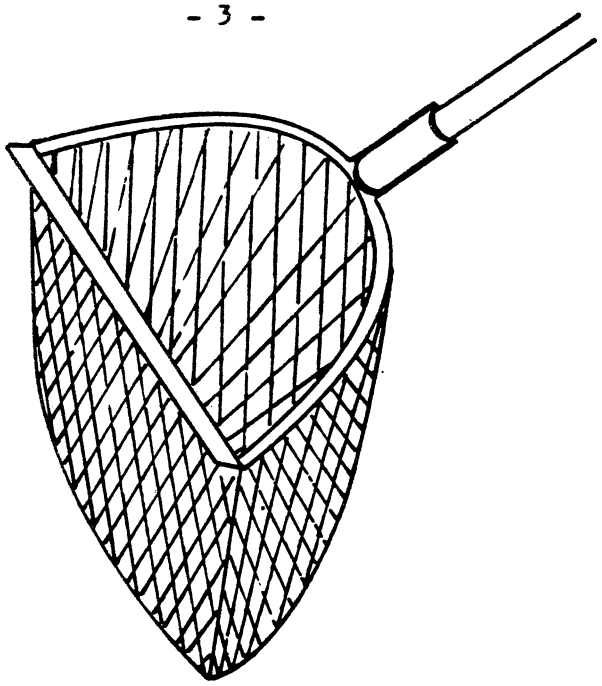

FIGURE 1 : SCRAPER FOR COLLECTING MUSSELS

5.15 Plastic tank or bottle (20 - 50 l) for the sea water (4.2) needed to moisten live mussel samples during storage and transport.

5.16 Large rust-free metal knife for cutting portions from large fishes.

5.17 Stainless steel blender or other tissue homogenizer made from glass and/or teflon. Stainless steel equipment should be tested for trace metal contamination by homogenizing reference (standard) material and comparing the analytical result obtained with same material which was not homogenized with stainless steel equipment.

5.18 Strong plastic brush for removing foreign material attached to the surface of mussels.

6. SAMPLING AND TRANSPORT

6.1 Presampling preparations

Clean the thermo-insulated boxes (5.1), the high density polyethylene bags or containers (5.4), the length-measuring board (5.5), the large rust-free knife (5.16), the scraper or the knife (5.14) with detergent (4.3) and rinse them with distilled water or, alternatively, with clean open-ocean sea water (4.2).

6.2 Sampling of mussels

Remove mussels from their attachments with the clean scraper or the rust-free knife (5.14).

Transfer a suitable number (UNEP/FAO/IAEA (in preparation)) of undamaged mussels into clean thermo-insulated boxes with grid on the bottom (5.1). Collect, from the sampling site, a clean sea water sample in a suitable container (5.15) to keep the mussels moist if a long transport (more than 2 hours in hot climates) is envisaged. Keep the mussels moist with the clean sea water without submerging them.

If the mussels have to be transported and stored before sample preparation (7) for more than 24 hours place a suitable number of mussels in plastic bag (5.9). Squeeze out the air and close the bag airtight with a knot, thermoseal, or similar. Place the bag into another bag (5.4) together with a sample identification note (see Appendix B), close airtight the second bag and deep-freeze.

This represents the "specimen sample".

NOTE: The transport of mussels collected near the laboratory will not present special transport and storage problems. Mussels should be kept exposed to air and moistured with clean sea water during the transport to the laboratory. When gathered from the intertidal zone, they will survive aerial exposure for 24 hours. Mussels submerged in sea water during transport will open their valves, start pumping water and excreting waste products, while during aerial exposure their valves will remain closed and their metabolic rate is greatly reduced; therefore their submersion in sea water during transport should be avoided.

6.3 Sampling of shrimps and small to medium-size fish

Place in a clean plastic bag (5.4) a suitable number of the undamaged specimens (select according to UNEP/FAO/IAEA (in preparation)) collected from a fishing vessel, fish market, etc., taking care that the legs, spines, etc. will not puncture the plastic. Squeeze out the air and close the bag airtight with a knot, thermoseal, or similar. Place the bag into another bag (5.4) together with a sample identification note (see Appendix B), and close the second bag airtight also. Deep-freeze (5.3) the bag whenever possible. Use a refrigerator (5.2) or a cooled thermo-insulated box (5.1) only if the storage period is not too long (48 hours in hot climates).

This represents the "specimen sample".

6.4 Sampling of large-size fish

Determine and note the fork-length, the body weight and sex of the collected specimen.

Separate with a clean rust-free metal knife (5.16) a portion of at least 100 g of muscle tissue. This portion must be at least 5 cm thick so that during sample preparation (7.3) contaminated and dirty tissue can be sliced off. Place each portion into a separate clean bag (5.4), squeeze out the air and close the bag airtight. Place it together with the sample identification note (see Appendix B) into a second bag (5.4) and close it airtight also. Deep-freeze

(5.3) the bag whenever possible, otherwise use a refrigerator (5.2) or a cooled thermo-insulated box (5.1) if the storage period is not too long (48 hours in hot climate).

This represents the "specimen sample".

7. SAMPLE PREPARATION

7.1 Preparatory activities

If necessary, partially thaw deep-frozen samples (6) by placing them overnight in a refrigerator at -2°C to 4°C (partially frozen samples are easier to cut than completely thawed or even fresh samples).

Clean the knives (5.6), the dishes (5.7), the tweezers (5.8), the length-measuring board (5.5) and "weighing plastics" (5.11) with detergent (4.3), rinse with distilled water (4.1) or clean sea water (4.2). Cover the working area with pre-cleaned plastic sheets (5.10). Clean hands carefully with detergent (4.3) and rinse them with distilled water (4.1) or clean sea water (4.2).

NOTE: If hands are cleaned and precautions are taken not to touch the dissected part with hands, bare hands are preferred to hands covered with gloves, since the operator has a much better control of instruments, etc. If possible a clean room should be used for preparatory activities.

7.2 Sample preparation of mussels

Scrape off all foreign materials attached to the outer surface of the shell with a clean plastic knife (knife no. 1) (5.6), to be used only for this purpose or with a strong palstic brush (5.18). Handle the mussels as little as possible.

Rinse each mussel with distilled water (4.1) or alternatively with clean sea water (4.2) and let the water drain off.

Pull out the byssus which extrudes from between the closed shells on the concave side of the shells.

Weigh (5.12) the whole mussel and note the weight.

Insert a second clean plastic knife (knife no. 2) (5.6) into the opening from which the byssus extrudes and cut the adductor muscles by turning the knife as indicated in figure 2 and open the mussel. Do not try to break the mussel open with the knife; if the muscles are cut, the mussel will open easily. Check if the byssus has been eliminated completely; if not, remove the remainder with clean tweezers (5.8).

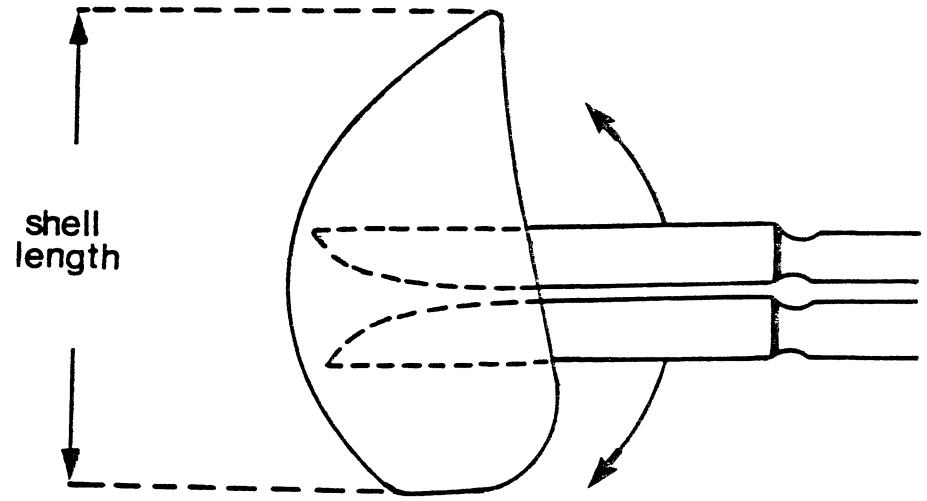

FIGURE 2 : CUTTING THE ADDUCTOR MUSCLE

Rinse the soft part of the mussel in its shells with distilled water (4.1) or clean sea water (4.2).

Loosen all tissue with the second clean knife (knife no. 2) (5.6), remove the soft tissue from the shell with a pair of clean plastic tweezers (5.8) without touching the outer part of the shells, and let all the water drain off.

(a) Single specimen sample: Weigh a clean empty container (5.9) on the balance and note the weight. Then put the soft part of the mussel in it and reweigh. Note the fresh weight of the soft part. Close the container airtight, label it with the sample preparation code. Determine the length of the mussel's shell (figure 2) by placing it with the inner part facing the cm scale (5.13). Note the length of the shell and the weight of the soft part of the mussel.

(b) Composite sample: Fill a container (5.9) of known weight with at least 10 soft parts of mussels prepared as described above. Reweigh the plastic container and note the composite fresh weight of the mussels. Homogenize the specimens in a cleaned blender (5.17), and return the homogenate in the plastic container. Note the total weight again and recalculate the fresh weight of the homogenate. Lable the plastic container with the sample code.

NOTE: When preparing composite samples, use mussels of similar size. The length and weight of each specimen should be determined separately before the soft parts are pooled.

Place several plastic containers in a clean plastic bag (5.4), include an identification note with the containers sample codes, seal the bag airtight and deep-freeze.

This represents the "tissue sample".

7.3 Sample preparation of shrimps

(a) Single specimen sample: Determine the length of the shrimp from rostrum to uropod (see figure 3) using the appropriate length measuring device (5.5). Weigh the shrimp after placing a clean "weighing plastic" (5.11) on the balance (5.12) and note its length and fresh weight.

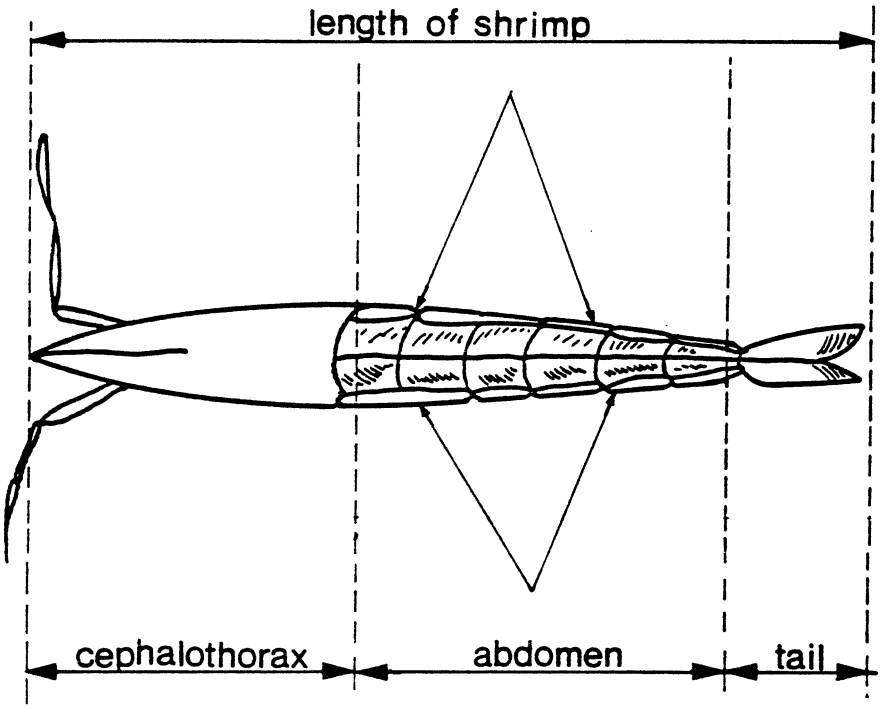

FIGURE 3 : SCHEMATIC DIAGRAM OF A SHRIMP
(arrows indicate where to cut after the legs have been removed)

Separate the abdomen from the cephalothorax and the "tail" (telson and uropod) with a first plastic knife (knife no. 1) taking care that no viscera remain in the abdomen (figure 3). Cut off all legs. Turn the abdomen with the ventral side up and cut with a plastic knife along the edges of the sterinites (ventral exoskeleton); lift the sterinites off with a pair of plastic tweezers and discard.

Loosen with a second clean knife (knife no. 2) the abdomen muscle and lift it from the exoskeleton with a clean pair of tweezers.

Determine and note the sex by examining the gonads.

Transfer the muscle with a clean pair of plastic tweezers (5.8) into a preweighed plastic container (5.9), determine and note the fresh weight of the muscle. Close the container airtight, label it with the sample code, place a suitable number of containers in a plastic bag, add a sample identification note to the containers, and close the bag airtight and deep freeze the samples.

(b) Composite sample: Start sample preparation as described for single specimen sample above taking care to record length, fresh weight, tail muscle weight and the sex of each specimen separately. Reduce the tail muscle(s) of the large specimens to the weight of the smallest tail muscle. A composite sample should not contain less than 6 tail muscles from 6 different specimens of

the same sex and size. Homogenize the tail muscles in a blender (5.17). Transfer the homogenate into a suitable clean container (5.9) which has been weighed empty. Close the container airtight, label it and weigh the container with the homogenate. Note the weight of the homogenate together with the other data in a protocol. Place a suitable number of containers in a plastic bag (5.4), add a sample identification note, close the bag airtight and deep-freeze (5.3) the containers.

This represents the "tissue sample".

NOTE: The concentration of trace metals in a composite sample should represent the mean value of metal concentrations of single specimens. In order to avoid overrepresentation of large specimens, only shrimp of similar size (age) should be used for the preparations of composite samples. In addition, the weight of the tail muscles of all specimens to be included in the composite sample should be reduced to that of the tail muscle of the smallest specimen. As there might be considerable differences in the trace metal content of male and female specimens, use them in separate composite samples.

7.4 Sample preparation for small and medium size fish

(a) Single specimen sample: Determine the fork-length (from tip of snout when the mouth is closed to the apex of the fork of the tail) of fish (figure 4) to the nearest mm on the length-measuring board (5.5). Weigh the fish on a clean "weighing plastic" (5.11) with an accuracy of 0.1% of its total weight and note both the fork-length and the fresh weight of the specimen.

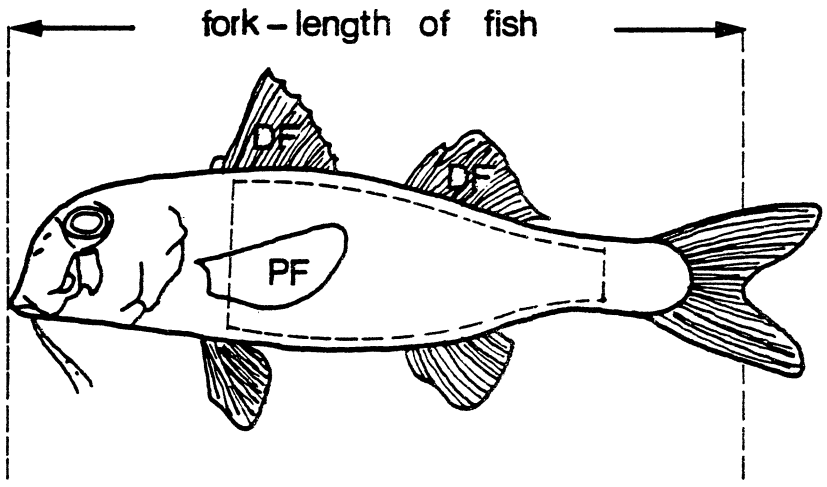

FIGURE 4 : SCHEMATIC DIAGRAM OF A FISH
(PF=pectoral fin, DF=dorsal fins, dashed line shows where the cuts should be made)

Rinse the fish with distilled water (4.1) or clean sea water (4.2) and place it on a clean working surface (5.7). Remove the pectoral fin and cut the skin of the fish with a first knife (5.6) near the dorsal fins, starting from the head to the tail (figure 4).

Cut near the gills across the body, along the ventral edge from the gills to the tail and finally across the body near the tail. These four cuts should be carried out first on one side only taking care not to cut too deep in order to avoid cutting into the viscera and thus contaminating the fillet. It is advisable that a second person hold the fish by the head and tail during this operation.

Pull the skin from the fillet with a pair of tweezers (5.8), taking care that the outer skin does not contaminate the fillet.

With a second clean knife (5.6), cut the fillet from the vertebral column (backbone) starting from the cut near the gills. Lift the fillet with a second clean pair of tweezers (5.8), so that the fillet will not touch the working surface (e.g. the Pyrex dish) or other parts of the fish.

Weigh the fillet in a clean plastic container (5.9) and note its fresh weight.

If one fillet does not yield enough material for analysis, put the fish, skin side upwards, on a clean portion of the working surface (5.3) or on a new working surface and remove the second fillet from the other side of the same fish as described above, add it to the first sample and record their total weight.

Close the container airtight. Identify the container with a code number and/or label, record all data in the protocol and deep-freeze (5.3).

This represents the "tissue sample".

Determine and note the sex of fish by examining the gonads.

NOTE: Comparing the weight of the container holding the fillet sample(s) determined at this point with the weight of the container before the digestion step will show if the tissues have lost moisture during prolonged storage.

(b) Composite sample: Start sample preparation as described for single specimen sample above taking care to record the length, the fresh weight and fillet (sample) weight of each fish separately. Determine and note by examining the gonads the sex of each specimen separately.

Reduce the fillet(s) of the large specimens to the weight of the smallest fillet. A composite sample should not contain less than 6 fillets from 6 different specimens of the same sex and size. Homogenize the fillets in a blender (5.17). Transfer the homogenate into a suitable clean container (5.9) which has been weighed empty. Close the container airtight, label it and weight the container with the homogenate. Note the weight of the homogenate together with the other data in a procotol and deep-freeze (5.3) the container.

This represents the "tissue sample".

NOTE: The concentration of trace metals in a composite sample should represent the mean value of metal concentrations of single specimens. In order to avoid overrepresentation of large specimens, only fish of similar size (age) should be used for the preparation of composite samples. In addition, the weight of the fillets of all specimens to be included in the composite sample should be reduced to that of the fillet of the smallest fish. As there might be considerable differences in the trace metal content of male and female specimens, use them in separate composite samples.

7.5 Sample preparation of large-size fish

If necessary, thaw partially, e.g. overnight in a refrigerator (-2 to 4°C), the subsample taken in the field during sampling (6.4).

Rinse the subsample with distilled water (4.1) or clean sea water (4.2) and place it on a clean working surface (5.7). Remove any skin and bone that may be present. Cut off thin slices from all surfaces with clean plastic knife (5.6) and discard them. Repeat the operation with a second clean knife (5.6) in order to obtain a clean uncontaminated block of homogeneous tissue.

NOTE: It has been recognized that differences in trace metal concentrations may exist between different muscles in large fish, therefore as much information as possible on the actual sample should be recorded.

Transfer the tissue into an airtight container (5.9), close and label it, weigh it, note all data together with data of the subsample in the protocol, and deep-freeze (5.3).

This represents the "tissue sample".

8. SAMPLING AND SAMPLE PREPARATION PROTOCOL

Fill in the sampling and sample preparation protocol (table 1) giving full details in every column. This protocol should be attached to the test report on the determination of trace metals in the analyzed sample.

The following guidelines should be kept in mind when completing the protocol (the numbers refer to those used in table 1):

1.1 Use the scientific name for the species sampled. If necessary indicate subspecies or variety.

1.2 Indicate the name under which the species is known locally.

1.3 Use any code adopted by your institution. Never use the same sample code for more than one sample.

3.2 For samples obtained on fish market, indicate the town (village) where the market is. For samples taken at standard sampling stations or areas, indicate the name (code) of the station or area.

3.3 If the sampling point does not coincide with a standard sampling station or area, it may be advisable to code (name) it, in particular when the sampling point is used more frequently (e.g. a particular fish market). Never use the same sampling point code for more than one sampling point.

3.4 and 3.5 Always indicate the longitude and latitude of the sampling point to the nearest minute. For samples obtained from fish market, enquire about their provenience and try to reflect it also as geographic co-ordinates. Circle either E or W and N or S, as appropriate.

3.6 Give any additional information which may be relevant for the interpretation of the results (e.g. sampling point in vicinity of outfalls or similar).

4.1 Indicate the difference between data given under 2 and 5.

4.2 Mark the storage conditions used. If none of them applicable, give additional explanations in 4.3.

6.2 Identify sex of the specimen whenever possible. As for specimen length, determine shell length for mussels, fork length for fish and total length for shrimp as indicated in figures 2, 3, and 4. Specimen weight always refers to the fresh weight of the whole mussel, of the whole shrimp and of the whole fish. Note that sample weight, in the case of mussels, refers to the total weight of soft tissues. In the case of shrimp, the sample weight refers only to the fresh weight of the muscle, and in the case of fish, to the fresh weight of the fillet or of the combined weight of fillets removed from the same fish.

6.3 Whenever possible use six or more specimens of the same sex and size (age) in preparing composite samples. Mean length and weight refers to the arithmetical mean of the weight and length of individual specimens, as explained above. Always calculate the standard deviations.

Table 1: Sampling and Sample Preparation Protocol

1. Sample (specimen)

1.1 Scientific name:_____

1.2 Common name:_____

1.3 Sample code:_____

2. Date of sampling: day_____; month_____; year_____

3. Sampling point

3.1 Country:_____

3.2 Type of sampling point:_____fish market;

_____sampling area/station

3.3 Sampling point code:_____

3.4 Longitude: _____° _____' E or W

3.5 Latitude: _____° _____' N or S

3.6 Conditions at sampling point which may be relevant for the interpretation of results:

_____

_____

_____

4. Sample storage

4.1 Duration of storage:_____hours; _____days

4.2 Storage: deep-freezing_____; cooling_____

4.3 Factors relevant to sample storage which may be important for the interpretation of results:

_____

_____

_____

5. Date of sample preparation: day_____; month_____; year_____

6. Sample preparation

6.1 Tissue type (kind)_____

6.2 Single specimen sample: sex____; specimen length_____cm;

Appendix A

Preparing plastic tweezers

Methylmetacrylate of 4 mm thickness has been found to be very useful as it has the right elasticity. If thinner or thicker material has to be used, either the strips from which the tweezers are to be made are cut wider or narrower. The easiest way to heat the plastic and bend it is with a hot air blower used for forming plastics. A drying oven can be used also. However, it is much more difficult to make tweezers by heating the plastic in an oven since the plastic twists easily.

Materials:

- sheets of acrylic (methylmetacrylate) resin; 4 mm thick (trade names: e.g. Perspex, Flexiglas, Lucite);
- a plastic tube, about 40 mm in diameter.

Equipment:

- hot air blower (300-350°C) used for molding plastics, or Drying oven (135-140°C).

Procedure:

(a) With a hot air blower

- cut from the sheet with an electric or a hand saw strips of about 10 mm width and 250 mm length;
- heat about a 60 mm long part in the middle of the strip so that it bends easily. Bend it around the plastic tube carefully in order to make both ends meet. Cool the plastic with cold water;
- sharpen the ends with a file and roughen the inside of the tweezers so that they grip well;
- wash the tweezers carefully with detergents and rinse them with distilled water.

(b) With a drying oven

- place the plastic strip on a clean piece of wood in a drying oven (135-140°C) until it becomes soft;
- lift the strip at one end with a pair of tweezers and bend it around the plastic tube without letting the tweezer tips meet;
- cool the tips by dipping them in a beaker of clean cold water and afterwards bend the ends of the tweezer so that the tips meet;
- prepare the ends of the tweezers as described earlier.

Appendix B

Sample indentification note

A standard sample identification note should contain the following data:

- sample code (the same code should be used in 1.3 of the Sampling and Sample Preparation Protocol; see table 1);
- species name (important in particular whenever storage of sample may create difficulties in determining the species);
- sampling date;
- sampling location (given as sampling point code, if possible; see 3.3 of table 1);
- collector's (sampler's) name;

Example:

AN 435
Mytillus galloprovincialis
3 March 1982
F 17
D. Degobbis

Annex III:

HELCOM

Manual for marine monitoring in the COMBINE programme.

ANNEX B-12 Technical note on the determination of heavy metals and persistent organic compounds in biota.

ANNEX B-12 TECHNICAL NOTE ON THE DETERMINATION OF HEAVY METALS AND PERSISTENT ORGANIC COMPOUNDS IN BIOTA

ANNEX B-12, APPENDIX 1. TECHNICAL NOTE ON BIOLOGICAL MATERIAL SAMPLING AND SAMPLE HANDLING FOR THE ANALYSIS OF PERSISTENT ORGANIC POLLUTANTS (PAHS, PCBS AND OCPS) AND METALLIC TRACE ELEMENTS

1. GENERAL PRINCIPLES

Muscle tissue or liver of fish have to be dissected while they are in good condition. If biological tissue deteriorates, uncontrollable losses of determinands or cross-contamination from other deteriorating tissues and organs may occur. To avoid this, individual fish specimens must be dissected at sea if adequate conditions prevail on board, or be frozen immediately after collection and transported frozen to the laboratory, where they are dissected later.
If the option chosen is dissection on board the ship, two criteria must be met:
1. The work must be carried out by personnel capable of identifying and removing the desired organs according to the requirements of the investigations; and 2. There must be no risk of contamination from working surfaces or other equipment.

2. TOOLS AND WORKING AREA

Crushed pieces of glass or quartz knives, and scalpels made of stainless steel or titanium are suitable dissection instruments.

Colourless polyethylene tweezers are recommended as tools for holding tissues during the dissecton of biological tissue for metallic trace element analysis. Stainless steel tweezers are recommended if biological tissue is dissected for analysis of chlorinated biphenyls (PCBs), organochlorine pesticides (OCPs) and polunuclear aromatic hydrocarbons (PAHs).
After each sample has been prepared, including the samples of different organs from the same individual, the tools should be changed and cleaned.

The following procedures are recommended for cleaning tools used for preparing samples:
1) for analysis of metallic trace elements

- a) Wash in acetone or alcohol and high purity water.
- b) Wash in HNO_3 (p.a.) diluted (1+1) with high purity water. Tweezers and haemostates in diluted (1+6) acid.

- c) Rinse with high purity water.

2) for analysis of CBs and OCPs
- a) Wash in acetone or alcohol and rinse in high purity water.

The glass plate used during dissection should be cleaned in the same manner. The tools must be stored dust-free when not in use.

The dissection room should be kept clean and the air should be free from particles. If clean benches are not available on board the ship, the dissection of fish should be carried out in the land-based laboratory under conditions of maximum protection against contamination.

3. FISH MUSCLE AND LIVER SAMPLES DISSECTION

For fish analysis, commercial catches can be used if fish transport to the laboratory does not take longer than 24 hours. The fish must be transported on ice. The dissection then takes place at the laboratory.

For analysis of **fish muscle**, the epidermis and subcutaneous tissue should be carefully removed from the fish. Samples should be taken under the red muscle layer. In order to ensure uniformity of samples, the **right** side **dorso-lateral muscle** should be taken as the sample. If possible, the entire right dorsal lateral filet should be used as a uniform sample, from which subsamples can be taken after homogenizing for replicate dry weight and contaminant determinations. If, however, the amount of material obtained by this procedure is too large to handle in practice, a specific portion of the dorsal musculature should be chosen for the sample. It is recommended that the portion of the muscle lying directly under the first dorsal fin should be utilised in this case. As both fat and water content vary significantly in the muscle tissue from the anterior to the caudal muscle of the fish (Oehlenschläger, 1994), it is important to obtain the same portion of the muscle tissue for each sample.

To sample **liver tissue**, the liver must be identified in the presence of other organs such as the digestive system or gonads (Harms and Kanisch, 2000). The appearance of the gonads will vary according to the sex of the fish and the season. After opening the body cavity with a scalpel, the connective tissue around the liver should be cut away and as much as possible of the liver is cut out in a single piece together with the gall bladder. The bile duct is then carefully clamped and the gall bladder dissected away from the liver.

When fish samples which have been frozen at sea are brought to the laboratory for analysis, they should be dissected as soon as the tissue has thawed sufficiently. The dissection of fish is easiest when the material, at least the surface layers of the muscle tissue, is half frozen. For dissection of other organs, the thawing must proceed further, but it is an advantage if, for example, the liver is still frozen. It must be noted that any loss of liquid or fat due to improper cutting or handling of the tissue makes the determinations of dry weight and fat content, and consequently the reported concentrations of determinands, less accurate.

After muscle preparations, the liver should be completely and carefully removed while still partly frozen to avoid water and fat loss. Immediately after removing it from the fish, the liver should be returned to the freezer so that it will be completely frozen prior to further handling. This is particularly important for cod liver.

4. SHELLFISH SAMPLING

The blue mussel *(Mytilus edulis)* occurs in shallow waters along almost all coasts of the Baltic Sea. It is therefore suitable for monitoring in near shore waters. No distinction is made between

M. edulis, *M. gallopovincialis,* and *M. trossulus* because the latter species fills a similar ecological niche. A sampling size range of 20–70 mm shell length is specified to ensure availability throughout the whole maritime area.

Two alternative sampling strategies can be used: sampling to minimise natural variability and length-stratified sampling. Only details of length-stratified sampling are described in this document, as this strategy is used in monitoring programmes for temporal trends of contaminants in biota.

For shellfish, the upper limit of shell length should be chosen in such a way that at least 20 mussels in the largest length interval can easily be found. The length stratification should be determined in such a way that it can be maintained over many years for the purposes of temporal trend monitoring. The length interval shall be at least 5 mm in size. The length range should be split into at least three length intervals (small, medium, and large) which are of equal size after log transformation.

Mussels are collected by a bottom grab and selected onboard. The number of specimens selected for analysis depends on their length, e.g. 80-100 individuals are necessary to suffice material within the length range 4-5 cm.

5. STORAGE OF FISH AND MUSSEL SAMPLES

Material from single fish specimens should be packaged and stored individually.

- Samples for analysis of metallic trace elements can be stored in polyethylene, polypropylene, polystyrene or glass containers.

- Samples for analysis of CBs and OCPs should be packaged in precleaned aluminium foil or in precleaned glass containers.

Liver tissue can deteriorate rather rapidly at room temperature. Consequently, samples should be frozen as soon as possible after packaging. They can be frozen rapidly by immersion in liquid nitrogen or blast freezing, but both these techniques need care. Whatever system is used, freezing a large bulk of closely packed material must be avoided. The samples in the centre will take longer to cool and will therefore deteriorate more than those in the outer layer.
Once frozen, samples can be stored in a deep freezer at temperatures of -20$_{o}$C or below. Frozen liver tissue should not be stored longer than six months, while lean muscle tissue can be stored up to two years. Each sample should be carefully and permanently labelled. The label should contain at least the sample's identification number, the type of tissue, and the date and location of sampling.

Mussels should be shucked live and opened with minimal tissue damage by detaching the adductor muscles from the interior of at least one valve. The soft tissues should be removed and homogenised as soon as possible, and frozen in glass jars at -20 °C until analysis. Mussel tissue for trace metal determination is homogenised and decomposed in a wet state while for persistent organic pollutants determination it is homogenised and water is removed by freeze-drying. Frozen liver tissue should not be stored longer than six months, while lean muscle tissue can be stored up to two years. Each sample should be carefully and permanently labelled. The label should contain at least the sample's identification number, the type of tissue, and the date and location of sampling.

OSPAR COMMISSION

CEMP Guidelines for Monitoring Contaminants in Biota

CEMP Guidelines for Monitoring Contaminants in Biota

(OSPAR Agreement 1999-02)

1. Introduction

1. These guidelines concern the sampling and analysis of contaminants in fish, shellfish and seabird eggs. They are suitable for hazardous substances: trace metals and organic compounds including chlorinated compounds (such as chlorobiphenyls, DDT and metabolites, HCH isomers, HCB and dieldrin), parent and alkylated PAHs, brominated flame retardants such as polybrominated diphenyl ethers (PBDEs) and hexabromocyclododecane (HBCD), perfluorinated compounds (PFCs), organotin compounds (TBT and its breakdown products), dioxins, furans and dioxin-like PCBs. Technical details relating to sampling, analysis, QA and reporting are given in Technical Annexes 1 and 3-9 (organic contaminants) and Technical Annex 2 (metals).

2. Purposes

2. Monitoring of contaminants in marine biota in the North-east Atlantic Ocean is performed within the framework of OSPAR as the regional convention for the protection of the marine environment of this area. The objectives of monitoring and assessment are described in the Joint Assessment and Monitoring Programme (JAMP) under the Hazardous Substances Strategy, providing the basis for the monitoring programme of chemicals for priority action, and hazardous substances in general, and addressing the following issues (see JAMP Theme H):

a. What are the concentrations of hazardous substances in the marine environment? Are those hazardous substances monitored at, or approaching, background levels for naturally occurring substances and close to zero for man-made substances? How are the concentrations changing over time? Are the concentrations of either individual substances or mixture of substances such that they are not giving rise to pollution effects?

b. What are the sources, what are the levels of discharges, emissions and losses and what are the pathways to the marine environment for individual OSPAR chemicals for priority action and other hazardous substances listed by e.g. the Stockholm Convention and the MSFD? Are the discharges, emissions and losses from sources of these substances to the marine environment continuously decreasing, and are they moving towards the target of cessation?

3. The existing level of marine contamination in different parts of the convention area can be assessed by spatial distribution monitoring. Monitoring contaminant concentrations in fish, shellfish and seabird eggs can be used to indicate large-scale regional differences in contamination.

4. The measured levels can be compared to background or close to background reference conditions as well as to levels describing the thresholds above which negative effects on living resources and marine life are expected. OSPAR monitoring can assist member states of the European Union to fulfil their obligations under relevant EU-directives, namely the Marine Strategy Framework Directive (MSFD, 2008/56/EC) and the Water Framework Directive (WFD, 2000/60/EC) and related directives like the WFD daughter directive on Environmental Quality Standards in the field of water

policy (2008/105/EC), to assess whether certain regions or sub-regions, have reached or failed to reach Good Environmental Status.

5. The effectiveness of measures taken for the reduction of marine contamination can be assessed by performing trend monitoring. Changes in contaminant inputs are reflected in the concentrations of contaminants in biota over time. The statistical assessment of a trend over a longer period also supplies a more reliable assessment for the status within a certain period or the last measured year and therefore also for the assessment of the actual status, as the within and between year variability is thereby taken into account.

6. An integrated approach is needed to assess harm to living resources and marine life. The role of chemical measurements in integrated chemical and biological effects monitoring programmes is:

i. to identify sites where contaminant-specific biological effects programmes should be applied;

ii. to investigate the chemical cause of observed biological effects;

iii. How to improve and extend OSPAR's monitoring framework and better link it with the understanding of biological effects and ecological impacts of individual substances and the cumulative impacts of mixtures of substances.

3. Quantitative objectives

3.1 Temporal trends

7. Before starting to interpret results from statistical time series analyses it is essential to know with what power temporal changes in concentration could be detected (*i.e.* the chances of revealing true trends in concentration within the matrices investigated). When no trend is found, it is essential to know whether this indicates a stable situation or that the sampling strategy is too poor to detect even major changes in the contaminant load to the environment. One approach for solving this problem would be to estimate the power of the time series based on the 'random' between-year variation. Alternatively the lowest detectable trend could be estimated at a fixed power to represent the sensitiveness of the time series. It should be stressed that the power estimate must be interpreted with great caution. A matrix showing a very high power is not necessarily a good matrix for monitoring. If the matrix analysed does not respond to the environmental changes being monitored, the between-year variation would probably be low and consequently the power high. Another problem is that a single outlier could ruin an estimate of the between-year variation. Bearing these difficulties in mind, and as an example for the purpose of trend monitoring, the quantified objective could be stated, including the following information:

- the annual change which the programme should be able to detect
- the time period
- the power at a set significance level (α) with a one-sided test.

A typical example which has been used previously is the ability to detect an annual change of 5% within a period of 10 years at a power of 90% at a significance level (α) of 5% with a one-sided test. For many areas, however, due to the decline of contaminant concentrations which has been observed this approach is no longer realistic, so that the annual change to be detected should be lower and the time period longer, e.g. a 2% fall over a time period of 30 years.

8. The necessary or possible power of a monitoring programme will vary with the purpose of the investigation and with the contaminant, matrix and area being investigated. It is thus not possible to give fixed values for all situations. It is the duty of the programme manager to specify the size of the changes the monitoring programme is expected to identify and at what power, or for the programme executor to estimate what it is possible to achieve. It is, however, essential that the quantitative objectives are determined before any monitoring programme is started.

9. Due to the decrease of concentrations of many substances in the last two decades, for certain substances and areas it is not any longer possible to detect significant changes which can be associated with a trend. Monitoring is serving in this case for the assessment of status and to detect any deterioration. Depending on the magnitude of natural variability, it may also be possible to reduce the monitoring effort and to change from annual sampling to longer intervals without loss of relevant information.

3.2 Spatial distribution

10. A spatial distribution monitoring programme should enable Contracting Parties to determine the representativeness of their monitoring stations with regard to spatial variability in contaminant concentrations. This would include a definition of the monitoring area and some understanding of the randomness of the monitoring programme. It can also deliver information useful to distinguish between areas of different character and to define water bodies or areas which should be assessed separately. The purpose and quantitative objectives could be expressed as follows, for example:

- Purpose: to identify whether an area has elevated contaminant concentrations, possibly due to anthropogenic inputs.
- Quantitative Objective: to detect a difference of 10 μg/kg between the average contaminant concentrations in area A and the average contaminant concentrations in control area B with a power of 90%.

or

- Purpose: to map the spatial distribution of contaminants.
- Quantitative Objective: for the precision of an interpolated point on the map to be at worst 10%.

or

- Purpose: to locate “hot spots”.
- Quantitative Objective: for the probability of missing a circular “hot spot” of radius 0.5 km to be no greater than 5%.

11. For more detailed information about statistical analyses of monitoring data see Nicholson *et al*., (1997).

12. Spatial distribution monitoring is supplying relevant information for assessing different water bodies and areas both for the purposes of the EU-MSFD and the EU-WFD. Following the sampling and analytical techniques as described in this guideline and its technical annexes will assist in avoiding significantly deviating monitoring results for neighbouring regions with comparable conditions, which consequently affects the assessment of the (good) environmental status.

3.3 Qualitative objectives

13. The quantitative results will be used to perform the assessment of the status of the marine environment with regard to hazardous substances. Further information on the assessment procedure,

the classification schemes and the threshold values used for distinguishing between the different classes from e.g. unacceptable to excellent or Good Environmental Status (WFD, MSFD) being achieved or not, can be found in the relevant OSPAR agreements and EC Directives and Decisions.

4. Sampling strategy

4.1 General

14. The sampling strategy should take into account the specific objectives of the monitoring programme, including the quantitative objectives. Natural variability between the samples should be reduced by an appropriate sampling design and the performance of the analytical procedures (*i.e.* the accuracy and precision) must be adequate to meet the objectives. A preliminary/exploratory sampling programme will provide useful information prior to designing the final programme. Statistical procedures must be taken into account to estimate the number of samples and sampling sites required to achieve a satisfactory level of confidence. More guidance on this topic is given by Gilbert (1987).

15. In more exploratory studies, data may be statistically analysed in several ways for several purposes. However there should still be a clear understanding of what must be measured from what population and how the samples are to be selected. The sampling strategy is an intrinsic component of the data, and may limit their use and interpretation. Quantitative objectives for a selected primary purpose should also be established for exploratory studies.

16. When conducting an integrated chemical and biological effects sampling programme, the purpose of the chemical measurements is both to be assessed against limit values and to aid the interpretation of the biological effects measurements in terms of identifying the chemical causes of the biological effects and establishing concentration responses. In such cases, the sampling strategies used should comply with those in the biological effects monitoring guidelines and the monitoring guidelines for the relevant chemical determinands. The analytical methods used should be as specified in the relevant chemical guidelines.

17. With regard to the choice of monitoring parameters, the sampling strategy should cover the demands of as many purposes as possible for both OSPAR and the EU-MFSD, and in particular the compounds determined should address the indicators under descriptor 8 of the MSFD, the species and tissues and, where possible, the selection of sampling sites in coastal areas should also meet the requirements of the EU Water Framework Directive.

4.1.1 Species

18. Prior to monitoring, it is important to be clear about:

- the target population (e.g. cod from a specified length-range caught in a specified area at a specified time);
- the sampled population, if this differs from the target population (e.g. if fishing is restricted within particular areas);
- the sampling unit (e.g. an individual fish or pooled samples);
- the observed variable (e.g. mercury concentration on a wet weight basis in a subsample of tissue from individual fish muscle).

19. When selecting the species to be monitored for chemical contaminants, some basic prerequisites should be considered. Where possible the organisms should:

- reflect changes in the concentration of contaminants in the surrounding environment;
- for a given species, have similar bioconcentration factors throughout the Maritime Area;

- accumulate the contaminant without being seriously affected by the concentrations encountered in the marine environment;
- be representative of the study area;
- be abundant throughout the study area;
- be of reasonable size, giving adequate amounts of tissue for chemical, biochemical and physiological analyses; restrictions to this may occur on different preconditions for performing the different tests and analytical methods;

in particular for shellfish and for investigations exceeding the demands of "routine" monitoring:

- be easy to sample and hardy enough to survive in the laboratory, thus allowing:
  - defecation before analysis (if desired);
  - laboratory studies of contaminant uptake;
  - studies verifying biological field observations.

4.2 Sampling strategy for temporal trend monitoring

4.2.1 Species and sampling

20. The species of interest can only be selected in the light of information on the fish and shellfish stock and on the seabird population composition and migration pattern.

21. For fish and shellfish, sampling to minimise natural variability is the preferred strategy, see table 1. Length-stratified sampling may be maintained where it has been successfully applied in the past. Recommendations for species, size etc. are given in Table 2. Where conditions have changed such that length stratified sampling cannot be sustained any longer, or the indicator species has to be changed due to changing abundance, it will be appropriate to sample with a view to minimising natural variability within the sample.

For shellfish, a sample should be collected with the number of individuals large enough to be divided into at least 3 equal pools with each pool consisting of at least 20 animals and enough soft tissue for all analyses. The length of the individuals collected should to the extent possible, be constant from year to year at each station, or should at least fall within a very narrow range, e.g. within 5 mm. To reflect recent levels of contamination, young individuals should be chosen. In selecting the sample, care should be taken that it is representative of the population and that it can be obtained annually. Recommendations for sampling to minimise natural variability are given in Table 1. If a Contracting Party decides to change its sampling strategy, data from the old and new programmes should not be compared without first checking the compatibility of the two approaches. More detailed information about length-stratified sampling and sampling to minimise natural variability is given in Technical Annexes 1 and 2 (Agreement 1999-2).

Table 1: Sampling to minimise natural variability

Species	Number	Size[1]	Age	Sex[2]	Tissue
Shellfish					
Mussel *Mytilus edulis* or *M. galloprovincialis*	3 pools of 20	Narrow length range	1-2 years	-	Whole soft body
Pacific oyster *Crassostrea gigas*		Narrow length range	2 years	-	Whole soft body
Flatfish					
Dab *Limanda limanda*	At least 12	Narrow length range	1-3 years	Single sex, females*	Muscle for Hg. Liver for all other determinands
Flounder *Platichthys flesus*	At least 12	Narrow length range	1-3 years	Single sex, females*	Muscle for Hg. Liver for all other determinands
Plaice *Pleuronectes platessa*	At least 12	Narrow length range	1-3 years	Single sex, females*	Muscle for Hg. Liver for all other determinands
Roundfish					
Cod *Gadus morhua*	At least 12	Narrow length range	Preferably 1-3years**		Muscle for Hg. Liver for all other determinands
Whiting *Merlangius merlangus*	At least 12	Narrow length range	2-3 years	Single sex, preferably females	Muscle for Hg. Liver for all other determinands
Hake *Merluccius merluccius*	At least 12	Narrow length range	2-3 years	Single sex, preferably females	Muscle for Hg. Liver for all other determinands
Herring *Clupea harengus*	At least 12	Narrow length range	1-2 years		Muscle for organic contaminants and Hg. Liver for other trace metals.
Eel pout *Zoarces viviparus*	At least 12	Narrow length range	2-3 years	Single sex, preferably females	Muscle for Hg. Liver for all other determinands
Seabird eggs					

[1] "Narrow length range" means that the length of the individuals collected should be constant from year to year at each site or should at least fall within a very narrow range. The length range could however vary between sites and hence is not specified in the table.

[2] The same sex should be sampled each year.

Species	Number	Size[1]	Age	Sex[2]	Tissue
Common tern					
Sterna hirunda	10 [3]	-	1-5 days incubation	-	Whole egg content
Oyster catcher					
Haematopus ostralegus	10 [4]	-	1-5 days incubation	-	Whole egg content
Guillemot					
Uria aalge	10 [4]	-	1-5 days incubation		Whole egg content

* As for flatfish sex can be determined easily. If possible, only females should be chosen, as males show higher variation in age distribution and contaminant concentrations at comparable length

** Smaller fish should, if possible be selected to reflect recent influence and reduce the effects of sex, as age determination without dissection is not possible, When the amount of tissue(s) needed for all investigations within an integrated chemical and biological effects monitoring programme is not sufficient, selection of larger fish may be appropriate.

Table 2: Length-stratified sampling

Species	Number	Size (cm)	Tissue
Shellfish			
Mussel *Mytilus edulis* or *M. galloprovincialis*	3 pools of 20	3-6	Whole soft body
Pacific oyster *Crassostrea gigas*	10 ± 10%	9-14 (2 years of age)	Whole soft body
Flatfish			
Dab *Limanda limanda*	25 to 20 individuals, or 15 if justified, or 5 batches of 5 individuals	18-30	Muscle for Hg. Liver for all other determinands
Plaice *Pleuronectes platessa*	25 to 20 individuals, or 15 if justified, or 5 batches of 5 individuals	20-30	Muscle for Hg. Liver for all other determinands
Flounder *Platichthys flesus*	25 to 20 individuals, or 15 if justified, or 5 batches of 5 individuals	15-35	Muscle for Hg. Liver for all other determinands
Roundfish			
Cod *Gadus morhua*	25 to 20 individuals, or 15 if justified, or 5 batches of 5 individuals	25-40	Muscle for Hg. Liver for all other determinands
Whiting *Merlangius merlangus*	25 to 20 individuals, or 15 if justified, or 5 batches of 5 individuals	20-35	Muscle for Hg. Liver for all other determinands
Hake *Merluccius merluccius*	25 to 20 individuals, or 15 if justified, or 5 batches of 5 individuals	20-35	Muscle for Hg. Liver for all other determinands

[3] One egg taken randomly from each of 10 clutches.

[4] The eggs should be collected as early as possible to avoid collecting replacement eggs.

4.2.2 Sampling area

Fish

22. To improve the power of the programme, samples should be collected from areas characterised by relatively low natural variability. The spatial representativeness of the area should be known.

Shellfish

23. The spatial representativeness of the area should be known. Samples should preferably be collected from sub-tidal regions, otherwise as near to the low water spring tide level as possible. They should be collected as near to the same depth and exposure (i.e. in terms of light and wave action) as possible in order to reduce variability in contaminant uptake. The boundary of the sampling site must be specified. At locations where suitable natural populations are not available, caged mussels may be used.

Seabird eggs

24. Sampling sites should reflect important breeding areas. To collect the necessary number of eggs over the period of the monitoring programme sampling sites should be chosen where sufficient numbers of pairs of birds can be expected to breed for the required number of years.

4.2.3 Sampling frequency

25. Sampling should be annual. In cases where no trend can still be observed, no local source is influencing the sampling site and natural variability is the dominant reason for variations in concentrations, it may also be possible to reduce the monitoring effort and to change from annual sampling to longer intervals.

4.2.4 Sampling period

Fish

26. Sampling should take place when fish are in a stable physiological state and, in any case, outside the period of spawning. See Table 3 for further guidance. Sampling should take place within a fixed time span each year (e.g. mid August-mid October for fish in the southern North Sea).

Shellfish

27. Sampling should take place during late autumn/early winter, when mussels are in a more stable physiological status, and in any case during a period before spawning. Gametogenesis and spawning generally occur in late spring to early summer, when individuals may lose up to 50% of their soft tissue weight. Table 3 give guidance on spawning periods.

Seabird eggs

28. Eggs should be sampled during the species-specific, year-specific and site-specific peak of the first laying cycle within the year. This generally occurs in May/June. Only fresh eggs should be taken from full clutches. For each species, site and year, 10 eggs should be sampled with one egg taken randomly from each of 10 clutches from the first laying cycle within the year.

4.3 Sampling strategy for spatial distribution monitoring

29. For each spatial distribution programme, the species and sampling strategy, including quantitative objectives, should be clearly defined to ensure that the purpose of the programme is fulfilled.

4.3.1 Species and sampling

30. Table 4 gives the recommended species and number of fish, shellfish and seabird eggs, the size of individual fish and shellfish and the tissue type. However, the number of fish and the number of stations as well as whether individuals or pooled samples should be analysed will depend on the specific objectives of the monitoring programme. In order to reduce the number of analyses which must be performed, pooled samples may be used. Additional, more specific, guidelines on the treatment of samples may need to be prepared by the programme managers.

Table 3: Time of spawning season. Spawning season varies regionally due to climate conditions and in the case of fish it is recommended to use FishBase (http://www.fishbase.org/search.php) in order to find the specific spawning time for a particular sea area.

Species	Spawning season	Reference
Shellfish		
Mussel		
Mytilus edulis *M. galloprovincialis*	Spawning throughout the year but normally peaks in springtime and autumn	http://www.ukmarinesac.org.uk/communities/biogenic-reefs/br4_4.htm
Pacific oyster	Summer months (above 20 °C)	http://www.fao.org/fishery/culturedspecies/Crassostrea_gigas/en
Crassostrea gigas		
Flatfish		
Dab		
Limanda limanda	January-August	http://www.fishbase.org/Reproduction/SpawningList.php?ID=695&GenusName=Limanda&SpeciesName=limanda&fc=440&StockCode=711
Plaice		
Pleuronectes platessa	January-June	http://www.fishbase.org/Reproduction/SpawningList.php?ID=1342&GenusName=Pleuronectes&SpeciesName=platessa&fc=440&StockCode=1360
Flounder		
Platichthys flesus	January-June	http://www.fishbase.org/Reproduction/SpawningList.php?ID=1341&GenusName=Platichthys&SpeciesName=flesus&fc=440&StockCode=1359
Roundfish		
Cod

[5] Please use information on the actual timing of spawning in your sampling area. It is recommended to use Fishbase www.fishbase.org:

Whiting *Merlangius merlangus*	January-September	http://www.fishbase.org/Reproduction/SpawningList.php?ID=29&GenusName=Merlangius&SpeciesName=merlangus&fc=183&StockCode=39
Hake *Merluccius merluccius*	December-August	http://www.fishbase.org/Reproduction/SpawningList.php?ID=30&GenusName=Merluccius&SpeciesName=merluccius&fc=184&StockCode=40

Table 4: Spatial distribution sampling

When monitoring for trends at various sites, refer to tables 1 and 2

Species	Recommended Number	Size (cm)	Tissue
Shellfish			
First choice Mussel *Mytilus edulis* or *M. galloprovincialis*	50 [footnote 4] ± 10%	3-6	Whole soft body
Second choice[1] Pacific oyster *Crassostrea gigas*	10 [footnote 4] ± 10%	9-14 (2 years of age)	Whole soft body
Flatfish			
First choice Dab *Limanda limanda*	20 to 25 individuals, or 15 if justified, or 5 batches of 5 individuals	18-30	Muscle for Hg. Liver for all other determinands
Second choice[1] Flounder *Platichthys flesus*	20 to 25 individuals, or 15 if justified, or 5 batches of 5 individuals	15-35	Muscle for Hg. Liver for all other determinands
Roundfish			
First choice Cod *Gadus morhua*	20 to 25 individuals, or 15 if justified, or 5 batches of 5 individuals	>20	Muscle for Hg. Liver for all other determinands
Second choice[1] Whiting *Merlangius merlangus*	20 to 25 individuals, or 15 if justified, or 5 batches of 5 individuals	20-35	Muscle for Hg. Liver for all other determinands
Hake *Merluccius merluccius*	20 to 25 individuals, or 15 if justified, or 5 batches of 5 individuals	20-35	Muscle for Hg. Liver for all other determinands
Seabird eggs			
Common tern *Sterna hirunda*	10 [footnote 2]	-	Whole egg content

http://www.fishbase.org/Reproduction/SpawningList.php?ID=69&GenusName=Gadus&SpeciesName=morhua&fc=183&StockCode=79

Oyster catcher		-	
Haematopus ostralegus	10 footnote 2		Whole egg content
Guillemot		-	
Uria aalge	10 footnote 3		Whole egg content

1 Where first choice species is not available.

2 One egg taken randomly from each of 10 clutches.

3 The eggs should be collected as early as possible to avoid collecting replacement eggs.

4 The number of specimens can be adjusted upwards to assure ample sample material for the expected analysis, depending on the actual size class available.

4.3.2 Sampling area

Fish

31. Samples should be collected from as many locations as necessary to fulfil the objectives of the programme, taking into account the representativeness of the area with regard to spatial variability in contaminant concentrations.

Shellfish

32. Samples should be collected from as many locations as necessary to fulfil the objectives of the programme, taking into account the representativeness of the area with regard to spatial variability in contaminant concentrations. Samples should preferably be collected from sub-tidal regions, otherwise as near to the low water spring tide level as possible. They should be collected as near to the same depth and exposure (i.e. in terms of light and wave action) as possible in order to reduce variability in contaminant uptake. The boundary of the sampling site must be specified. At those locations where suitable natural populations are not available, caged mussels may be used.

Seabird eggs

33. Sampling sites should reflect important breeding areas. To collect the necessary number of eggs over the period of the monitoring programme sampling sites should be chosen where sufficient numbers of pairs of birds can be expected to breed for the required number of years. Both coastal sites adjacent to the open sea and known “hot spots” such as estuaries should be included.

4.3.3 Sampling period

Fish

34. Sampling should take place when fish are in a stable physiological state and, in any case, outside the period of spawning. See Table 3 for further guidance.

Shellfish

35. Sampling should take place during late autumn/early winter when mussels are in a more stable physiological state and, in any case, during a period before spawning. Gametogenesis and spawning generally occur in late spring to early summer, when individuals may lose up to 50% of their soft tissue weight. Table 3 give guidance on spawning periods.

Seabird eggs

36. Eggs should be sampled during the species-specific, year-specific and site-specific peak of the first laying cycle within the year. This generally occurs in May/June. Only fresh eggs should be taken

from full clutches. For each species, site and year, 10 eggs should be sampled with one egg taken randomly from each of 10 clutches from the first laying cycle within the year.

4.4 Sampling strategy for biological effects monitoring

37. The sampling strategy will, in all cases, depend on the biological effect(s) to be studied. No general guidelines can therefore be given. For more details see specific guidelines (References: OSPAR Guidelines for General Biological Effects Monitoring. OSPAR Ref. No. 1997-7 and Guidelines for contaminant specific biological effects monitoring. OSPAR Ref. No. 2008-9).

5. Field sampling and sampling equipment

5.1 Fish

38. Fish can be sampled from either research vessels or commercial vessels. The former is the preferred option, since research vessels are likely to have better facilities for processing and storing scientific samples. In both cases, the following precautions must be taken when selecting samples from the trawl catch to ensure that contamination is kept to a minimum:

- trained personnel must be present when a trawl comes on board to ensure that the sample can be isolated from possible sources of contamination during the release of fish from the net;
- fish which are visibly damaged or in bad condition must not be selected;
- clean containers should be available on deck to hold the samples temporarily before they are taken to the ship's laboratory. Containers used for holding fish collected from the ship's normal trawling operations must not be used;
- personnel must wear clean gloves when the samples are taken from the net. The samples should be transferred to the ships laboratory as quickly as possible and rinsed with clean sea water to remove any material adhering to the surface;
- equivalent precautions should be taken on modern fisheries research vessels, when the catch is released from the net directly into facilities below deck;
- only material suitable for the subsequent analyses should be retained for storage (see Technical Annexes 1 and 2 for guidance on appropriate storage containers).

39. Suitable fishing gear should be used to ensure that the catch reflects the target population. The trawling time should not exceed one hour and the trawling speed should be as slow as possible to reduce damage and stress to the fish. Details of the requirements for recording the relevant sampling parameters are given in Technical Annexes 1 and 2.

5.2 Shellfish

40. Only those individuals that are free of fouling and bored shells should be sampled. When collecting mussels by ship, a commercial mussel dredge can be used. When collecting mussels by hand, personnel should wear gloves. Clean containers consisting of material suitable for the subsequent

analyses should be used for transportation. Details of the requirements for recording the relevant sampling parameters and information on sampling methods are given in Technical Annexes 1 and 2.

5.3 Seabird eggs

41. The equipment required, details of the requirements for recording the relevant sampling parameters, and information on sampling methods are specified in Technical Annexes 1 and 2.

6. Storage and pre-treatment

42. Samples should be analysed as soon as practicable after sampling in order to obtain reliable results. Experience has shown that freezing will degrade soft tissues. Long-term storage and samples for biological effects studies therefore require special conditions. Further advice on archiving and storage techniques used in maintaining biological tissues and other environmental samples for future contaminant analyses can be found in Technical Annexes 1 and 2 and in Tema Nord (1995). Details of the requirements for recording the storage and pre-treatment parameters are given in Technical Annexes 1 and 2.

6.1 Fish

43. If conditions allow, samples should be dissected immediately after collection; sub-samples of particular tissue should be removed and deep-frozen. Freezing undissected fish, particularly large ones, may cause soft tissues to degrade and may result in uncontrollable losses of the determinands in the tissue or cross-contamination from other deteriorating tissues. When there are no shipboard laboratories suitable for processing work, warranting the necessary precautionary conditions or personnel on board are not trained for such work, samples of ungutted fish should be preserved by deep freezing, preferably shock freezing to -20°C or lower as soon as practicable after collection. Sub-samples for enzymatic tests to be performed in parallel with contaminant analysis, must be stored in liquid nitrogen and analysed as soon as possible after the cruise. Only materials appropriate for the intended analytical techniques should be retained for storage (see Technical Annexes 1 and 2).

44. When pooling samples, an equivalent quantity of tissue must be taken from each fish, *e.g.* a whole fillet from every fish. If the total quantity of tissue obtained would be too large to be handled conveniently, the tissue may be sub-sampled, but a fixed proportion of each tissue must then be taken, *e.g.* 10% of the whole fish for muscle or 10% of each whole liver. This may cause an increase in the inter-individual variability, as contaminants are not equally distributed across the entire tissue. So the sub-sample should be taken from the same part of the organ/muscle of each individual.

6.2 Shellfish

45. Mussels should be depurated prior to preservation and analysis. This is to facilitate the discharge of unassimilated particles in the mantle cavity or the gut that might contaminate the sample. This is especially important for mussels collected in water with high turbidity or on silt/clay bottoms. Whether or not the sample has been depurated prior to storage and analysis should be reported. Mussels should be shucked while still alive and opened with minimum tissue damage. The soft tissue samples should be analysed immediately or stored at temperatures below -20°C.

6.3 Seabird eggs

46. To avoid deterioration, eggs should be frozen soon after collection and transported frozen to the laboratory. Details of the preparation of the eggs for subsequent chemical analysis are described in Technical Annexes 1 and 2.

7. Analytical procedures

47. Details of the requirements for recording the relevant parameters are given in Technical Annexes 1 and 2.

7.1 Organic contaminants

48. Procedures for the analysis of organic contaminants in biota include homogenisation, drying, extraction with organic solvents, removal of lipids, clean up, fractionation, followed by separation and detection of single compounds by means of gas chromatography with electron capture (GC-ECD) or mass-spectrometry (GC-MS, GC-MS^n) or lipid chromatography coupled with mass-spectrometry (LC-MS, LC-MS^n). The total fat weight should be determined, where sufficient material is available. The extractable lipid weight should also be determined on the extract used for organohalogen compound analyses. For tissue containing more than 10-15% of lipids, the results of both total fat and extractable lipid weight are comparable within acceptable limits. Particularly for small amounts of tissue available for analysis, sharing the sample for separate fat determination may result in an insufficient amount for the determination of the analytes and so should be avoided.

Results should be reported on a wet weight basis, along with the total fat and/or extractable lipid weight (in percentage). This will make it possible to recalculate values on both fat and lipid bases. Detailed information is given in Technical Annex 1.

7.2 Metals

49. Analysis of trace metals in biota generally includes homogenisation, drying, decomposition, dissolution, matrix separation and detection using element-specific spectrometric instrumental procedures (*e.g.* AAS, ICP-OES, ICP-MS, TXRF,). Recently developed spectrometric devices aim to reduce the often costly and time consuming sample preparation by applying direct methods without preceding matrix separation and decomposition steps. The results should be reported on a wet weight basis along with the dry weight percentage. Detailed information is given in Technical Annex 2.

8. Quality assurance

50. Quality assurance (QA) is the relevant part of the work related to all procedures from sampling to the final instrumental analytical measurement, within a quality management system required to ensure the consistent delivery of quality controlled information. All procedures must be evaluated and controlled on a regular basis. For this purpose a QA scheme must be established in each laboratory. This includes participation in inter laboratory proficiency testing schemes, preferably at an international level, to ensure the long-term stability of the laboratory's performance, the use of reference materials and the maintenance of all required documentation.

51. To minimise the risk of contamination or the loss of determinands during sampling, storage, pre-treatment or analysis (and so to avoid the generation of false data) QA measures should be applied to the sample from first contact to final measurement and data reporting. All detailed QA data should

be recorded in accordance with the QA procedures laid down in the relevant documents. Laboratories should work according to EN 17025.

9. Data reporting

52. Data reporting, including QA information, should be in accordance with the requirements set by the relevant OSPAR bodies to ensure that all information for the assessment procedure to be applied are available, and using the latest ICES reporting formats to ensure an efficient and controlled data storage and processing procedure. Information on the ICES data base is available via the ICES-Website (see references).

Monitoring Guidelines/Protocols for Sample Preparation and Analysis of Marine Biota for IMAP Common Indicator 17: Heavy and Trace Elements and Organic Contaminants

1. Introduction

1. Marine biota uptake contaminants from the marine environment through food and the water medium (breathing, skin exchange). Depending on their physicochemical properties and the organism's metabolism, contaminants may be bioaccumulated in the organism's body and, in some cases (such as Hg and persistent organic pollutants), they may be biomagnified in the top levels of the marine food chain. Since the establishment of the UNEP/MAP – MED POL Monitoring programme in 1981 (MED POL Phase II), the benthic fish *Mullus barbatus* and the bivalve *Mytilus galloprovincialis* have been used as sentinel species to assess the accumulation of contaminants in marine organisms of the Mediterranean Sea. In the framework of the Integrated Monitoring and Assessment Programme (IMAP) Common Indicator 17 (CI17), the same organisms are recommended for analysis, namely the benthic fish *Mullus barbatus* (muscle tissue) and the bivalves *Mytilus galloprovincialis* or *Donnax trunculus* (whole body). Parties may decide to include in their national monitoring programmes the collection and analysis of additional species of national interest. In all cases, contaminants data, along with relevant metadata, have to be reported to the UNEP/MAP Secretariat using the appropriate format.
2. Both organisms are encountered in the coastal marine environment and are absent in the offshore marine areas. Therefore, they cannot be used as sentinel organisms to assess the impact of contaminants in the offshore marine environment. For such offshore areas, appropriate sentinel species to be used for pollution assessment, will be designated by Parties at a later stage.
3. In line with IMAP requirements (UNEP 2019a[262], UNEP 2019b[263]), mandatory contaminants to be analysed in the muscle of fish and the whole body of bivalves include: heavy metals (Cadmium (Cd), Lead (Pb) and Mercury (Hg)), organochlorinated compounds (PCBs, hexachlorobenzene, lindane and ΣDDTs) and Polycyclic Aromatic Hydrocarbons (US EPA 16 Reference PAHs compounds). Also, additional parameters should be measured, such as: length, sex, and total wet weight of organism, as well as lipid content of the tissue to be analysed.
4. Heavy metals and organic contaminants are encountered in marine biota at trace levels (ng/kg - mg/kg); therefore, it is of paramount importance to avoid cross contamination from the laboratory environment (dust particles and the analyst), from sample containers or packing materials, from instruments used during sample pre-treatment and sample preparation, and from the chemical reagents used for analysis. Accordingly, sample handling and analysis should be made in a clean laboratory, to eliminate cross contamination and to control the total analytical blank. To that purpose, if the laboratory is not specifically designed as "clean lab" (class 100 US Federal Standard 209), it has to be equipped with appropriate laminar flow rooms, clean benches, and fume hoods, specifically designed for trace metal analysis.
5. The UNEP/MAP Proposed assessment criteria (Background Assessment Criteria - BAC and Environmental Assessment Criteria - EAC) for targeted heavy metals and organic contaminants in fish and bivalves are presented in the Annex XIV.
6. The Protocols on of this Guidelines, as provided here-below, aim at streamlining marine biota sample preparation and analysis for heavy metals and organic contaminants, including step-by-step guidance on the methods to be applied in the Mediterranean area for sample preparation and analysis of marine biota tissues for the determination of heavy metals and organic contaminants, in a view of assuring comparable quality assurance of the data, as well as comparability between sampling areas in different national monitoring programmes. They are not intended to be analytical training manuals, but guidelines for Mediterranean laboratories, which should be tested and modified in order to validate their final results.

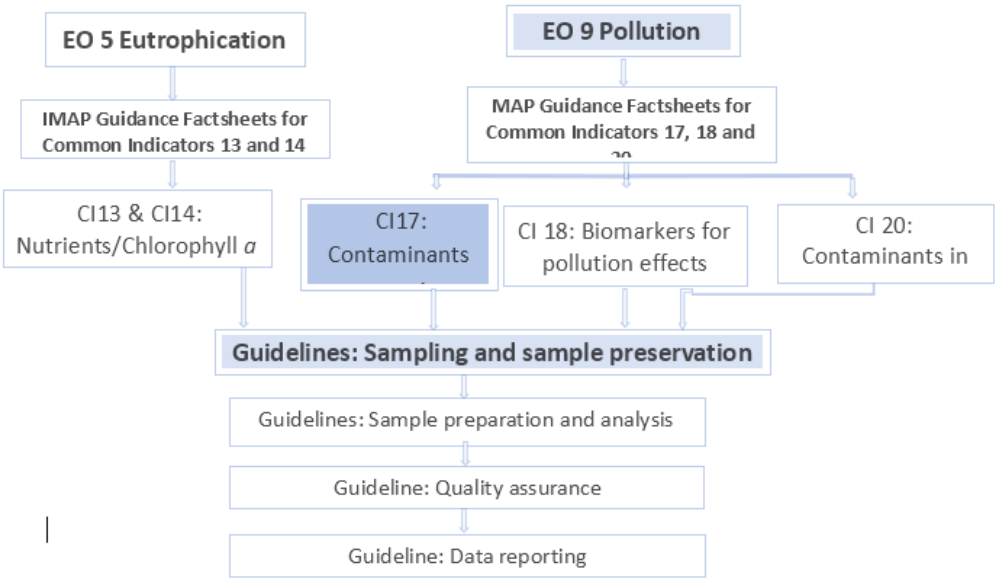
---

[262] (UNEP 2019a). UNEP/MED WG.467/5. IMAP Guidance Factsheets: Update for Common Indicators 13, 14, 17, 18, 20 and 21: New proposal for candidate indicators 26 and 27;;

[263] UNEP (2019b). UNEP/MED WG.463/6. Monitoring Protocols for IMAP Common Indicators related to pollution; UNEP/MAP (2019)

7. In order to avoid unnecessary repetitions, reference is also made to the protocols already published and publicly accessible, which can also be used by the Contracting Parties' competent laboratories participating in IMAP implementation. Namely, here-below elaborated IMAP Protocols build on previous UNEP/MAP - IAEA Recommended Methods, for the analysis of heavy metals and organic contaminants, such as: IAEA (2011a) IAEA (2011) Recommended method on microwave digestion of marine samples for the determination of trace element content (Annex I); IAEA (2011b) Recommended method for the determination of selected trace element in samples of marine origin by flame atomic absorption spectrometry (Annex III); IAEA (2011c) Recommended method for the determination of selected trace element in samples of marine origin by atomic absorption spectrometry using graphite furnace (Annex IV); IAEA (2012a) Recommended method on the determination of Total Mercury in marine samples by thermal decomposition, amalgamation and Atomic Absorption Spectrophotometry (Annex VI); IAEA (2012) Recommended method on the determination of Total Hg in samples or marine origin by Cold Vapour Atomic Absorption Spectrometry (Annex VII); UNEP/IAEA (2011d) Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment: Reference Methods for Marine Pollution Studies No 71 (Annex IX);, which were prepared in the framework of the MED POL monitoring programme. They are also streamlined with similar Guidelines/Protocols for marine biota sample preparation and analysis, which were developed by other Regional Seas Organisations, such as OSPAR (Annex XI and XIII) and HECLOM (Annexes II, VIII, X, XII). The analytical method developed by US EPA is also considered (Annex V). Given the suitability of any of these Guidelines in the context of IMAP, they can be further used by competent Mediterranean laboratories for developing their lab-specific sampling and sampling processing methodologies. The Parties' laboratories should accommodate and always test and modify each step of the procedures to validate their results.

8. The below flow diagram informs on the category of this Monitoring Guideline related to sample preparation and analysis of marine biota for IMAP Common Indicator 17 within the structure of all Monitoring Guidelines prepared for IMAP Common Indicators 13, 14, 17, 18 and 20.



Flow Diagram: Monitoring Guidelines for IMAP Ecological Objectives 5 and 9

2. Technical note for the analysis of biota samples for heavy metals

9. Analysis of marine biota samples for the determination of heavy metals include: i) digestion of biota tissues and ii) analysis of the digested sample for heavy metals.

10. National laboratories may decide to use any validated analytical method they consider appropriate, which meets specific performance criteria (LOD, LOQ, precision, recovery and specificity). However, in order to assist analytical laboratories of Mediterranean Parties, a non-exclusive list of Protocols has been drafted to be used as guidelines for the analysis of heavy metals in marine biota samples. Analytical laboratories should accommodate, test and modify each step of the procedures presented in the Protocols in order to validate their final results. The list of methods and analytical equipment is not exhaustive, and laboratories are encouraged to use their own equipment/methods that consider adequate for the required analyses.

11. Regardless of the analytical method used, heavy metal analysis follows some procedures common to all analytical methodologies, such as the calibration of the analytical equipment and the cleaning and handling procedures to avoid the contamination of the samples from the laboratory's environment and the tools and containers used in the analysis.

a) Calibration

12. Calibration standards prepared from single standard stock solutions or multielement standards, by dilution of the stock solution using dilute acid, as required. All standard solutions have to be stored in polyethylene, borosilicate or quartz volumetric flasks, depending on the best suitability for the respective analytes. Standard solutions with lower concentrations, if prepared correctly and controlled in a QA system (checking of old versus new, and checking with standards from a different source), can be kept for a period no longer than one month.

13. The calibration procedure has to meet some basic criteria in order to give the best estimate of the true element concentration of the sample analysed (HELCOM, 2012a[264]):

i) The concentrations of standards for the preparation of the calibration curve should cover the range of anticipated concentrations;
ii) The required analytical precision should be known and achievable throughout the entire range of concentrations;
iii) The measured value at the lower end of the range has to be significantly different from the procedural analytical blank;
iv) The chemical and physical properties of the calibration standards must closely resemble those of the sample under investigation;
v) The analytical instruments should be recalibrated regularly (every 10-20 samples) to correct for instrumental drift and analytical efficiency.

b) Avoiding contamination

14. To avoid metal contamination in the laboratory all glassware and plastic vessels used should be carefully cleaned. The general cleaning guidelines include:

i) The vessels are allowed to soak overnight in a plastic container in an alkaline surfactant solution (e.g. Micro solution 2% in tap or even better distilled water).
ii) Vessels are rinsed thoroughly first with tap or even better distilled water then with ultrapure deionised water (18 MΩ cm,).
iii) Vessels are left to stand in 10% (v/v) concentrated HNO_3 solution (analytical grade) at room temperature for at least 6 days.
iv) Vessels are thoroughly rinsed with ultrapure deionised water (at least 4 times).
v) Vessels are allowed to dry under a laminar flow hood.
vi) Vessels are stored in closed plastic polyethylene bags (e.g. zip-lock variety) to prevent the risk of contamination prior to use.

15. This procedure should be used for all plastic ware use in the laboratory as tips, cup for auto-sampler, plastic containers.

---

[264] HELCOM (2012a). Manual for marine monitoring in the COMBINE programme. Annex B-12, Appendix 4: Technical note on the determination of trace metallic elements in biota.

16. Under this Technical Note, this Guideline sfor sample preparation and analysis of marine biota for IMAP Common Indicator 17 provides the following IMAP Protocols for the analysis of heavy metals in marine biota samples:

- Protocol for biota tissues digestion using nitric acid (microwave assisted digestion in closed systems and digestion on hot plate);
- Protocol for the analysis of heavy metals with Flame Atomic Absorption Spectroscopy (F-AAS);
- Protocol for the analysis of heavy metals with Graphite Furnace Atomic Absorption Spectroscopy (GF-AAS);
- Protocol for the analysis of heavy metals with Inductive Coupled Plasma – Mass Spectroscopy (ICP-MS);
- Protocol for the analysis of Total Hg by thermal decomposition, amalgamation and Atomic Absorption Spectrophotometry;
- Protocol for the analysis of Total Hg with Cold Vapour Atomic Absorption Spectrometry (CV-AAS).

17. These Protocols are based on Analytical Methods developed by IAEA (Annex I: IAEA (2011a). IAEA (2011) Recommended method on microwave digestion of marine samples for the determination of trace element content; Annex III: IAEA (2011b) Recommended method for the determination of selected trace element in samples of marine origin by flame atomic absorption spectrometry; Annex IV: IAEA (2011c) Recommended method for the determination of selected trace element in samples of marine origin by atomic absorption spectrometry using graphite furnace; Annex VI: IAEA (2012a) Recommended method on the determination of Total Mercury in marine samples by thermal decomposition, amalgamation and Atomic Absorption Spectrophotometry (AAS); Annex VII: Recommended method on the determination of Total Hg in samples or marine origin by Cold Vapour Atomic Absorption Spectrometry), HELCOM (Annex II: Manual for marine monitoring in the COMBINE programme: Technical note on the determination of trace metallic elements in biota; Annex VIII: COMBINE Programme: Technical note on the determination of Total Mercury in marine biota by Cold Vapour Atomic Absorption Spectroscopy) and US EPA (Annex V: US-EPA Method 200.8: Determination of trace elements in waters and wastes by inductively coupled plasma-mass spectrometry).

2.1. Protocol for biota tissues digestion using nitric acid

18. Biota tissues samples have to be digested (wet ashing) prior to analysis. The rate of digestion and the efficiency of acid decomposition increase substantially with elevated temperatures and pressure, therefore microwave digestion in closed vessels is the preferred method. However, in case no such equipment is available, sample digestion in open vessels over a hot plate is an alternative method. Biota samples can be digested in wet or dried condition, however regardless of the method applied, it is of paramount importance to secure the complete destruction of all organic material of the sample, as well as to avoid metals losses and the contamination of the sample (HELCOM, 2012a).

19. The existence of residual dissolved organic carbon compounds in the digested sample would change the viscosity of the solution and therefore may lead to erroneous results when calibration of the AAS instrument is made using aquatic calibration standard solutions. Also, in the GF-AAS, residual organic carbon may undergo secondary reactions with the analyte prior to or during the atomization process causing matrix interferences (Harms, 1985[265]).

a) <u>Microwave acid digestion in closed systems (for heavy metals analysis with AAS, GFAAS and ICP-MS analysis)</u>

[265] Harms, U. 1985. Possibilities of improving the determination of extremely low lead concentrations in marine fish by graphite furnace atomic absorption spectrometry. Fresenius Journal of Analytical Chemistry, 322: 53-56.

20. Biota tissue digestion can be performed in Teflon, or equal quality vessels of pure material, which are metal free and resistant to strong acids, therefore loss of elements through volatilisation and contamination by desorption of impurities from the vessel surface are significantly reduced. Also, since only small quantities of high-purity nitric acid are used, extremely low analytical blanks can be obtained. Microwave systems enable a very fast energy transfer to the sample and a very rapid build-up of high internal vessel temperature and pressure, with the advantage of an enormous reduction in digestion time occurs (HELCOM, 2012a)

Digestion reagents for the analysis of Cd, Pb and other heavy metals analysis

21. The following reagents are required :
   i) HNO_3 (65%, e.g., Suprapur);
   ii) H_2O_2 (analytical grade) to be kept in the fridge after opening;
   iii) Ultrapure deionised water (> 18MΩ cm, e.g. Millipore).

22. Dried biota tissue samples (approximately 0.2. g) are weighted in the microwave vessel and placed in a laminar hood compatible with acid fume. Approximately 5 ml of nitric acid (HNO_3) are added and each vessel and left to react for at least 1hour (or more if possible). After the room temperature pre-digestion, 2ml of hydrogen peroxide (H_2O_2) are added carefully, the vessels are closed and placed in the microwave apparatus and digestion steps are followed. Detailed methods for biota tissues microwave digestion with strong acids are presented in Annex I ((IAEA 2011a[266])and Annex II (HELCOM 2012a).

23. All chemicals used in the analysis should be kept extremely clean once opened. Double bagged and only to be opened in a clean bench or clean room. It is also strongly advised not to use any pipettes or other devices to take out chemicals from the main container, but to subsample the chemicals into pre-cleaned containers for daily use. This is paramount to avoid contamination of the very expensive ultra clean chemicals needed for this analysis.

Digestion reagents for Mercury analysis

24. For Mercury analysis the following reagents are required:
i) HNO_3 (65%, analytical grade, certified low in mercury);
ii) Ultrapure deionised water (> 18MΩ cm,);
iii) 10% $K_2Cr_2O_7$ (w/v) solution (e.g. 10 g $K_2Cr_2O_7$ analytical grade diluted into 100 ml with ultrapure deionised water).
iv) V_2O_5 analytical grade

25. Dried biota tissue samples (approximately 0.2. to 1.5 g depending of the expected concentration) are weighted in the microwave vessel and placed in a laminar hood compatible with acid fume. If processing high weight of bivalve (> 1g), add 40 mg of V_2O_5 to each tube (including blanks). Five ml of concentrated nitric acid (HNO_3) are added and let to react for at least 1hour. If large amount of sample is used more acid should be added until the mixture becomes liquid. To control the performance of the digestion procedure, at least 2 blanks should be prepared in a similar manner as the samples for each batch of analysis. Also at least one Certified Reference Material should be used and prepared in duplicate for each digestion batch. These digestions are prepared in a similar manner as the samples. A reference material of similar composition and concentration range should be used. After digestion, the vessels are removed from the microwave apparatus and placed in a ventilated fume hood to cool. When the pressure is adequate, the vessels are opened 1 ml of $K_2Cr_2O_7$ solution is added (final concentration should be 2% v/v) and their content is transferred to a volumetric flask, preferably of Teflon, but glass is also good, and made to a known volume.

---

[266] IAEA (2011a). Recommended method on microwave digestion of marine samples for the determination of trace element content (IAEA/Marine Environmental Studies Laboratory in co-operation with UNEP/MAP MED POL)

b) Acid digestion in open systems

26. In case no microwave digestion system is available, it is possible to perform a digestion over a programmable heating plate placed inside a specially designed fume hood, allowing acid treatment. However, for the complete destruction of the organic matter, large quantities of reagents and voluminous apparatus with large surfaces are usually needed and the method is subject to contamination problems (too high blank values) if insufficiently purified acids are used. Also, the rate of reaction and efficiency of acid decomposition in open vessels is lower than in closed vessels under pressure. Therefore, digestion over a hot plate is not a recommended method and should be avoided if possible.

27. Dried biota tissue samples (approximately 0.2. g) are weighted in the microwave vessel and placed in a laminar flow hood compatible with acid fume. Approximately 5 ml of concentrated nitric acid (HNO_3) are added to each vessel and let to react at room temperature for at least 1 hour. The tubes are closed and placed in an aluminium block on a hot plate at 90°C for 3hrs. The samples are allowed to cool to room temperature, and the tubes are opened carefully, and the samples are transferred to the labelled 50 ml polypropylene graduated tubes or volumetric flasks.

28. A method for biota tissues digestion in open systems, using aqua regia, HNO_3 / $HClO_4$ can be found in Black et al, (2013[267]).

2.2. Protocol for the analysis of heavy metals with Flame AAS

29. Flame Atomic Absorption Spectroscopy (F-AAS) has adequate sensitivity for the determination of a wide range of metals in marine biota tissues. The sample solution is aspirated into a flame and atomized. In case of flame-AAS, a light beam is directed through the flame, into a monochromator, and onto a detector that measures the amount of light absorbed by the element in the flame. Each metal has its own characteristic wavelength, so a source hollow cathode lamp composed of that element is used. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

30. A detailed analytical protocol for the analysis of heavy metals in biota tissue samples prepared by IAEA (2011b[268]) is presented in the Annex III.

2.3. Protocol for the analysis of heavy metals with GF-AAS

31. In marine biota tissues Cd, Pb, as well as other heavy metals, can be determined by Graphite Furnace Atomic Absorption Spectroscopy (GF-AAS), which has adequate sensitivity for these determinations. For GF-AAS analysis, after the digestion of the biota sample, an aliquot of sample solution (10-50 µl) is introduced into a graphite tube of the GF-AAS and atomized by rapid heating at high temperature. A light beam is directed through the graphite tube, into a monochromator, and onto a detector that measures the amount of light absorbed by the atomized element in the tube. Each metal has its own characteristic wavelength, so a source hollow cathode lamp composed of that element is used. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

32. The AAS software generally gives typical electrothermal programs for each element for 10 µl of sample in diluted HNO_3 (0.1%) and indications concerning maximum ashing and atomization temperatures. More specific information may also be found in the literature, such as recommendations regarding matrix modifiers and the use of partition tubes or tubes with platform. When a program is optimized for the determination of an element in a specific matrix, all information should be reported in the logbook of methods of the laboratory.

---

[267] Black, K., Kalantzi, I., Karakassis, I., Papageorgiou, N., Pergantis, S., Shimmield, T. (2013). Heavy metals, trace elements and sediment geochemistry at four mediterranean fish farms, Science of the Total Environment. Elervier, 444, 128–137.

[268] IAEA (2011b) Recommended method for the determination of selected trace element in samples of marine origin by flame atomic absorption spectrometry

33. For some elements and some matrices, the results obtained are still not satisfactory (e.g. maximum ashing temperature is not sufficient to eliminate the background), this procedure should be redone with the addition of a matrix modifier. Different matrix modifiers could be tried before finding the best solution.
34. A detailed analytical protocol for the analysis of heavy metals in sediments by GF AAS prepared by IAEA (2011c[269]) is presented in the Annex IV.

2.4. Protocol for the analysis of heavy metals with ICP-MS

35. Inductive Coupled Plasma – Mass Spectroscopy (ICP-MS) is currently state-of-the-art instrumentation for metal analysis, with the possibility to determine at sub-µg L^{-1} concentrations of a large number of elements in acid digested biota tissue samples. ICP-MS allows a rapid analysis of a wide range of heavy metals. Most routine instruments utilize a quadrupole mass spectrometer, so mass resolution is not high enough to avoid overlap of double charged elements or multi-element ions (mainly hydrides, oxides and hydroxides) formed in the plasma. The main concern is for the Ar interferences as the plasma is usually an argon plasma, overlapping with As. Some elements are prone to memory effects (particularly Hg) and needs extra precautions to avoid carry over effects. Modern ICP-MS instruments software includes all the tuning and correction formulas needed and described above to perform the analysis (HELCOM 2012).
36. A multi-elemental determination of heavy metals by ICP-MS in water and solid samples after acid digestion, is described in the US EPA Method 200.8 (1994[270]). The method was initially intended for inorganic solid samples (soils and sediments) but can also be directly applied to organic samples. According to Enamorado-Baez et al. (2015[271]), for biota tissues the digestion step could use only nitric acid (similar to the US-EPA 3051 method established for sediments, sludge, soils, and oils) but increasing the sample mass to acid volume ratio.
37. Metal species originating in a liquid are nebulized and the resulting aerosol is transported by argon gas into the plasma torch. The ions produced by high temperatures are entrained in the plasma gas and introduced, by means of an interface, into a mass spectrometer. The ions produced in the plasma are sorted according to their mass-to-charge ratios and quantified with a channel electron multiplier. Interferences must be assessed, and valid corrections applied. Interference correction must include compensation for background ions contributed by the plasma gas, reagents, and constituents of the sample matrix. The US EPA Method 200.8 is presented in Annex V.

2.5. Protocol for the analysis of Total Mercury with by thermal decomposition, amalgamation and AAS

38. Total mercury in biological tissues can be analysed by solid Hg analyser, which has adequate sensitivity for this determination. A detailed method describing the protocol for the determination of total mercury (inorganic and organic) in sediment prepared by IAEA (2012a[272]) ("Recommended method on the determination of Total Mercury in marine samples by thermal decomposition, amalgamation and Atomic Absorption Spectrophotometry" Annex VI). With this method, Total Hg is determined without any chemical pre-treatment of the sample, minimising possible contamination

[269] IAEA (2011c) Recommended method for the determination of selected trace element in samples of marine origin by atomic absorption spectrometry using graphite furnace
[270] US EPA (1994) US-EPA Method 200.8: Determination of trace elements in waters and wastes by inductively coupled plasma-mass spectrometry.
[271] Enamorado-Báez, S.M., Abril, JM and Gómez-Guzmán, JM (2013) Determination of 25 Trace Element Concentrations in Biological Reference Materials by ICP-MS following Different Microwave-Assisted Acid Digestion Methods Based on Scaling Masses of Digested Samples. Hindawi Publishing Corporation, ISRN Analytical Chemistry, Volume 2013, Article ID 851713, 14 pages. http://dx.doi.org/10.1155/2013/851713
[272] IAEA (2012a) Recommended method on the determination of Total Hg in marine samples by Thermal Decomposition Amalgamation and Atomic Absorption Spectrometry

and/or additional errors due to sample handling. The method is based on the US EPA 7473 method (US EPA, 2007[273]).

39. The sample is dried and then chemically decomposed under oxygen in the decomposition furnace. The decomposition products are carried out to the catalytic section of the furnace, where oxidation is completed (halogens and nitrogen/sulfur oxides are trapped). The mercury present in the remaining decomposition products is selectively trapped on an amalgamator. After flushing the system with oxygen, the mercury vapour is released by rapid heating of the amalgamator, and carried through the absorbance cell in the light path of a single wavelength atomic absorption spectrophotometer. The absorbance is measured at 253.7 nm as a function of mercury quantity (ng). The typical working range is 0.1–500 ng. The mercury vapour is carried through a long (first) and a short path length absorbance cell. The same quantity of mercury is measured twice with different sensitivity resulting in a dynamic range that spans four orders of magnitude. The typical detection limit is 0.01 ng of mercury.

2.6. Protocol for the analysis of Total Hg in samples of marine origin by CV-AAS

40. The **Cold Vapour Atomic Absorption Spectrometry (**CV-AAS) method is widely used for the determination of total mercury in biological tissues and it is simple, rapid and applicable to a large number of environmental samples. The inorganic mercury is reduced to its elemental form with stannous chloride. The cold mercury vapour is then passed through the quartz absorption cell of an AAS instrument where its concentration is measured. The light beam of Hg hallow cathode lamp is directed through the quartz cell, into a monochromator and onto a detector that measures the amount of light absorbed by the atomized vapour in the cell. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

41. The typical working range is 0.25–100 ng mL^{-1} for direct injection of cold vapour, using "batch" system (IAEA, 2012b[274]). CV-AAS analysis can be performed manually using batch CV-AAS or automatically using flow injection (FIAS) techniques. FIAS is a very efficient approach for introducing and processing liquid samples in atomic absorption spectrometry, reduces sample and reagent consumption, and has a higher tolerance of interferences, lower determination limits and improved precision compared with conventional cold vapour techniques (HELCOM, 2012b[275]).

42. A recommended method describing the protocol for the determination of total mercury in biota prepared by IAEA (2012b) is presented in Annex VII. (Recommended method on the determination of Total Hg in samples or marine origin by Cold Vapour Atomic Absorption Spectrometry). A method for the determination of Total Hg in marine biota using CV-AAS is also proposed by HELCOM (2012b) (Annex VIII).

3. Technical note for the analysis of organic contaminants in marine biota

43. In line with IMAP requirements (UNEP/MAP, 2019; UNEP/MAP 2019a), the mandatory organic contaminants to be monitored in marine biota in the framework of the IMAP are: Organochlorinated compounds (PCBs [28, 31, 52, 101, 105, 118, 138, 153, 156, 180], Hexachlorobenzene, Lindane and ΣDDTs) and polycyclic aromatic hydrocarbons (US EPA 16 individual PAHs congeners – Acenaphene, Acenaphthylene, Anthracene, Benz(a)anthracene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Benzo(a)pyrene, Benzo(ghi)perylene, Chrysene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Naphthalene, Phenanthrene, Pyrene). However, Contracting Parties to the Barcelona Convention may decide to include in their national

[274] IAEA (2012b). Recommended method on the determination of Total Hg in samples or marine origin by Cold Vapour Atomic Absorption Spectrometry.

[275] HELCOM (2012b). COMBINE Annex B-12, Appendix 4, Attachment 1. Technical note on the determination of Total Mercury in marine biota by Cold Vapour Atomic Absorption Spectroscopy.

monitoring programmes the analysis of additional heavy organic compounds according to their national priorities.

44. Analysis of marine biota samples for the determination of organic contaminants include: i) extraction; ii) concentration; iii) clean-up; iv) fractionation; and v) quantification of contaminants.

45. National laboratories may decide to use any validated analytical method they consider appropriate, which meets specific performance criteria (LOD, LOQ, precision, recovery and specificity). However, in order to assist analytical laboratories of the Contracting Parties, the IMAP Protocols have been drafted to be used as guidelines for the analysis of organic compounds in marine biota samples. Analytical laboratories should accommodate, test and modify each step of the procedures presented in the IMAP Protocols in order to validate their final results. The list of methods and analytical equipment is not exhaustive, and laboratories are encouraged to use their own equipment/methods that consider adequate for the required analyses.

46. Under this Technical note, this Guideline sfor sample preparation and analysis of marine biota for IMAP Common Indicator 17 provides the following five IMAP Protocols:

- Protocol for the analysis of organochlorine pesticides and PCBs in biota using Gas Chromatography-Electron Capture Detector (GC-ECD);
- Protocol for the analysis of organochlorine pesticides and PCBs in biota using Gas Chromatography – Mass Spectrometry (GC-MS);
- Protocol for the analysis of PAHs in biota using High Performance Liquid Chromatography– Fluorescence (HPLC –UVF);
- Protocol for the analysis of PAHs in biota using Gas Chromatography – Mass Spectrometry GC-MS;
- Protocol for the normalization or organic contaminants concentrations using the lipid content **.**

47. These protocols are based on Analytical Methods developed by UNEP/IAEA (Annex IX: Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment. Reference Methods for Marine Pollution Studies No 71;), HELCOM (Annex X: Manual for marine monitoring COMBINE programme. Annex B-12, Appendix 3. Technical note on the determination of chlorinated biphenyls and organochlorine pesticides in biota; Annex XII: Manual for marine monitoring in the COMBINE programme. Annex B-12, Appendix 2. Technical Note on the determination of Polycyclic Aromatic Hydrocarbons in Biota) and ICES/OSPAR (Annex XI : CEMP Guidelines for monitoring contaminants in biota and sediments. Technical Annex 8: Determination of chlorobiphenyls in biota; Annex XIII: CEMP Guidelines for monitoring contaminants in biota and sediments. Technical Annex 3: Determination of parent and alkylated PAHs in biological materials).

3.1. Protocol for the analysis of organochlorine pesticides and PCBs in marine biota using GC-ECD

48. The analysis of PCBs and organochlorine pesticides (OCPs) in marine biota samples (fish muscle and bivalve whole body) involves extraction from the matrix with organic solvents, followed by clean-up and gas chromatographic separation with electron capture (GC-ECD) or mass spectrometric (GC-MS) detection. To minimize systematic errors due to insufficiently optimized gas chromatographic conditions, determinant losses (evaporation, unsatisfactory extraction yield), and/or contamination from laboratory ware, reagents and the laboratory environment, it is essential that the sources of systematic errors are identified and eliminated as far as possible (HELCOM, 2012c[276]).

49. For analysis, the samples are prepared for solvent extraction. To achieve a satisfactory recovery of the chlorinated hydrocarbons, samples are dried by either desiccation with anhydrous sodium sulphate or by freeze-drying. Lipids are then Soxhlet extracted from biota using hexane or petroleum ether. Following initial clean-up treatments (treatment of biota extracts with concentrated

[276] HELCOM (2012c). Manual for marine monitoring in the COMBINE programme. Annex B-12, Appendix 3. Technical note on the determination of chlorinated biphenyls and organochlorine pesticides in biota.

sulphuric acid to destroy some interfering lipids), extracts are fractionated using column chromatography.

50. All reagents, including the distilled water should be of analytical quality. Commercially available solvents like acetone, acetonitrile, dichloromethane, hexane and pentane are invariably contaminated with ECD-active substances; their concentrations vary from batch to batch and with supplier. Therefore, reagent quality should be checked by injection of 2 µl of a 100 ml batch of solvent, after concentration to 50 µl in a rotary evaporator. No peak in the GC-ECD chromatogram (90 - 250 °C) should be larger than that for 1pg of lindane. Otherwise, the solvent must be distilled.

51. The laboratory used for organic trace analysis must be a dedicated facility, isolated from other projects that could be sources of contamination. It must be properly constructed with fume hoods and benches with electric sockets that are safe for use with flammable solvents. The laboratory must have extractors and rotary evaporators cooling water to run the stills. In tropical regions and in dry climates, a refrigerated re-circulating system should be used to reduce temperatures to the required levels and/or to conserve water. Stainless steel or ceramic tiles make good non-contaminating surfaces. If necessary, benches can be coated with a hard epoxy resin and walls can be painted with epoxy paint. A sheet of aluminium foil on the workbench provides a surface which can be cleaned with solvent. A vented storage facility for solvents is essential. Benches must be fitted with frames to hold stills, extractors, etc. The emergency cut-off switch should be accessible from both inside and outside the laboratory. Firefighting equipment should be mounted in obvious places and laboratory personnel trained in their use.

52. Quantitative analysis with Electron Capture Detector (ECD) is performed by comparing the detector signal produced by the sample with that of defined standards. Due to incomplete separation, several co-eluting compounds can be present under a single detector signal, therefore, the shape and size of the signal have to be critically examined. The relative retention time and the signal size should be confirmed on columns with different polarity of their stationary phases, or by the use of multi-dimensional GC techniques. The GC should be calibrated before each batch of measurements. Since the ECD has a non-linear response curve, a multilevel calibration is strongly advised. For the purpose of determining recovery rates, an appropriate internal standard should be added to each sample at the beginning of the analytical procedure. The ideal internal standard is a PCB which is not present in the sample and which does not interfere with other PCBs (HELCOM, 2012c).

53. A step-by-step method for the determination of organochlorine pesticides and polychlorinated biphenyls in biological samples is prepared by UNEP/IAEA (2011d[277]) (Annex IX.), including the list of reagents, the solvents, standards and examples for the preparation of the stock, intermediate and working solutions. A method for the analysis of organochlorine pesticides and PCBs in biota tissues is also proposed by HELCOM (2012c) (Annex X) and OSPAR (2018a[278]) (Annex XI).

3.2. Protocol for the analysis of organochlorine pesticides and PCBs in marine biota using GC-MS

54. The analysis of PCBs and organochlorine pesticides (OCPs) in marine biota samples (fish muscle and bivalve whole body) involves extraction from the matrix with organic solvents, followed by clean-up and gas chromatographic separation with mass spectrometric (GC-MS) detection. For analysis, the samples are prepared for solvent extraction. To achieve a satisfactory recovery of the chlorinated hydrocarbons, samples are dried by either desiccation with anhydrous sodium sulphate or by freeze-drying. Lipids are then Soxhlet extracted from biota using hexane or petroleum ether. Following initial clean-up treatments (treatment of biota extracts with concentrated sulphuric acid to

[277] IAEA (2011d). Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment. Reference Methods for Marine Pollution Studies No 71

[278] ICES/OSPAR (2018a). CEMP Guidelines for monitoring contaminants in biota and sediments. Technical Annex 8. Determination of chlorobiphenyls in biota

destroy some interfering lipids), extracts are fractionated using column chromatography (UNEP/IAEA. 2011d).

55. Quantitative analysis is performed by comparing the detector signal produced by the sample with that of defined standards, using a mass spectrometer (MS). Often, due to incomplete separation, several co-eluting compounds can be present under a single detector signal. Therefore, the shape and size of the signal have to be critically examined. With a MS detector, either the molecular mass or characteristic mass fragments should be recorded for that purpose. The GC should be calibrated before each batch of measurements. Since the MS has a non-linear response curve, a multilevel calibration is advised. For the purpose of determining recovery rates, an appropriate internal standard should be added to each sample at the beginning of the analytical procedure..

56. A method for extraction, concentration, clean up and fractionation for the determination of organochlorine pesticides and polychlorinated biphenyls in biological samples is prepared by UNEP/IAEA (2011d) (Annex VIII.), including the list of reagents, the solvents, standards and examples for the preparation of the stock, intermediate and working solutions. The analysis of PCBs and organochlorinated pesticides can be done by GC-ECD followed by confirmation using GC-MS. A method for the analysis of organochlorine pesticides and PCBs in biota tissues using GC-MS is also proposed by HELCOM (2012c) (Annex X) and ICES/OSPAR (2018a) (Annex XI).

3.3. Protocol for the analysis of PAHs in marine biota using HPLC-Fluorescence

57. PAHs emitted from combustion processes are predominantly parent (un-substituted) compounds, while PAHs from petroleum and its by-products contain a range of alkylated compounds in addition to the parent PAHs. HPLC has the capacity to determine parent PAHs but has not the required selectivity to be used for alkylated PAHs' determination. However, this is not a handicap for the analysis of the EPA 16 PAHs, which are parent compounds.

58. PAHs are lipophilic and so are concentrated in the lipids of an organism, therefore they have to be extracted with Soxhlet extraction, or alkaline digestion followed by liquid-liquid extraction with an organic solvent. For Soxhlet extraction, wet tissues should be dried by mixing with a chemical agent (e.g., anhydrous sodium sulphate). Non-polar solvents alone will not effectively extract all the PAHs from tissues when using Soxhlet extraction, and mixtures such as hexane/dichloromethane may be effective. Tissue extracts will always contain many compounds other than PAHs, and a clean-up is necessary to remove those compounds which may interfere with the subsequent analysis. In order to reduce the sample volume to 2 cm^3 solvents are evaporated using a rotary-film evaporator at low temperature (water bath temperature of 30 °C or lower) and under controlled pressure conditions, in order to prevent losses of the more volatile PAHs such as naphthalenes. Evaporation to dryness should be avoided. When reducing the sample to final volume, solvents can be removed by a stream of clean nitrogen gas. Solvents and adsorptive materials must all be checked for the presence of PAHs and other interfering compounds. If such compounds are found, then the solvents, reagents, and adsorptive materials must be purified or cleaned using appropriate methods (HELCOM, 2012d[279]).

59. If Soxhlet extraction was used residual lipids have to be removed before the analytical determination, with an additional clean-up stage, using column chromatography with silica and alumina.

60. Detailed guidelines for the determination of Petroleum Hydrocarbons in biological samples using HPLC are prepared by HELCOM (2012d) (Annex XII) and ICES/OSPAR (2018b[280]) (Annex XIII).

[279] HELCOM (2012d). Manual for marine monitoring in the COMBINE programme. Annxe B-12, Appendix 2. Technical Note on the determination of Polycyclic Aromatic Hydrocarbons in Biota.

[280] ICES/OSPAR (2018b). CEMP Guidelines for monitoring contaminants in biota and sediments. Technical Annex 3. Determination of parent and alkylated PAHs in biological materials.

3.4. Protocol for the analysis of PAHs in marine biota using GC-MS

61. GC-MS analytical method has the sufficient selectivity to determine the full range of PAHs including parent (unsubstituted) PAH compounds (combustion derived) and alkylated PAH compounds (petroleum spill derived). (ICES/OSPAR, 2018).
62. Samples are Soxhlet extracted using methanol. Tissue extracts will always contain many compounds other than PAHs, and a clean-up is necessary to remove those compounds which may interfere with the subsequent analysis. In order to reduce the sample volume to 2 ml solvents are evaporated using a rotary-film evaporator at low temperature (water bath temperature of 30 °C or lower) and under controlled pressure conditions, in order to prevent losses of the more volatile PAHs such as naphthalenes. Evaporation to dryness should be avoided. When reducing the sample to final volume, solvents can be removed by a stream of clean nitrogen gas. Solvents and adsorptive materials must all be checked for the presence of PAHs and other interfering compounds. If such compounds are found, then the solvents, reagents, and adsorptive materials must be purified or cleaned using appropriate methods.
63. If Soxhlet extraction was used, residual lipids have to be removed before the analytical determination, with an additional clean-up stage, using column chromatography with silica and alumina.
64. Quantification is done by GC-MS. The two injection modes commonly used are splitless and on-column injection. Automatic sample injection should be used wherever possible to improve the reproducibility of injection and the precision of the overall method. If splitless injection is used, the liner should be of sufficient capacity to contain the injected solvent volume after evaporation. For PAH analysis, the cleanliness of the liner is also very important if adsorption effects and discrimination are to be avoided, and the analytical column should not contain active sites to which PAHs can be adsorbed. (HELCOM, 2012d).
65. Detailed methods for the determination of PAHs in biological samples using GC-MS are proposed by HELCOM (2012d) (Annex XII) and ICES/OSPAR (2018b) (Annex XIII).

3.5. Protocol for the normalization of organic contaminants concentrations using the lipid content

66. Normalisation to the total lipid content of marine biota is a means to reduce the variability of pollution level. For organic contaminants that accumulate through hydrophobic partitioning into the lipids of organisms, measured concentrations of contaminants in biota can be normalised to fish with a lipid content of 5% (European Commission 2014[281]). This default lipid content of 5% has been incorporated in the OECD (1996[282]) 305 Guideline for bioconcentration to ensure comparability between results of bioconcentration tests. The rationale behind this lipid normalisation is that the whole body biota concentration is linearly correlated with the lipid content of the species (EC 2014). Other taxonomic groups, such as bivalves, have different lipid contents than fish. For marine bivalves a lipid content of approximately 1% is proposed (European Food Safety Authority, 2009[283]).
67. There is evidence that using lipid contents for normalization purpose may not always be appropriate, because it requires a linear correlation between the concentration of contaminant and the lipid content, which may not be the case for PAHs (León et al., 2013[284]). Normalization can be useful

[281] European Commission (2014). Common implementation strategy for the Water Framework Directive (2000/60/EC). Guidance Document No. 32 on Biota Monitoring (the Implementation of EQSbiota) under the Water Framework Directive. Technical Report - 2014 – 083.
[282] OECD (1996). OECD Guidelines for Testing Chemicals: Proposal for Updating Guideline 305. Bioconcentration: Flow-Through Fish Test Paris 1996.
[283] EFSA. 2009 Guidance Document on Risk Assessment for Birds and Mammals. Parma, Italy: European Food Safety Authority. Authority EFS.358 pp.
[284] León V.M., Martínez-Gómez, C., García, I., Campillo, J.A, Benedicto J. (2013). Spatial distribution and temporal trends of polycyclic aromatic hydrocarbons in Mytilus galloprovincialis from the Iberian Mediterranean coast. Environmental Monitoring and Assessment, 185, 2, 1055-1070.

in specific areas with similar oceanographic conditions and/or for contaminants with a predominant diffuse input in the marine environment (such as PCBs), but not to compare areas subjected to different exposition to pollutants, food availability. Therefore, normalization to lipid content is not a mandatory parameter to be reported in the framework of IMAP, but is to the Contracting Parties to decide if such an exercise is useful in facilitating pollution detection in specific areas. However it is useful to include normalization procedures in the Guidelines, making clear that the method should be tested before being applied, using sufficient data from the area under investigation.

68. In case it is decided to apply normalise measured data to lipid content, a detailed procedure is described in the EC Guidance No 32 (EC 2014) (Annex XIV.). In such cases, European Commission's suggests that contaminant concentrations are normalised to lipid contents of 5% in fish and 1% in bivalves, or to dry weight contents of 26% in fish and 8.3% in bivalves, on the basis of the measured lipid content or dry weight, or on the basis of generic values for lipid content or dry weight for the relevant species obtained from FishBase Global Information System on Fish[285]

69. To calculate the normalised concentrations *concnorm, lipid* or *concnorm, dry weight* from measured concentrations *concmeas* for a fish species x, the following equations can be used (lipid content and dry weight content expressed as mass fractions):

$$concnorm,\ lipid = concmeas \cdot 0.05/lipid\ content_x$$

or

$$concnorm,\ dry\ weight = concmeas \cdot 0.26/dry\ weight_x$$

70. Similarly, to calculate the normalised concentrations *concnorm, lipid* or *concnorm, dry weight* from measured concentrations *concmeas* for a bivalve species x, the following equations can be used (lipid content and dry weight content expressed as mass fractions):

$$concnorm,\ lipid = concmeas \cdot 0.01/lipid\ content_x$$

or

$$concnorm,\ dry\ weight = concmeas \cdot 0.083/dry\ weight_x$$

71. It is also noted that using the exact lipid or dry weight content of the biota samples is always preferred over generic values for the species (such as those available from FishBase).

72. The total lipid content of fish or bivalves can be determined using the method of Bligh and Dyer (1959[286]) using chloroform/methanol extraction techniques (OECD, 1996) or, alternatively the method proposed by Smedes (1999[287]), which has a comparable efficiency of extraction and high accuracy, but is using less toxic organic solvents (propan-2-ol–cyclohexane–water (8 + 10 + 11 v/v/v) mixture to avoid the use of chloroform).

Recommended Method on
MICROWAVE DIGESTION OF MARINE SAMPLES
FOR THE DETERMINATION OF TRACE ELEMENT CONTENT

TABLE OF CONTENTS

NOTE: This method is not intended to be an analytical training manual. Therefore, the method is written with the assumption that it will be performed by formally trained analytical chemist. Several stages of this procedure are potentially hazardous, especially stages with HF; users should be familiar with the necessary safety precautions.

In addition, the IAEA's recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method, they shall not be used as absolute QC acceptance criteria.

1. SCOPE

The method here below describes the protocol for dissolution of samples from marine origin. Digests are suitable for analyses of total content of trace element in sediment and biological material.

The goal of this method is the total sample decomposition with the judicious choice of acid combinations this is achievable for most matrices. The selection of reagents which give the highest recoveries for the target analytes is considered the optimum method condition.

The recommended protocol is mainly based on the EPA 3052 method; users are encouraged to consult this document (EPA, 1996).

2. PRINCIPLE

The grinded and dried samples are solubilized in an acid mixture using microwave oven apparatus.

The use of hydrofluoric acid allows the decomposition of silicates by reaction of F with Si to form the volatile SiF4. The excess of hydrofluoric acid is either neutralized by boric acid, or digests are evaporated to dryness depending on the method used to analyze samples.

3. SAMPLE PRE-TREATMENT

Sediment samples are prepared following the recommendations of UNEP (2005).

Marine organisms are prepared following the recommendations of UNEP (1984, 1994).

4. REAGENTS

The reagents used shall meet the purity requirement of the subsequent analyses

4.1. ULTRAPUR WATER (type MilliQ).
4.2. NITRIC ACID 65%.
4.3. HYDROFLUORIC ACID.
4.4. HYDROCHLORIC ACID.
4.5. BORIC ACID.
4.6. HYDROGEN PEROXIDE.

5. MATERIAL

5.1. MICROWAVE APPARATUS

The microwave decomposition system should be temperature controlled. The temperature sensor should be accurate at ±2.5°C. The calibration of the temperature sensor should be done at least once a year, preferably by the maintenance service of the manufacturer.

The microwave unit should be corrosion resistant.

The unit cavity should be well ventilated and connected to fume cleaner or special neutralizing system.

The method requires microwave transparent and acid resistant material (i.e. PFA, TFM) to be used as reactor. The minimal volume of the vessels should be 45 ml and it should be able to work under the pressure of 800PSI. the reactor system should be equipped with a pressure relief system.

5.2. ANALYTICAL BALANCE with 0.001 g precision at least.
5.3. FUME HOOD.
5.4. LAMINAR FLOW HOOD.
5.5. VOLUMETRIC CONTAINERS of 50 ml or 100 ml in polypropylene.
5.6. WEIGHING CUP in polyethylene.
5.7. PLASTIC SPATULAS.

6. PROCEDURE

6.1. All PLASTIC MATERIAL (i.e. volumetric, weighing cup…) should be acid cleaned by soaking in laboratory soap (or 10% alcohol) for at least 24h, followed by 24h of soaking in 10% nitric acid. Stronger acid cleaning protocol could be applied depending on the requirement of the subsequent analyses.
6.2. MICROWAVE VESSELS should be at least cleaned after each use by running the same microwave program used for samples with 5 ml of HNO_3. If the risk of cross contamination is high (i.e. running sandy sediment after organic rich sediment) and/or in the case of long storage, the vessels should be cleaned twice. If available, an acid cleaner

(using acid vapors) can be used as a final cleaning stage. After cleaning, the vessels should be carefully rinsed with water and dried under a laminar flow hood. If a laminar flow hood is not available, vessels should be kept locked in double plastic bag; date of storage should be mentioned on the second bag.

6.3. Accurately weigh 0.1 to 0.5 g of well mixed sample in the microwave vessel.

6.4. In a fume hood, add 5 ml of nitric acid and 2 ml of hydrofluoric acid, close vessels with caps, then it is recommended to let samples react for at least 1 hour (or more if possible). Protect vessels by covering them with plastic bags or place them in a laminar flow hood compatible with acid fume. The quantity of hydrofluoric acid depends on the expected content of silicon dioxide, samples with low concentrations of silicon dioxide (< 10% like plant material to 0% like biological sample) may require less hydrofluoric acid (0.5 ml to 0 ml). Examples of acid quantities for different matrix are listed in table below.

	HF (ml)	HNO_3 (ml)	HCl (ml)	H_2O_2 (ml)	Boric (g)
Sediment	2	5	2 or 0	2	0.8
Fish	0	5	2 or 0	2	0
Sea plant	0.5	5	2 or 0	2	0

6.5. After room temperature pre-digestion, add 2 ml of hydrogen peroxide and close the reactors as recommended by the microwave manufacturer.

NOTE: The quantity and ratio of reagent can be adapted on a performance based judgment (i.e. visual total digestion, certified reference material results).

- In case of a sample containing high calcium carbonate, the hydrofluoric acid content can be set to 0 to avoid precipitation of insoluble CaF.
- A two stage digestion, using half of the hydrofluoric acid at the first stage and half at the second, could increase recovery and help achieving total decomposition.
- Additional reagent can be added depending on the sample composition to achieve complete dissolution. For example, 2±2 ml of HCl can be added to help the stabilization of As, Sb, Hg, Fe and Al at high level; however HCl might increase analytical difficulties for some techniques (i.e. ICP-MS) (Kingston 1997)
- Only one acid mixture or quantity should be used in a single batch, in the microwave, to insure consistent reaction conditions between all vessels and monitored conditions. This limitation is due to the current practice of monitoring a representative vessel, and applying a uniform microwave field to reproduce these reaction conditions within a group of vessels being simultaneously heated.

6.6. Place the closed reactor in the microwave apparatus, connect temperature and pressure control as specified by the manufacturer. The samples should be heated at 180°C

(minimum) in about 6 minutes and the temperature maintained for at least 10 minutes. The total decomposition is primarily controlled by maintaining samples at 180°C for 10 minutes. The ramping profile can be adapted, especially for safety purpose when very reactive samples are decomposed (i.e. biological material). In that case, it is recommended to increase the ramping time to 10 or 15 minutes. If possible, record temperature and pressure profile. In most samples matrices, pressure should peak between 5 and 15 minutes; profiles can be used to optimize temperature program.

6.7. At the end of the temperature profile, let the sample cool until the inside temperature goes down to 60°C, then remove the reactors from the microwave and place them in a ventilated fume hood. The pressure is carefully released following the manufacturer's instruction and reactors are opened.

6.8. In the case of removal of hydrofluoric acid excess with boric acid, 0.8 g of boric acid and 15 ml of water are added in the vessel. The quantity of boric acid is proportional to the quantity of hydrofluoric acid (usually 0.4 g for 1 ml should be sufficient). The vessels are closed again and run in the microwave with a program that heat samples at 170°C in 10 minutes and maintain this temperature for 10 minutes.

6.9. At the end of the temperature profile, let the sample cool until inside the temperature goes down to 60°C, then remove the reactors from the microwave and place them in a ventilated fume hood. The pressure is carefully released following the manufacturer's instruction and reactors are opened. Transfer the samples in a volumetric container and dilute them to a known volume (or a known weight, this requires to record the tare of each container before).

NOTE: An excess of boric acid will produce cloudy solutions, this might cause problem with sample introduction system of ICP. The use of boric acid will prevent measurement of boron, and possible bias introduced should be carefully investigated.

- If the use of boric acid is not possible, or if it is necessary to reduce the concentration of acid in final solutions, digest can be evaporated to incipient dryness on a hot plate at about 140°C. This stage should be performed in a controlled environment to avoid contamination and acid vapour should be treated. Some microwave oven apparatus can perform evaporation. The residue is then diluted to a known volume in nitric or hydrochloric diluted solution (usually 2% v/v) depending on the subsequent analytical method used.
- In case of insoluble precipitate or residue some extra steps can be performed like the addition of 2 ml of perchloric acid to the solution before evaporation, but this requires doing the evaporation under a specific hood for safety reason. Another option is the addition of 2 ml of concentrated hydrochloric acid, evaporation to near dryness, addition of concentrated nitric acid, evaporation to near dryness and dilution in known volume in 2% nitric acid solution.

Most samples will be totally dissolved by this method with the judicious choice of the acid combinations. A few refractory sample matrix compounds, such as TiO2, alumina, and other oxides may not be totally dissolved, and in some cases may sequester target analyte elements.

7. QUALITY CONTROL

7.1. Each microwave batch should contain at the minimum one certified reference material of representative matrix.

7.2. A duplicate or triplicate sample should be processed on a routine basis. A duplicate sample should be processed with each analytical batch or every 10 samples. A duplicate sample should be prepared for each matrix type (i.e. sediment, sea plant, etc.).

7.3. A spiked sample should also be included whenever a new sample matrix is being analyzed, especially if no certified reference material is available for that matrix.

7.4. Blank samples should be prepared using the same reagents and quantities used in sample preparation, placed in vessels of the same type, and processed with the samples. Each microwave batch should contain at least two blank samples.

HELCOM Manual for marine monitoring in the COMBINE programme

ANNEX B-12, APPENDIX 4: TECHNICAL NOTE ON THE DETERMINATION OF TRACE METALLIC ELEMENTS IN BIOTA

HELCOM Manual for marine monitoring in the COMBINE programme

ANNEX B-12, APPENDIX 4: TECHNICAL NOTE ON THE DETERMINATION OF TRACE METALLIC ELEMENTS IN BIOTA

1. INTRODUCTION

Metallic elements appear in different marine biological matrices in trace concentrations, ranging from the mg/kg through the ƒÊg/kg to the ng/kg level. Stoeppler (1991) provided a comprehensive review of the most frequently used techniques for quantitative analysis of metallic trace elements, such as optical atomic absorption, fluorescence or emission spectrometry, anodic, cathodic or adsorptive stripping voltammetry, isotope dilution mass spectrometry and total reflection X-ray fluorescence, respectively. In spite of the powerful instrumental techniques presently in use, various analytical error sources have to be taken into consideration that may significantly influence the accuracy of the analytical data.

2. WORKING CONDITIONS

For each step of the analytical procedure, contamination of the sample may occur from the environment (laboratory air dust particles and the analyst), from sample containers or packing materials, from instruments used during sample pre-treatment and sample preparation, and from the chemical reagents used for analysis. The predominant purpose of the analytical clean laboratory is to eliminate contamination, which may be airborne or laboratory-induced, as far as possible and to control the total analytical blank.
Contamination by particles from the laboratory air may be controlled by a high-efficiency particulate filter. (A clean room is designed to maintain air with 100 particles per ft3 or 3.6.103 per m3 of 0.5 ƒÊm particles (class 100 of U.S. Federal Standards 209), or better, preferably with a minimum of activity in the room.) U.S. Federal Standards 209 describes designs for complete laminar flow rooms, clean benches, and fume hoods, and contains information on design, testing, and maintenance of clean rooms, and should be considered an essential reference for those interested in a clean laboratory.
To control the analytical blank for analysis of metallic trace elements, one must not only maintain good laboratory air quality, but also select the appropriate composition and type of construction materials used to build the laboratory. Principally, contaminants must be effectively removed at the source to minimize their uncontrolled distribution in the analytical clean laboratory. Accordingly, the laboratory's walls should be cleaned easily and therefore painted with special metal-free wipe-resistant paints. Surfaces of working areas should be protected with, for example, disposable plastic (polyethylene, PTFE) foils. The floors should, for example, be covered with adhesive plastic mats. Details of the design that are essential for obtaining a working laboratory with low trace element blanks are described by Moody (1982), Mitchell (1982a), Boutron (1990), and Schmidt and Gerwinski (1994).

3. PREATREATMENT OF LABORATORY WARE AND REAGENTS, CONTAMINATION CONTROL

Chemically resistant materials, used in the production of high-quality laboratory ware appropriate for metallic trace element analysis, include low- and high-density polyethylene (LDPE and HDPE), polypropylene (PP), polytetrafluorethylene (PTFE), perfluoralkoxy (PFA), ethylenetetrafluorethylene (ETFE), tetrafluorethyleneper- fluorpropylene (FEP), borosilicate and quartz glass, respectively. With appropriate pretreatment and handling, these materials meet the requirements of purity necessary for the required analytical investigations. Cleaning procedures for plastic and glass laboratory ware were comprehensively dealt with by Moody and Lindstrom (1977), Tschopel et al. (1980), Kosta (1982) and Boutron (1990). Generally, immersion in diluted (10-25 % v/v) high-purity nitric acid at room temperature for a period of one to three days, followed by repeated rinsing with high-purity water, is recommended. Steaming in high-purity acids (predominantly nitric acid) is also very effective to remove impurities from container surfaces and condition them for subsequent analysis.

The materials mentioned above for the production of laboratory ware exhibit some adsorptive or exchange properties. Boundary-surface interactions can be important, particularly when very dilute analytical solutions are being handled, since uncontrollable losses through sorption of element ions can occur (Tschopel et al., 1980; Harms, 1985). Based on this information, it is imperative that volumetric flasks, reagent vessels, pipette tips, etc., for handling samples, sample solutions and low-level reference or analyte solutions must never be used for transferring or processing stock calibration solutions, analytes solutions or concentrated reagents. Considerable quantities of analytes may be adsorbed from such solutions by the respective container surfaces, residuals of which may be leached later when dilute sample or analyte solutions are handled.
The availability of high-purity reagents is a key condition for reliable investigations of metallic trace element concentrations. For many analytical problems, the level of a specific contaminant can adequately be controlled only by applying specific purification methods. The first order of priority in regard to high-purity reagents is a sufficient supply of high-purity water. Ion-exchange units are universally accepted as an effective means of removing dissolved ionic species from water. Since high-purity water is frequently used in metallic trace element analysis, equipment for sustainable production of high-purity water by high-purity mixed-bed ion exchange resins should be available. The next most important group of reagents are mineral acids. Contamination of the sample by residual concentrations of metallic trace elements in the acids used for dissolution or decomposition represents a major problem. Purification of the acids is essential to ensure acceptable blanks.
Isothermal (isopiestic) distillation can produce volatile acids (and ammonia) of medium concentration in high-purity form. For example, pure hydrochloric acid (and ammonia) can be generated by placing an open container of concentrated reagent-grade acid adjacent to a

container of high-purity water, within a closed system (such as a desiccator) at room temperature. Acid vapours are continuously transferred into the water until equilibrium is obtained. Purification by sub-boiling distillation is based on motionless evaporation of the liquid by infrared heating at the surface to prevent violent boiling. Different purification systems are described in detail by Matthinson (1972), Kuehner et al. (1972), Dabeka et al. (1976), Tschopel et al. (1980), Mitchell (1982b), Moody and Beary (1982), Moody et al. (1989), and Paulsen et al. (1989). Acids of extremely high purity are produced by multiple batchwise distillation of reagent-grade acids in a silica apparatus, which is placed in a laminar-flow hood.

4. SAMPLE PRETREATMENT

If the determinands are heterogeneously distributed in the sample material, it may be preferable to homogenize prior to taking subsamples for analysis. However, this procedural step is problematic, since uncontrollable contamination through the homogenizing tool may occur. Cryogenic homogenization at liquid nitrogen temperature and application of high-purity material such as quartz, PTFE, titanium or stainless steel for the construction of homogenizing devices may help to minimize contamination (Iyengar, 1976; Iyengar and Kasperek, 1977; Klussmann et al., 1985).

5. SAMPLE DECOMPOSITION

For accurate direct measurements of metallic trace element contents in biological matrices, appropriate calibration (reference) standards are lacking in most instances. Therefore, multi-stage, easy to calibrate methods are still necessary, which include decomposition procedures and transformation of biological material into solution.
As a general rule wet sample is to be subject to decomposition procedures to avoid contamination or loss of determinands. A general sample decomposition procedure cannot be recommended due to the diverse composition of materials to be analysed, as well as to the different elements to be determined, and also because of the variety of possible analytical methods applied. However, the following minimum requirements should be met:

- complete destruction of all organic material of the sample,
- avoidance of determinand losses,
- avoidance of contamination.

Complete decomposition of the organic matrix is a prerequisite for a variety of the subsequently used instrumental determination techniques. Residual dissolved organic carbon from biological materials incompletely disintegrated after decomposition with nitric acid causes problems particularly in voltammetric and polarographic determinations. Both are sensitive to interference from chelating and electroactive organic components coexisting in incompletely decomposed samples during analysis (Pratt et al., 1988; Wurfels

et al., 1987, 1989). Residual dissolved organic carbon compounds even of low molecular weight can change the equilibria in the spray chambers for sample introduction in atomic emission spectrometry (AES), optical emission spectrometry (OES), and atomic absorption spectrophotometry (AAS) by changing the viscosity of the sample solution. In such cases, comparison with pure aquatic calibration standard solutions can lead to erroneous results. In graphite furnace atomic absorption spectrophotometry (GFAAS), residual organic carbon may undergo complicated secondary reactions with the analyte prior to or during the atomization process. Such 'matrix interferences' alter the rate at which atoms enter the optical path relative to that obtained for an undisturbed element standard (Harms, 1985; and other references cited there).

The comparatively simple dry ashing method using a muffle furnace is problematic, since both uncontrollable losses of the determinands and contamination through contact with the furnace material may occur.

Both, application of a carefully developed and controlled temperature programme and modifying the matrix prior to the ashing procedure (addition of ashing aids agents) may be suitable to prevent losses of volatile elements (special analytical problems concerning mercury determination are described in Attachment 1). The use of special materials (quartz, titanium, stainless steel) for the construction of sample containers may be helpful to minimise contamination.

In the widely applied wet ashing procedure in open systems, the sample is treated with acids, mainly nitric, sulphuric and perchloric acids, in different ratios and under different conditions. Usually large quantities of reagents and voluminous apparatus with large surfaces are needed for complete destruction of the organic material. Serious contamination problems (too high blank values) may arise, if insufficiently purified acids are used.

The rate of reaction and efficiency of acid decomposition increase substantially with elevated temperatures. Accordingly, closed-vessel techniques, using conventional heating or microwave energy, have an advantage over open systems. As a result of the closed systems with vessels manufactured of dense and very pure material (PTFE, PFA, quartz), loss of elements through volatilisation and contamination by desorption of impurities from the vessel surface are significantly reduced. In addition, since only small quantities of high-purity acid (usually nitric acid) need to be used, extremely low analytical blanks can be obtained. Kingston and Jassie (1986, 1988) comprehensively considered the fundamental parameters governing closed vessel acid decomposition at elevated temperatures using a microwave radiation field. Microwave systems enable a very fast energy transfer to the sample and a very rapid build up of high internal vessel temperature and pressure, with the advantage of an enormous reduction in digestion time occurs. Furthermore, a reduction of acid volume

(McCarthy and Ellis, 1991) and contamination reduction during the decomposition process were found (Dunemann, 1994; Sheppard et al., 1994).

The application of microwave energy must be carefully controlled to avoid explosions; a pressure-relief system is recommended for safe operation (Gilman and Grooms, 1988). At this stage of development, it can be concluded that advances in pressure and temperature feedback control features have contributed to the acceptance of microwave sample decomposition in analytical chemistry.

6. CALIBRATION

For calibration purposes, single element standard stock solutions at a concentration of 1000 mg/l, purchased from a qualified manufacturer, should be available. The actual concentration of the named element should be stated on the label together with the date of the preparation of the standard solution.

Fresh stock standard solutions should be compared with the old standard solutions. Traceability can be ensured by the use of CRM(s) or participation in intercomparison exercises (EURACHEM, 2003).

Single or mixed element working standard solutions for calibration purposes are prepared by dilution of the standard stock solutions using dilute acid, as required.
Both stock standard and working standard solutions are stored in polyethylene, borosilicate or quartz volumetric flasks. Working standard solutions at concentrations less than 100 ƒÊg/l should be freshly prepared for every batch of samples and kept no longer than two weeks. The calibration procedure must meet some basic criteria in order to give the best estimate of the true (but unknown) element concentration of the sample analysed. These criteria are as follows:

- The amounts or concentrations of standards for the establishment of the calibration function must cover the range as related to practical conditions. The mean of the range should be roughly equal to the expected analyte concentration in the sample.
- The required analytical precision must be achievable and known throughout the entire range.
- The measured value (response) at the lower end of the range must be significantly different from the procedural analytical blank.
- The chemical and physical properties of the calibration standards must closely resemble those of the sample under investigation.
- The calibration standards must be processed through the entire analytical procedure in the same manner as the sample.

• The standard addition technique should be used only under very special circumstances (Cardone, 1986a, 1986b).

7. DETERMINATION

In an analytical series, especially with the number of samples >10, the control of calibration settings should be carried out with 2-3 calibration solution between environmental 10 samples. The analytical series should contain also a control sample of LRM or CRM.

Annex III:

Recommended method for the determination of selected trace element in samples of marine origin by flame atomic absorption spectrometry

Recommended method for the determination of selected trace element in samples of marine origin by flame atomic absorption spectrometry

Marine Environmental Studies Laboratory in co-operation with MED POL

November 2011

Table of Content

NOTE: This recommended method is not intended to be an analytical training manual. Therefore the method is written with the assumption that it will be performed by formally trained analytical chemists.

In addition the IAEA recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method they must not be used as absolute QC acceptance criteria,

The recommended protocol is mainly based on EPA 7000B method and ISO 11047 users are encouraged to consult this documents (US EPA, 2007; ISO 1998).

1. SCOPE:

This recommended method describes a protocol for measurement of Al, Ca, Co, Cr, Cu, Fe, Mg, Mn, Ni, Sr and Zn by flame (direct aspiration) atomic absorption spectrometry. The method is simple, rapid and applicable to a large number of environmental samples. This method is applicable when the element content in the digested solution is above the method limit. This limit will vary with the matrices and instrument model, indicative quantification limits are reported in table 1.

Table 1: Example of lower quantification limit for analyte in reagent water

Element	Lower quantification limit ($mg\ l^{-1}$)
Al	0.5
Ca	0.02
Co	0.06
Cr	0.1
Cu	0.04
Fe	0.05
Mg	0.003
Mn	0.03
Ni	0.07
Sr	0.06
Zn	0.01

2. PRINCIPLE:

The method is based on the atomic absorption spectrometric measurement of the element in the mineralised solutions. In direct-aspiration atomic absorption spectrophotometry, the solution is aspirated and atomized in a flame. A light beam from a hollow cathode lamp or an electrodeless discharge lamp is directed through the flame into a monochromator, and onto a detector that measures the amount of absorbed light. Absorption depends upon the presence of free unexcited ground-state atoms in the flame. Because the wavelength of the light beam is characteristic of only the metal being determined, the light energy absorbed by the flame is a measure of the concentration of that metal in the sample. This principle is the basis of atomic absorption spectrophotometry.

3. SAMPLE PRE-TREATMENT:

Samples are prepared following the recommended method for microwave digestion of marine samples for determination of trace element content. (IAEA recommended method, 2011).

4. REAGENT:

All reagent used should be free of contamination of analyte of interest

4.1. Water: Reagent water (referenced also as water in the text) should be free of contamination

4.2. Caesium chloride solution, 4g l^{-1}: Dissolve 4g of CsCl of at least 99.999% purity in reagent water to 1 liter.

4.3. Caesium-Lanthanum solution: weigh 5.865g of La_2O_3 and 12.67g of CsCl in 100ml container, add 50ml of reagent water and 25ml of HCl and dilute to 100ml. Commercial solution specially produced for AAS may be used.

4.4. Commercial standard solution 1000µg ml^{-1}: Use a certified reference material solution; this solution should be accompanied by a certificate that should include at the minimum the traceability of the certified concentration as well as the expiration date. The density of the solution or the certified content in mg kg^{-1} should also be defined to allow preparation of the calibration solution by weighing.

5. MATERIAL:

This section does not list common laboratory glassware

5.1. Atomic absorption spectrophotometer: This shall be equipped with: a hollow cathode lamp or an electrode-less discharge lamp appropriate to the element of interest (operated at the current recommended for the lamp by the instrument manufacturer), a background correction system, a burner suitable for an air/acetylene or nitrous oxide/acetylene flame (operated following the manufacturer's instructions). Deuterium background correction is the minimum technical specification acceptable for background correction for the measurement wavelengths below 350 nm.

5.2. Glassware: All glassware, polypropylene, or fluorocarbon (PFA or TFM) containers, including sample bottles, flasks and pipets tips, should be washed in the following sequence -- 24h soaking in laboratory soap (or 10% alcohol) followed by 24h soaking in 10% nitric acid, followed by 10% soaking in water, final rinse in water, drying under laminar flow hood. Cleaned items should be kept in double sealed plastic bags.

If it can be documented through an active analytical quality control program using spiked samples and method blanks that certain steps in the cleaning procedure are not needed for routine samples, those steps may be eliminated from the procedure (i.e. For the levels measured by flame AAS some sterile plastic containers are sufficiently free of contamination in certain analytes.)

5.3. Pipettes: microliter pipettes size ranging from 50 to 10000µl as needed. The accuracy and precision of the pipettes used should be checked as a routine every 6 months and obtained results should be compared with the individual certificates.

5.4. Volumetric containers preferably in polypropylene of a suitable precision and accuracy

6. INTERFERENCES:

6.1. The most troublesome type of interference in atomic absorption spectrometry is usually termed “chemical” and is cause by lack of absorption of atoms bound in molecular combination in the flame. This phenomenon can occur when the flame is not sufficiently hot to dissociate the molecule. The addition of chemical buffer (i.e. Lanthanum or calcium) or the use of nitrous oxide/acetylene gas mixture will help to prevent this interference.

6.2. The presence of high dissolved solids in the sample may result in interference from non-atomic absorbance such as light scattering. In the absence of background correction, this can result in false positive, signal contribution from uncorrected background which cannot be compensated by the method of standard addition.

6.3. Ionisation interference occurs when the flame temperature is sufficiently high to generate the removal of an electron from a neutral atom, giving a positively charged ion. This type of interference can generally be controlled by the addition of a large excess (~1mg l-1) of an easily ionized element such as K or Cs.

6.4. Spectral interference can occur when an absorbing wavelength of an element present in the sample, but not being determined, falls within the width of the absorption line of the element of interest. This type of interference may sometimes be reduced by narrowing the slid width.

Specific conditions applied to individual anaytes in case of known interferences are displayed in table 2.

Table 2: Instrument parameter

Element	Wavelength (nm)	Flame type	Chemical buffer*	Background	Typical calibration range (mg l^{-1})
Al	324.7	acetylene/NO2	Caesium chloride	Deuterium	1.5-40
Ca	422.7	acetylene/NO2	Caesium Lanthanum		0.02-1.2
Co	240.7	acetylene/air		Deuterium	0.06-4
Cr	357.9	acetylene/NO2			0.3-6
Cr	357.9	acetylene/air	Caesium chloride		0.1-6
Cu	324.7	acetylene/air		Deuterium	0.04-3
Fe	248.3	acetylene/air	Caesium chloride	Deuterium	0.05-3
Mg	285.2	acetylene/air	Caesium Lanthanum	Deuterium	0.003-0.3
Mn	279.5	acetylene/air	Caesium Lanthanum	Deuterium	0.03-3
Ni	232.0	acetylene/air		Deuterium	0.07-4
Sr		acetylene/NO2	Caesium chloride		0.06-5
Zn	213.9	acetylene/air		Deuterium	0.01-1.5

* see 4.2, 4.3and 7.4 for use of chemical buffer

7. PROCEDURE:

7.1.Sample solution: Use sample prepared following the recommended method for digestion of marine samples for the determination of trace metal (IAEA, 2011)

7.2.Blank solution: Prepare at least two blank solutions with each batch of sample using same procedure than for samples

7.3.Preparation of calibration solutions:

7.3.1. Before each batch of determination prepare by appropriate dilution of 1000µg ml^{-1} stock standard solution (4.4) at least 4 standard solutions and one calibration blank solution covering the appropriate range of the linear part of the curve. The calibration standards and calibration blank should be prepared using the same type of acid or combination of acids and at the same concentration as will result in the test portion.

7.3.2. Calibration solutions should be prepared fresh each day.

7.3.3. If necessary intermediate stock standard solutions can be prepared in 10% nitric acid, these solutions should be prepared monthly.

7.3.4. All volumetric material (pipettes and containers) should be of appropriate precision and accuracy, if not available standard solution can be prepared by weighing.

7.3.5. Example of calibration curve are given in table 2.

7.4. Special case: Use of chemical buffer. If a chemical buffer is added, it should be at the same concentration as in the sample solution (7.1), the blank (7.2), calibration blank and standard solutions (7.3) following the recommendation of table 2.

For CsCl add 5ml of 4g l^{-1} for 50 ml of solution (4.2)

For CsLa solution add 0.5ml for 50ml of solution (4.3)

The chemical buffer will be added to a separate portion of sample and blank solutions that will need to be diluted to a known volume.

7.5. Calibration

7.5.1. Set up the atomic absorption spectrometer according to the manufacturer's instructions at the appropriate wavelength using appropriate conditions (see table 2), and with the suitable background correction system in operation.

7.5.2. Aspirate a calibration solution (7.3) and optimize the aspiration conditions, burner height and flame conditions to get the maximum signal.

7.5.3. Adjust the response of the instrument to zero absorbance whilst aspirating water

7.5.4. Aspirate the set of calibration solutions in ascending order and, as a zero member, the blank calibration solution (7.3).

NOTE: Care should be taken to ensure that, when using the more concentrated standards, the absorbance is < 1, and preferably not more than 0,6.
The calibration curve is automatically plot from instrument software. The obtained curve should be linear with r<0.995.
To correct for the instrumental drift the calibration should be performed every 20 samples or if the calibration verification has failed (7.8.1).

7.6. Aspirate blank (7.2) and sample solutions (7.1) and record their concentrations calculated by software using the calibration curve.

7.7. If the concentration of the test portion exceeds the calibration range dilute the test portion with the blank solution accordingly.

As an option to avoid too big dilution factors and/or to avoid a diluting large number of solutions, if all solutions are exceeding the calibration range, the burner can be turned from 0 to 90° to decrease the instrument’s sensitivity. New calibration standard solutions should be prepared to match the sample range and the procedure should be repeated from (7.3).

7.8. Quality control solutions: Quality control solutions as describe below should be measured during the run.

7.8.1. **Initial Calibration Verification ICV**:

After initial calibration, the calibration curve must be verified by the use of initial calibration verification (ICV) standard.

The ICV standard is a standard solution made from an independent (second source) material at or near midrange. This solution as a calibration standard is prepared using the same type of acid or combination of acids and at the same concentration as will result in the test portion. If a chemical buffer is necessary it should be added in the ICV.

The acceptance criteria for the ICV standard must be ±10% of its true value

If the calibration curve cannot be verified within the specified limits, the cause must be determined and the instrument recalibrated before samples are analyzed. The analysis data for the ICV must be kept on file with the sample analysis

The calibration curve must also be verified at the end of each analysis batch and/or after every 10 samples. If the calibration cannot be verified within the specified limits, the sample analysis must be discontinued, the cause determined and the instrument recalibrated. All samples following the last acceptable test must be reanalyzed.

7.8.2. **Blank solution** (7.2): Maximum allowed blank concentration should be well documented and if blank solution exceeds this value all samples prepared along the contaminated blank should be prepared again and reanalysed.

7.8.3. **Post digestion spike**

Each unknown type of sample should be spike to check for potential matrix effect.

This spike is consider as a single point standard addition, and should be performed with a minimum dilution factor. The recovery of spike calculated as equation 1 should be 85-115%. If this test fails it is recommended to run analyses with standard addition method.

Spike solution: mix a fixe volume (V1) of sample solution, and a known volume (V2) of a standard solution of a known concentration (Cstandard)

Unspike solution: mix same fixe volume (V1) of sample solution, and same volume (V2) of reagent water

Measure concentration C (mg l^{-1}) in both solutions on the calibration curve (7.6), and calculate recovery as:

Equation 1 $$Cspike = \frac{Cstandard \times V2}{(V1+V2)}$$

Equation 2 $$R = \frac{C\ Spike\ Solution - C\ Unspike\ solution}{Cspike} \times 100$$

To be valid concentrations of spike and unspike solutions should be in the linearity range of the calibration curve and the Spike concentration (equation 1) should be in the range of 50-150% of the concentration of unspike solution.

7.8.4. **Dilution test**:

If the analyte concentration is sufficiently high (minimally, a factor of 10 above the lower limit of quantitation after dilution), an analysis of a 1:5

dilution should agree within ±10% of the original determination. If not, then a chemical or physical interference effect should be suspected, and method of standard addition is recommended.

7.8.5. **Certified Reference Material**:

At least one certified reference material of a representative matrix should be prepared with each batch of sample, the calculated result should fall in the value of the certificate within the coverage uncertainty.(Linsinger, 2010), to show evidence of unbiased result.

Results of CRM should be recorded for quality control purpose and plot in control chart (UNEP/IOC/IAEA 1994).

An example of sequence order with recommended criteria and actions is given in table 3.

8. CALCULATION OF RESULTS:

Results are calculated with equation 3

Equation 3: $w(m) = \frac{(\rho 1 - \rho 0)}{\mathrm{m}} \times f \times V \times R$

w(m) mass fraction of element m in the sample in mg kg^{-1}
ρ1: concentration of element m in milligrams per liter as measured in the sample solution
ρ0: concentration of element m in milligrams per liter as measured in the blank solution
f: is the dilution factor calculated as

$$f = \frac{final\ volume}{initial\ volume}$$

or equal to 1 if ρ1 is determined in undiluted solution
R: recovery calculated using CRM (see 7.8.5) or pre digestion spike

9. EXPRESSION OF RESULTS:

The rounding of values will depend of the uncertainty reported with the result; in general for this method no more than two significant figures will be reported.

Uncertainty component should be reported with all results. (ISO 2005, Nordtest 2004)

Example : w(Zn) = 8.5 ± 1.2 mg kg^{1}

Table 3: Example of an analytical sequence:

Solutions Description	Performance	Action
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1 -4	r>0.995	recalibrate in the linearity range
ICV	±10% of true value	Stop until resolve
Sample blank	< maximum allowed blank value	
CRM	Fall in certificate value within coverage uncertainty, or fall within acceptable criteria of the QC chart	Stop until resolve, check Matrix spike and run again with standard addition method if necessary
Matrix Spike	recovery 100% ± 15%	switch to standard addition, keep record for future analyses of the same matrix
Dilution Test	sample 1 = 5x sample 1 diluted 5x within 10%	switch to standard addition, keep record for future analyses of the same matrix
Unknown Sample 1-10	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute
ICV	±10% of true value	Stop until resolve
Unknown Sample 11-20	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1 -4	r>0.995	recalibrate in the linearity range
ICV	±10% of true value	Stop until resolve

Table of content

NOTE: This recommended method is not intended to be an analytical training manual. Therefore the method is written with the assumption that it will be performed by formally trained analytical chemist.
In addition, the IAEA recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method they must not be used as absolute QC acceptance criteria.

The recommended protocol is mainly based on EPA 7010 method and ISO 15586 users are encouraged to consult this documents (US EPA, 2007; ISO 2003)

1. SCOPE:

This International Standard includes principles and procedures for the determination of trace levels of: As, Cd, Co, Cr, Cu, Ni, Pb, and V in samples from marine origin, using atomic absorption spectrometry with electro thermal atomization in a graphite furnace. The method is applicable to the determination of low concentrations of elements. The detection limit of the method for each element depends on the sample matrix as well as the instrument, the type of atomizer and the use of chemical modifiers. Table 1 gives approximate working range and characteristic masses.

Table 1 Approximate characteristic masses and typical working range using 20µl sample volume

Element	Characteristic mass M_0* pg	Working range ng ml^{-1}
As	15	5-50
Cd	0.8	0.2-2
Co	10	3-30
Cr	3	2-20
Cu	10	3-30
Ni	13	5-50
Pb	15	5-50
V	35	10-100

**The characteristic mass (m_0) of an element is the mass in pg corresponding to a signal of 0.00044 unity using peak area as integration*

2. PRINCIPLE:

An aliquot of sample solution (5-50 µL) is introduced into a graphite tube of the GF AAS and atomized by rapid heating at high temperature. A light beam is directed through the graphite tube, into a monochromator, and onto a detector that measures the amount of light absorbed by the atomized element in the tube. Each metal has its own characteristic wavelength therefore a source hollow cathode lamp composed of that element is used. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

3. SAMPLE PRE-TREATMENT:

Samples are prepared following the recommended method for microwave digestion of marine samples for determination of trace element content. (IAEA recommended method, 2011)

4. REAGENTS:

4.1. Water: Reagent water (referenced also as water in the text) should be free of contamination

4.2. Concentrated acid solution as used for sample preparation (section 3)

4.3. Commercial standard solution 1000µg ml^{-1}: Use certified reference material solution; this solution should be accompanied by a certificate that should include at least the traceability of the certified concentration as well as the expiration date. The density of the solution or the certified content in mg kg-1 should also be defined to allow preparation of calibration solution by weighing.

4.4. Calibration solutions: Prepare calibration solutions from the standard solutions (4.3) by appropriate dilution. Intermediate standard solutions should be prepared in 2% (v/v) nitric acid. For calibration solution use the same amount of acid as that of the samples solutions.

Calibration solutions below 1 mg/l should not be used for more than one month, and those below 100 µg/l should not be used for more than one day.

4.5. Blank calibration solution: Prepare a blank calibration solution in the same way as the calibration solution but without adding standard. The final amount of acid will be the same as that of the sample solutions.

4.6. Palladium nitrate/magnesium nitrate modifier

Pd(NO3)2 solution is commercially available (10 g/l). Dissolve 0,259 g of Mg(NO3)2·6H2O in 100 ml of water. Mix the palladium nitrate solution with twice as much magnesium nitrate solution. 10 µl of the mixed solution is equal to 15 µg Pd and 10 µg Mg(NO3)2. The mixture is also commercially available.

Prepare a fresh solution monthly.

4.7. Magnesium nitrate modifier

Dissolve 0,865 g of Mg(NO3)2·6H2O in 100 ml of water. 10 µl of this solution is equal to 50 µg Mg(NO3)2.

4.8. Ammonium dihydrogen phosphate modifier

Dissolve 2,0 g of NH4H2PO4 in 100 ml of water. 10 µl of this solution is equal to 200 µg NH4H2PO4.

4.9. Ammonium dihydrogen phosphate/magnesium nitrate modifier

Dissolve 2,0 g of NH4H2PO4 and 0,173 g of Mg(NO3)2·6H2O in 100 ml of water. 10 µl of this solution is equal to 200 µg NH4H2PO4 and 10 µg Mg(NO3)2.

4.10. Palladium/Ammonium dihydrogen phosphate/magnesium nitrate modifier

Mix 2ml of Pd(NO3)2 solution is commercially available (10 g/l), 2ml of Mg(NO3)2 solution prepared as (4.7), 0.5ml of NH4H2PO4 prepared as (4.8) and dilute with water to 10ml. 4µl of this solution is equal to 8µg of Pd, 4µg of $Mg(NO_3)_2$ and 4µg of NH4H2PO4.

4.11. Nickel modifier

Dissolve 0,200 g of nickel powder in 1 ml concentrated nitric acid and dilute to 100 ml with water. 10 µl of this solution is equal to 20 µg Ni. Solutions of Ni(NO3)2 are also commercially available.

4.12. Iridium solution 1000µg ml^{-1}

Use commercial solution (standard)

4.13. Argon

5. MATERIALS:

5.1. Glassware: All glassware, polypropylene, or fluorocarbon (PFA or TFM) containers, including sample bottles, flasks and pipettes tips, should be washed in the following sequence -- 24h soaking in laboratory soap (or 10% alcohol) followed by 24h soaking in 10% nitric acid, followed by 10% soaking in water, final rinsing in water, drying under laminar flow hood. Cleaned items should be kept in double sealed plastic bags

5.2. Pipettes: microliter pipettes size ranging from 50 to 10000µl as needed. The accuracy and precision of the pipettes used should be checked as a routine every 6 months and the obtained results should be compared with the individual certificates.

5.3. Volumetric containers preferably in polypropylene of suitable precision and accuracy

5.4. Atomic Absorption Spectrometer equipped with graphite furnace, background correction system and necessary hallow cathode lamp.

5.5. Auto sampler

5.6. Polypropylene cups for automatic sampler cleaned as explained in (5.1)

5.7. Graphite tubes: pyrolytically-coated with platforms, preferably for highly and medium volatile elements, whereas elements of low volatility should be atomized from the wall. Provided satisfactory results are achieved, manufacturer's recommendations regarding the use of graphite tubes and platforms should be followed.

6. INTERFERENCES:

Some sample solutions, may contain large amounts of substances that may affect the results. High concentrations of chloride may cause low results, because the volatility of many elements is increased and analyte loss may occur during the pyrolysis step. Matrix effects may be overcome, partially or completely, by the optimization of the temperature program, the use of pyrolytically-coated tubes and platforms, the use of chemical modifiers, the standard addition technique and the use of background correction.

7. CHEMICAL MODIFICATION:

Chemical modifiers are used to overcome spectral and/or non-spectral interferences in a sample (matrix effects). In general, the aim of chemical modification is to allow a pyrolysis temperature that is high enough to remove the bulk of concomitants before the atomization step. In order to ascertain that the modification works, the spike procedures is performed with and without the addition of a chosen chemical modifier and recovery are compared

Spike experiment:

Spike solution: mix a fixe volume (V1) of sample solution, and a known volume (V2) of a standard solution of a known concentration (Cstandard)

Unspike solution: mix same fixe volume (V1) of sample solution, and same volume (V2) of reagent water

Measure concentration C (mg l^{-1}) in both solutions on the calibration curve, and calculate recovery as:

Equation 1 $$Cspike = \frac{Cstandard \times V2}{(V1+V2)}$$

Equation 2 $$R = \frac{C\ Spike\ Solution - C\ Unspike\ solution}{Cspike} \times 100$$

To be valid concentrations of spike and unspike solutions should be in the linearity range of the calibration curve and Spike concentration (equation 1) should be in the range of 50-150% of the concentration of unspike solution. The recovery should be 100 ± 15%

In Table 2 some recommendations of chemical modifiers are given.

Other chemical modifiers may be used if they show consistent results. Graphite tube can also be pretreated with Iridium (Vasileva 2001) as following:

Inject 50µl of the solution and run the temperature program below

Step	Temperature (°C)	Ramp Time (s)	Hold Time (s)
1	100	5	30
2	1200	20	5
3	100	5	2
4	2500	2	10

Repeat this 3 times, the coating is stable for about 200 injections and can be repeated

If chemical modifiers are used, add them to test samples, sample blank solutions, calibration solutions, and blank calibration solutions. Preferably inject the modifier solution with the auto sampler directly into the atomizer after the sample is delivered.

Table 2 Recommended chemical modifiers

Element	Chemical modifier	Amount* µg
As	Pd + $Mg(NO_3)_2$ or $NH_4H_2PO_4$	15+10 200
Cd	Pd + $Mg(NO_3)_2$+$NH_4H_2PO_4$ or Ir coating	8+4+4
Co	Pd + $Mg(NO_3)_2$	15+10
Cr	$Mg(NO_3)_2$	50
Cu	None	
Ni	$Mg(NO_3)_2$	50
Pb	Pd + $Mg(NO_3)_2$+$NH_4H_2PO_4$ or Ir coating	8+4+4
V	None	

**These amounts are only recommendation, significantly lower amounts may be required in some atomizers, see also recommendations from instrument manufacturers.*

8. PROCEDURE

8.1. Switch on the instrument and perform the optimization according to the manufacturer's instructions. Install an appropriate graphite tube, and set up the auto sampler.

8.2. Program the graphite furnace and the auto sampler. Examples of temperature program are given in table 3.

Note: Method for specific element and matrix should be developed and all necessary information should be stored with at least:

- *Temperature program*
- *Matrix modifier*
- *Type of graphite tube*
- *Matrix effect*
- *Type of calibration curve*
- *Typical m_0 obtained with the program*
- *Linearity*

Table 3 Example of temperature program

Element	Cu	Cu	Cd	Cd	Pb	Pb	As	As	Cr	Cr
Sample type	Sediment	Biota	Sediment	Biota	Sediment	Biota	Sediment	Biota	Sediment	Biota
Wavelengt(nm)	327.4	327.4	228.8	228.8	283.3	283.3	193.7	193.7	357.9	357.9
Graphite tube	Partition Tube	Partition Tube	platform	platform	platform	platform	platform	platform	Partition Tube	Partition Tube
Matrix Modifier	none	none	none	Pd,Mg, Amonium Phosphate	none	Pd,Mg ,Amonium Phosphate	Pd,Mg	Pd,Mg	none	none
Peak Measurement	area	area	area	area	area	area	area	area	area	area
M0(pg/0.0044 UA) on standard	13	13	1	1	16	16	15	15	2.5	2.5
Ashing T° (C°)	700	700	300	700	400	925	1400	1400	1100	1100
Atomisation T° (C°)	2300	2300	1800	1900	2100	2200	2600	2600	2600	2600
Remark							Number of Fire is critical	Standard Addition often required. Number of fire is critical	Use peak Height for lower concentration (peak shape)	Standard Addition often required. Use peak Height for lower concentration (peak shape)

8.3. Generality for measurements:

All measurements should be performed with at least duplicate injections of solutions; the relative standard deviation should be less than 5% for a signal above 0.01 unit of absorbance.

It is recommended to work in peak area.

Check the number of firing and change the graphite tube when appropriate, if graphite tube is changed during a run, the instrument needs to be recalibrated.

8.4. Run the calibration:

8.4.1. **Standard calibration technique**: Perform the calibration with a blank calibration solution (4.5) and 3 to 5 equidistant calibration solutions (4.4) for an appropriate concentration range.

To correct for the instrumental drift calibration should be performed every 10 samples (if possible the option of reslope using the middle standard point should be applied every 5 samples)

Calibration solutions can be prepared by the auto sampler from the highest standard solution, the minimum volume uptake should not be less than 4µl.

The blank calibration solution should be free of analyte, or below a well-documented maximum allowed calibration blank value (i.e. validation, control charts..).

It should be stressed that the linearity of the calibration curve is often limited. The calibration curve is automatically plot by instrument software, if linear regression is set checked that $r \leq 0.995$ or switch to second order equation.

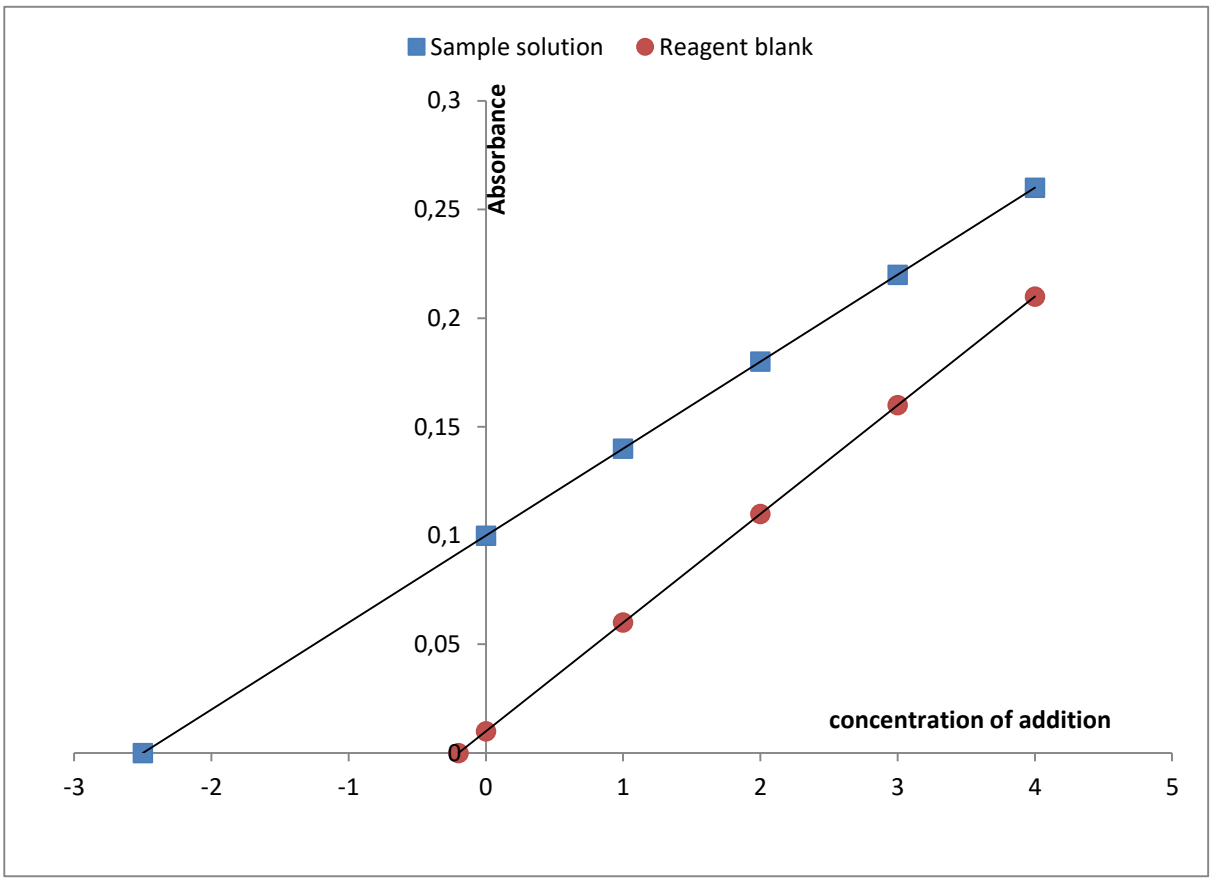
8.4.2. **Standard addition method**: This technique involves preparing same aliquots of sample solution with increasing amount of analyte. As describe in section 7 for the spike experiment using an increasing concentration of standard (V1 and V2 should stay the same). The auto sampler can be programed to perform standard addition. Determine the analyte concentration in the reagent blank solution the same way. Example of standard addition is given in figure 1. The concentration is obtained by dividing the absorbance of zero addition by the slope.

The standard addition should be performed for each type of matrix (i.e. a sediment sample solution cannot be measured with a standard addition curve done on a fish sample solution). For similar sample matrices (i.e. same fish species) the slope obtained with one sample can be used for other measurements respecting recalibration every 10samples.

For standard addition to be valid the following limitation should be taken into consideration:

- The resulting calibration should be linear ($r \leq 0.995$), software calibration equation is a linear regression
- The additions should represent ideally 50, 100, 150 and 200% of the sample concentration
- The standard addition technic cannot be used to correct for spectral interferences, such as unspecific background absorption, and should not be used if interferences change the signal by a factor of more than three.

Figure 1 Standard addition example



8.5. Measure sample blank and sample solutions (prepared following section 3) record the concentration as calculated by the software and calculate results following equation 3 (section 9), if samples exceed the highest point of calibration dilute appropriately. As an option a smaller volume of solution can be injected to stay under linear range of the instrument.

8.6. Quality control solutions: Quality control solutions as described below should be measured during the run. An example of a sequence order with recommended criteria and action is given in table 4.

Table 4 Example of analytical sequence:

Solutions Description	Performance	Action
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1 -4	r>0.995	recalibrate in the linearity range
ICV	±10% of true value	Stop until resolve
Sample blank	< maximum allowed blank value	
CRM	Fall in certificate value within coverage uncertainty, or fall within acceptable criteria of the QC chart	Stop until resolve, check Matrix spike and run again with standard addition method if necessary
Matrix Spike	recovery 100% ± 15%	switch to standard addition, keep record for future analyses of the same matrix
Dilution Test	sample 1 = 5x sample 1 diluted 5x within 10%	switch to standard addition, keep record for future analyses of the same matrix
Unknown Sample 1-10	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute

ETC…(restart sequence from calibration blank)

8.6.1. **Initial Calibration Verification ICV**:

After the initial calibration, the calibration curve must be verified using the initial calibration verification (ICV) standard.

The ICV standard is a standard solution made from an independent (second source) material at or near midrange. This solution as calibration standard is prepared using the same type of acid or combination of acids and at the same concentration as will result in the test portion.

The acceptance criteria for the ICV standard must be ±10% of its true value

If the calibration curve cannot be verified within the specified limits, the cause must be determined and the instrument recalibrated before samples are analyzed. The analysis data for the ICV must be kept on file with the sample analysis

The calibration curve must also be verified at the end of each analysis batch and/or after every 10 samples. If the calibration cannot be verified within the specified limits, the sample analysis must be discontinued, the cause determined and the instrument recalibrated. All samples following the last acceptable test must be reanalyzed.

8.6.2. **Blank solution** (4.5): Maximum allowed blank concentration should be well documented and if blank solution exceeds this value all samples prepared along the contaminated blank should be prepared again and re analyzed.

8.6.3. **Post digestion spike**

Each unknown type of sample should be spike to check for potential matrix effect.

This spike is consider as a single point standard addition, and should be performed with a minimum dilution factor. Recovery of spike calculated as equation 1 should be 85-115%. If this test failed it is recommended to run analyses with standard addition method. (see section 7 for detail)

8.6.4. **Dilution test**:

If the analyte concentration is sufficiently high (minimally, a factor of 10 above the lower limit of quantitation after dilution), an analysis of a 1:5 dilution should agree within ±10% of the original determination. If not, then a chemical or physical interference effect should be suspected, and method of standard addition is recommended.

8.6.5. **Certified reference material**:

At least one certified reference material of a representative matrix will be prepared with each batch of sample, the calculated result should be comparable with the value of the certificate within the coverage uncertainty.(Linsinger, 2010), to show evidence of unbias result.

Results of CRM should be record for quality control purpose and plot in control chart (UNEP/IOC/IAEA 1994)

9. CALCULATION OF RESULTS:

Results are calculated with equation 3

Equation 3: $w(m) = \frac{(\rho 1 - \rho 0)}{\mathrm{m}} \times f \times V \times R$

w(m) mass fraction of element m in the sample in mg kg^{-1}
ρ1: concentration of element m in milligrams per liter as measured in the sample solution
ρ0: concentration of element m in milligrams per liter as measured in the blank solution
f: is the dilution factor calculated as

$$f = \frac{final\ volume}{initial\ volume}$$

or equal to 1 if ρ1 is determined in undiluted solution
R: recovery calculated using CRM (see 8.6.5) or pre digestion spike

10. EXPRESSION OF RESULTS:

The rounding of values will depend of the uncertainty reported with the result. Uncertainty component should be reported with all results. (ISO 1995, Nordtest 2004)

Example : w(Pb) = 8.5 ± 1.2 mg kg^{1}

METHOD 200.8

DETERMINATION OF TRACE ELEMENTS IN WATERS AND WASTES BY INDUCTIVELY COUPLED PLASMA - MASS SPECTROMETRY

1.0 SCOPE AND APPLICATION

1.1 This method provides procedures for determination of dissolved elements in ground waters, surface waters and drinking water. It may also be used for determination of total recoverable element concentrations in these waters as well as wastewaters, sludges and soils samples. This method is applicable to the following elements:

Analyte		Chemical Abstract Services Registry Number (CASRN)
Aluminum	(Al)	7429-90-5
Antimony	(Sb)	7440-36-0
Arsenic	(As)	7440-38-2
Barium	(Ba)	7440-39-3
Beryllium	(Be)	7440-41-7
Cadmium	(Cd)	7440-43-9
Chromium	(Cr)	7440-47-3
Cobalt	(Co)	7440-48-4
Copper	(Cu)	7440-50-8
Lead	(Pb)	7439-92-1
Manganese	(Mn)	7439-96-5
Mercury	(Hg)	7439-97-6
Molybdenum	(Mo)	7439-98-7
Nickel	(Ni)	7440-02-0
Selenium	(Se)	7782-49-2
Silver	(Ag)	7440-22-4
Thallium	(Tl)	7440-28-0
Thorium	(Th)	7440-29-1
Uranium	(U)	7440-61-1
Vanadium	(V)	7440-62-2
Zinc	(Zn)	7440-66-6

Estimated instrument detection limits (IDLs) for these elements are listed in Table 1. These are intended as a guide to instrumental limits typical of a system optimized for multielement determinations and employing commercial instrumentation and pneumatic nebulization sample introduction. However, actual method detection limits (MDLs) and linear working ranges will be dependent on the sample matrix, instrumentation and selected operating conditions. Given in Table 7 are typical MDLs for both total recoverable determinations by "direct analysis" and where sample digestion is employed.

1.2 For reference where this method is approved for use in compliance monitoring programs [e.g., Clean Water Act (NPDES) or Safe Drinking Water Act (SDWA)] consult both the appropriate sections of the Code of Federal Regulation (40 CFR Part 136 Table 1B for NPDES, and Part 141 § 141.23 for drinking water), and the latest Federal Register announcements.

1.3 Dissolved elements are determined after suitable filtration and acid preservation. In order to reduce potential interferences, dissolved solids should not exceed 0.2% (w/v) (Section 4.1.4).

1.4 With the exception of silver, where this method is approved for the determination of certain metal and metalloid contaminants in drinking water, samples may be analyzed directly by pneumatic nebulization without acid digestion if the samples have been properly preserved with acid and have turbidity of <1 NTU at the time of analysis. This total recoverable determination procedure is referred to as "direct analysis".

1.5 For the determination of total recoverable analytes in aqueous and solid samples a digestion/extraction is required prior to analysis when the elements are not in solution (e.g., soils, sludges, sediments and aqueous samples that may contain particulate and suspended solids). Aqueous samples containing suspended or particulate material ≥1% (w/v) should be extracted as a solid type sample (Section 11.2.2).

1.6 The total recoverable sample digestion procedure given in this method is not suitable for the determination of volatile organo-mercury compounds. However, for "direct analysis" of drinking water (turbidity <1 NTU), the combined concentrations of inorganic and organo-mercury in solution can be determined by "direct analysis" pneumatic nebulization provided gold is added to both samples and standards alike to eliminate memory interference effects.

1.7 Silver is only slightly soluble in the presence of chloride unless there is a sufficient chloride concentration to form the soluble chloride complex. Therefore, low recoveries of silver may occur in samples, fortified sample matrices and even fortified blanks if determined as a dissolved analyte or by "direct analysis" where the sample has not been processed using the total recoverable mixed acid digestion. For this reason it is recommended that samples be digested prior to the determination of silver. The total recoverable sample digestion procedure given in this method is suitable for the determination of silver in aqueous samples containing concentrations up to 0.1 mg/L. For the analysis of wastewater samples containing higher concentrations of silver, succeeding smaller volume, well mixed sample aliquots must be prepared until the analysis solution contains <0.1 mg/L silver. The extraction of solid samples containing concentrations of silver >50 mg/kg should be treated in a similar manner.

1.8 The total recoverable sample digestion procedure given in this method will solubilize and hold in solution only minimal concentrations of barium in the presence of free sulfate. For the analysis of barium in samples having varying

and unknown concentrations of sulfate, analysis should be completed as soon as possible after sample preparation.

1.9 This method should be used by analysts experienced in the use of inductively coupled plasma mass spectrometry (ICP-MS), the interpretation of spectral and matrix interferences and procedures for their correction. A minimum of six months experience with commercial instrumentation is recommended.

1.10 Users of the method data should state the data-quality objectives prior to analysis. Users of the method must document and have on file the required initial demonstration performance data described in Section 9.2 prior to using the method for analysis.

2.0 SUMMARY OF METHOD

2.1 An aliquot of a well mixed, homogeneous aqueous or solid sample is accurately weighed or measured for sample processing. For total recoverable analysis of a solid or an aqueous sample containing undissolved material, analytes are first solubilized by gentle refluxing with nitric and hydrochloric acids. After cooling, the sample is made up to volume, is mixed and centrifuged or allowed to settle overnight prior to analysis. For the determination of dissolved analytes in a filtered aqueous sample aliquot, or for the "direct analysis" total recoverable determination of analytes in drinking water where sample turbidity is <1 NTU, the sample is made ready for analysis by the appropriate addition of nitric acid, and then diluted to a predetermined volume and mixed before analysis.

2.2 The method describes the multi-element determination of trace elements by ICP-MS.[1-3] Sample material in solution is introduced by pneumatic nebulization into a radiofrequency plasma where energy transfer processes cause desolvation, atomization and ionization. The ions are extracted from the plasma through a differentially pumped vacuum interface and separated on the basis of their mass-to-charge ratio by a quadrupole mass spectrometer having a minimum resolution capability of 1 amu peak width at 5% peak height. The ions transmitted through the quadrupole are detected by an electron multiplier or Faraday detector and the ion information processed by a data handling system. Interferences relating to the technique (Section 4.0) must be recognized and corrected for. Such corrections must include compensation for isobaric elemental interferences and interferences from polyatomic ions derived from the plasma gas, reagents or sample matrix. Instrumental drift as well as suppressions or enhancements of instrument response caused by the sample matrix must be corrected for by the use of internal standards.

3.0 DEFINITIONS

3.1 **Calibration Blank** - A volume of reagent water acidified with the same acid matrix as in the calibration standards. The calibration blank is a zero standard and is used to calibrate the ICP instrument (Section 7.6.1).

3.2 **Calibration Standard (CAL)** - A solution prepared from the dilution of stock standard solutions. The CAL solutions are used to calibrate the instrument response with respect to analyte concentration (Section 7.4).

3.3 **Dissolved Analyte** - The concentration of analyte in an aqueous sample that will pass through a 0.45 µm membrane filter assembly prior to sample acidification (Section 11.1).

3.4 **Field Reagent Blank (FRB)** - An aliquot of reagent water or other blank matrix that is placed in a sample container in the laboratory and treated as a sample in all respects, including shipment to the sampling site, exposure to the sampling site conditions, storage, preservation, and all analytical procedures. The purpose of the FRB is to determine if method analytes or other interferences are present in the field environment (Section 8.5).

3.5 **Instrument Detection Limit (IDL)** - The concentration equivalent to the analyte signal which is equal to three times the standard deviation of a series of 10 replicate measurements of the calibration blank signal at the selected analytical mass(es). (Table 1).

3.6 **Internal Standard** - Pure analyte(s) added to a sample, extract, or standard solution in known amount(s) and used to measure the relative responses of other method analytes that are components of the same sample or solution. The internal standard must be an analyte that is not a sample component (Sections 7.5 and 9.4.5).

3.7 **Laboratory Duplicates (LD1 and LD2)** - Two aliquots of the same sample taken in the laboratory and analyzed separately with identical procedures. Analyses of LD1 and LD2 indicates precision associated with laboratory procedures, but not with sample collection, preservation, or storage procedures.

3.8 **Laboratory Fortified Blank (LFB)** - An aliquot of LRB to which known quantities of the method analytes are added in the laboratory. The LFB is analyzed exactly like a sample, and its purpose is to determine whether the methodology is in control and whether the laboratory is capable of making accurate and precise measurements (Sections 7.9 and 9.3.2).

3.9 **Laboratory Fortified Sample Matrix (LFM)** - An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyzed exactly like a sample, and its purpose is to determine whether the sample matrix contributes bias to the analytical results. The background concentrations of the analytes in the sample matrix must be determined in a separate aliquot and the measured values in the LFM corrected for background concentrations (Section 9.4).

3.10 **Laboratory Reagent Blank (LRB)** - An aliquot of reagent water or other blank matrices that are treated exactly as a sample including exposure to all glassware, equipment, solvents, reagents, and internal standards that are used with other samples. The LRB is used to determine if method analytes or other interferences

are present in the laboratory environment, reagents, or apparatus (Sections 7.6.2 and 9.3.1).

3.11 **Linear Dynamic Range (LDR)** - The concentration range over which the instrument response to an analyte is linear (Section 9.2.2).

3.12 **Method Detection Limit (MDL)** - The minimum concentration of an analyte that can be identified, measured, and reported with 99% confidence that the analyte concentration is greater than zero (Section 9.2.4 and Table 7).

3.13 **Quality Control Sample (QCS)** - A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained from a source external to the laboratory and different from the source of calibration standards. It is used to check either laboratory or instrument performance (Sections 7.8 and 9.2.3).

3.14 **Solid Sample** - For the purpose of this method, a sample taken from material classified as either soil, sediment or sludge.

3.15 **Stock Standard Solution** - A concentrated solution containing one or more method analytes prepared in the laboratory using assayed reference materials or purchased from a reputable commercial source (Section 7.3).

3.16 **Total Recoverable Analyte** - The concentration of analyte determined either by "direct analysis" of an unfiltered acid preserved drinking water sample with turbidity of <1 NTU (Section 11.2.1), or by analysis of the solution extract of a solid sample or an unfiltered aqueous sample following digestion by refluxing with hot dilute mineral acid(s) as specified in the method (Sections 11.2 and 11.3).

3.17 **Tuning Solution** - A solution which is used to determine acceptable instrument performance prior to calibration and sample analyses (Section 7.7).

3.18 **Water Sample** - For the purpose of this method, a sample taken from one of the following sources: drinking, surface, ground, storm runoff, industrial or domestic wastewater.

4.0 INTERFERENCES

4.1 Several interference sources may cause inaccuracies in the determination of trace elements by ICP-MS. These are:

4.1.1 Isobaric elemental interferences - Are caused by isotopes of different elements which form singly or doubly charged ions of the same nominal mass-to-charge ratio and which cannot be resolved by the mass spectrometer in use. All elements determined by this method have, at a minimum, one isotope free of isobaric elemental interference. Of the analytical isotopes recommended for use with this method (Table 4), only molybdenum-98 (ruthenium) and selenium-82 (krypton) have isobaric elemental interferences. If alternative analytical isotopes having higher

natural abundance are selected in order to achieve greater sensitivity, an isobaric interference may occur. All data obtained under such conditions must be corrected by measuring the signal from another isotope of the interfering element and subtracting the appropriate signal ratio from the isotope of interest. A record of this correction process should be included with the report of the data. It should be noted that such corrections will only be as accurate as the accuracy of the isotope ratio used in the elemental equation for data calculations. Relevant isotope ratios should be established prior to the application of any corrections.

4.1.2 Abundance sensitivity - Is a property defining the degree to which the wings of a mass peak contribute to adjacent masses. The abundance sensitivity is affected by ion energy and quadrupole operating pressure. Wing overlap interferences may result when a small ion peak is being measured adjacent to a large one. The potential for these interferences should be recognized and the spectrometer resolution adjusted to minimize them.

4.1.3 Isobaric polyatomic ion interferences - Are caused by ions consisting of more than one atom which have the same nominal mass-to-charge ratio as the isotope of interest, and which cannot be resolved by the mass spectrometer in use. These ions are commonly formed in the plasma or interface system from support gases or sample components. Most of the common interferences have been identified[3], and these are listed in Table2 together with the method elements affected. Such interferences must be recognized, and when they cannot be avoided by the selection of alternative analytical isotopes, appropriate corrections must be made to the data. Equations for the correction of data should be established at the time of the analytical run sequence as the polyatomic ion interferences will be highly dependent on the sample matrix and chosen instrument conditions. In particular, the common ^{82}Kr interference that affects the determination of both arsenic and selenium, can be greatly reduced with the use of high purity krypton free argon.

4.1.4 Physical interferences - Are associated with the physical processes which govern the transport of sample into the plasma, sample conversion processes in the plasma, and the transmission of ions through the plasma-mass spectrometer interface. These interferences may result in differences between instrument responses for the sample and the calibration standards. Physical interferences may occur in the transfer of solution to the nebulizer (e.g., viscosity effects), at the point of aerosol formation and transport to the plasma (e.g., surface tension), or during excitation and ionization processes within the plasma itself. High levels of dissolved solids in the sample may contribute deposits of material on the extraction and/or skimmer cones reducing the effective diameter of the orifices and therefore ion transmission. Dissolved solids levels not exceeding 0.2% (w/v) have been recommended[3] to reduce such effects. Internal standardization may be effectively used to compensate for many physical interference effects.[4] Internal standards ideally should have similar

analytical behavior to the elements being determined.

4.1.5 Memory interferences - Result when isotopes of elements in a previous sample contribute to the signals measured in a new sample. Memory effects can result from sample deposition on the sampler and skimmer cones, and from the buildup of sample material in the plasma torch and spray chamber. The site where these effects occur is dependent on the element and can be minimized by flushing the system with a rinse blank between samples (Section 7.6.3). The possibility of memory interferences should be recognized within an analytical run and suitable rinse times should be used to reduce them. The rinse times necessary for a particular element should be estimated prior to analysis. This may be achieved by aspirating a standard containing elements corresponding to 10 times the upper end of the linear range for a normal sample analysis period, followed by analysis of the rinse blank at designated intervals. The length of time required to reduce analyte signals to within a factor of 10 of the method detection limit, should be noted. Memory interferences may also be assessed within an analytical run by using a minimum of three replicate integrations for data acquisition. If the integrated signal values drop consecutively, the analyst should be alerted to the possibility of a memory effect, and should examine the analyte concentration in the previous sample to identify if this was high. If a memory interference is suspected, the sample should be reanalyzed after a long rinse period. In the determination of mercury, which suffers from severe memory effects, the addition of 100 µg/L gold will effectively rinse 5 µg/L mercury in approximately two minutes. Higher concentrations will require a longer rinse time.

5.0 SAFETY

5.1 The toxicity or carcinogenicity of reagents used in this method have not been fully established. Each chemical should be regarded as a potential health hazard and exposure to these compounds should be as low as reasonably achievable. Each laboratory is responsible for maintaining a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this method.[5,8] A reference file of material data handling sheets should also be available to all personnel involved in the chemical analysis. Specifically, concentrated nitric and hydrochloric acids present various hazards and are moderately toxic and extremely irritating to skin and mucus membranes. Use these reagents in a fume hood whenever possible and if eye or skin contact occurs, flush with large volumes of water. Always wear safety glasses or a shield for eye protection, protective clothing and observe proper mixing when working with these reagents.

5.2 The acidification of samples containing reactive materials may result in the release of toxic gases, such as cyanides or sulfides. Acidification of samples should be done in a fume hood.

5.3 All personnel handling environmental samples known to contain or to have been

in contact with human waste should be immunized against known disease causative agents.

5.4 Analytical plasma sources emit radiofrequency radiation in addition to intense UV radiation. Suitable precautions should be taken to protect personnel from such hazards. The inductively coupled plasma should only be viewed with proper eye protection from UV emissions.

5.5 It is the responsibility of the user of this method to comply with relevant disposal and waste regulations. For guidance see Sections 14.0 and 15.0.

6.0 EQUIPMENT AND SUPPLIES

6.1 Inductively coupled plasma mass spectrometer:

6.1.1 Instrument capable of scanning the mass range 5-250 amu with a minimum resolution capability of 1 amu peak width at 5% peak height. Instrument may be fitted with a conventional or extended dynamic range detection system.

Note: If an electron multiplier detector is being used, precautions should be taken, where necessary, to prevent exposure to high ion flux. Otherwise changes in instrument response or damage to the multiplier may result.

6.1.2 Radio-frequency generator compliant with FCC regulations.

6.1.3 Argon gas supply - High purity grade (99.99%). When analyses are conducted frequently, liquid argon is more economical and requires less frequent replacement of tanks than compressed argon in conventional cylinders (Section 4.1.3).

6.1.4 A variable-speed peristaltic pump is required for solution delivery to the nebulizer.

6.1.5 A mass-flow controller on the nebulizer gas supply is required. A water-cooled spray chamber may be of benefit in reducing some types of interferences (e.g., from polyatomic oxide species).

6.1.6 If an electron multiplier detector is being used, precautions should be taken, where necessary, to prevent exposure to high ion flux. Otherwise changes in instrument response or damage to the multiplier may result. Samples having high concentrations of elements beyond the linear range of the instrument and with isotopes falling within scanning windows should be diluted prior to analysis.

6.2 Analytical balance, with capability to measure to 0.1 mg, for use in weighing solids, for preparing standards, and for determining dissolved solids in digests or extracts.

6.3 A temperature adjustable hot plate capable of maintaining a temperature of 95°C.

6.4 (Optional) A temperature adjustable block digester capable of maintaining a temperature of 95°C and equipped with 250 mL constricted digestion tubes.

6.5 (Optional) A steel cabinet centrifuge with guard bowl, electric timer and brake.

6.6 A gravity convection drying oven with thermostatic control capable of maintaining 105°C ± 5°C.

6.7 (Optional) An air displacement pipetter capable of delivering volumes ranging from 0.1-2500 µL with an assortment of high quality disposable pipet tips.

6.8 Mortar and pestle, ceramic or nonmetallic material.

6.9 Polypropylene sieve, 5-mesh (4 mm opening).

6.10 Labware - For determination of trace levels of elements, contamination and loss are of prime consideration. Potential contamination sources include improperly cleaned laboratory apparatus and general contamination within the laboratory environment from dust, etc. A clean laboratory work area designated for trace element sample handling must be used. Sample containers can introduce positive and negative errors in the determination of trace elements by (1) contributing contaminants through surface desorption or leaching, (2) depleting element concentrations through adsorption processes. All reusable labware (glass, quartz, polyethylene, PTFE, FEP, etc.) should be sufficiently clean for the task objectives. Several procedures found to provide clean labware include soaking overnight and thoroughly washing with laboratory-grade detergent and water, rinsing with tap water, and soaking for four hours or more in 20% (V/V) nitric acid or a mixture of dilute nitric and hydrochloric acid (1+2+9), followed by rinsing with reagent grade water and storing clean.

Note: Chromic acid must not be used for cleaning glassware.

6.10.1 Glassware - Volumetric flasks, graduated cylinders, funnels and centrifuge tubes (glass and/or metal free plastic).

6.10.2 Assorted calibrated pipettes.

6.10.3 Conical Phillips beakers (Corning 1080-250 or equivalent), 250 mL with 50 mm watch glasses.

6.10.4 Griffin beakers, 250 mL with 75 mm watch glasses and (optional) 75 mm ribbed watch glasses.

6.10.5 (Optional) PTFE and/or quartz beakers, 250 mL with PTFE covers.

6.10.6 Evaporating dishes or high-form crucibles, porcelain, 100 mL capacity.

6.10.7 Narrow-mouth storage bottles, FEP (fluorinated ethylene propylene) with ETFE (ethylene tetrafluorethylene) screw closure, 125-250 mL capacities.

6.10.8 One-piece stem FEP wash bottle with screw closure, 125 mL capacity.

7.0 REAGENTS AND STANDARDS

7.1 Reagents may contain elemental impurities that might affect the integrity of analytical data. Owing to the high sensitivity of ICP-MS, high-purity reagents should be used whenever possible. All acids used for this method must be of ultra high-purity grade. Suitable acids are available from a number of manufacturers or may be prepared by sub-boiling distillation. Nitric acid is preferred for ICP-MS in order to minimize polyatomic ion interferences. Several polyatomic ion interferences result when hydrochloric acid is used (Table 2), however, it should be noted that hydrochloric acid is required to maintain stability in solutions containing antimony and silver. When hydrochloric acid is used, corrections for the chloride polyatomic ion interferences must be applied to all data.

7.1.1 Nitric acid, concentrated (sp.gr. 1.41).

7.1.2 Nitric acid (1+1) - Add 500 mL conc. nitric acid to 400 mL of regent grade water and dilute to 1 L.

7.1.3 Nitric acid (1+9) - Add 100 mL conc. nitric acid to 400 mL of reagent grade water and dilute to 1 L.

7.1.4 Hydrochloric acid, concentrated (sp.gr. 1.19).

7.1.5 Hydrochloric acid (1+1) - Add 500 mL conc. hydrochloric acid to 400 mL of reagent grade water and dilute to 1 L.

7.1.6 Hydrochloric acid (1+4) - Add 200 mL conc. hydrochloric acid to 400 mL of reagent grade water and dilute to 1 L.

7.1.7 Ammonium hydroxide, concentrated (sp.gr. 0.902).

7.1.8 Tartaric acid (CASRN 87-69-4).

7.2 Reagent water - All references to reagent grade water in this method refer to ASTM Type I water (ASTM D1193).[9] Suitable water may be prepared by passing distilled water through a mixed bed of anion and cation exchange resins.

7.3 Standard Stock Solutions - Stock standards may be purchased from a reputable commercial source or prepared from ultra high-purity grade chemicals or metals (99.99-99.999% pure). All salts should be dried for one hour at 105°C, unless otherwise specified. Stock solutions should be stored in FEP bottles. Replace stock standards when succeeding dilutions for preparation of the multielement stock standards can not be verified.

CAUTION: Many metal salts are extremely toxic if inhaled or swallowed. Wash hands thoroughly after handling.

The following procedures may be used for preparing standard stock solutions:

Note: Some metals, particularly those which form surface oxides require cleaning prior to being weighed. This may be achieved by pickling the surface of the metal in acid. An amount in excess of the desired weight should be pickled repeatedly, rinsed with water, dried and weighed until the desired weight is achieved.

7.3.1 Aluminum solution, stock 1 mL = 1000 µg Al: Pickle aluminum metal in warm (1+1) HCl to an exact weight of 0.100 g. Dissolve in 10 mL conc. HCl and 2 mL conc. nitric acid, heating to effect solution. Continue heating until volume is reduced to 4 mL. Cool and add 4 mL reagent grade water. Heat until the volume is reduced to 2 mL. Cool and dilute to 100 mL with reagent grade water.

7.3.2 Antimony solution, stock 1 mL = 1000 µg Sb: Dissolve 0.100 g antimony powder in 2 mL (1+1) nitric acid and 0.5 mL conc. hydrochloric acid, heating to effect solution. Cool, add 20 mL reagent grade water and 0.15 g tartaric acid. Warm the solution to dissolve the white precipitate. Cool and dilute to 100 mL with reagent grade water.

7.3.3 Arsenic solution, stock 1 mL = 1000 µg As: Dissolve 0.1320 g As_2O_3 in a mixture of 50 mL reagent grade water and 1 mL conc. ammonium hydroxide. Heat gently to dissolve. Cool and acidify the solution with 2 mL conc. nitric acid. Dilute to 100 mL with reagent grade water.

7.3.4 Barium solution, stock 1 mL = 1000 µg Ba: Dissolve 0.1437 g $BaCO_3$ in a solution mixture of 10 mL reagent grade water and 2 mL conc. nitric acid. Heat and stir to effect solution and degassing. Dilute to 100 mL with reagent grade water.

7.3.5 Beryllium solution, stock 1 mL = 1000 µg Be: Dissolve 1.965 g $BeSO_4 \bullet 4H_2O$ (DO NOT DRY) in 50 mL reagent grade water. Add 1 mL conc. nitric acid. Dilute to 100 mL with reagent grade water.

7.3.6 Bismuth solution, stock 1 mL = 1000 µg Bi: Dissolve 0.1115 g Bi_2O_3 in 5 mL conc. nitric acid. Heat to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.7 Cadmium solution, stock 1 mL = 1000 µg Cd: Pickle cadmium metal in (1+9) nitric acid to an exact weight of 0.100 g. Dissolve in 5 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.8 Chromium solution, stock 1 mL = 1000 µg Cr: Dissolve 0.1923 g CrO_3 in a solution mixture of 10 mL reagent grade water and 1 mL conc. nitric

acid. Dilute to 100 mL with reagent grade water.

7.3.9 Cobalt solution, stock 1 mL = 1000 µg Co: Pickle cobalt metal in (1+9) nitric acid to an exact weight of 0.100 g. Dissolve in 5 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.10 Copper solution, stock 1 mL = 1000 µg Cu: Pickle copper metal in (1+9) nitric acid to an exact weight of 0.100 g. Dissolve in 5 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.11 Gold solution, stock 1 mL = 1000 µg Au: Dissolve 0.100 g high purity (99.9999%) Au shot in 10 mL of hot conc. nitric acid by dropwise addition of 5 mL conc. HCl and then reflux to expel oxides of nitrogen and chlorine. Cool and dilute to 100 mL with reagent grade water.

7.3.12 Indium solution, stock 1 mL = 1000 µg In: Pickle indium metal in (1+1) nitric acid to an exact weight of 0.100 g. Dissolve in 10 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.13 Lead solution, stock 1 mL = 1000 µg Pb: Dissolve 0.1599 g $PbNO_3$ in 5 mL (1+1) nitric acid. Dilute to 100 mL with reagent grade water.

7.3.14 Magnesium solution, stock 1 mL = 1000 µg Mg: Dissolve 0.1658 g MgO in 10 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.15 Manganese solution, stock 1 mL = 1000 µg Mn: Pickle manganese flake in (1+9) nitric acid to an exact weight of 0.100 g. Dissolve in 5 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.16 Mercury solution, stock, 1 mL = 1000 µg Hg: DO NOT DRY. **CAUTION**: highly toxic element. Dissolve 0.1354 g $HgCl_2$ in reagent water. Add 5.0 mL concentrated HNO_3 and dilute to 100 mL with reagent water.

7.3.17 Molybdenum solution, stock 1 mL = 1000 µg Mo: Dissolve 0.1500 g MoO_3 in a solution mixture of 10 mL reagent grade water and 1 mL conc. ammonium hydroxide., heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.18 Nickel solution, stock 1 mL = 1000 µg Ni: Dissolve 0.100 g nickel powder in 5 mL conc. nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.19 Scandium solution, stock 1 mL = 1000 µg Sc: Dissolve 0.1534 g Sc_2O_3 in 5 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to

100 mL with reagent grade water.

7.3.20 Selenium solution, stock 1 mL = 1000 µg Se: Dissolve 0.1405 g SeO_2 in 20 mL ASTM Type I water. Dilute to 100 mL with reagent grade water.

7.3.21 Silver solution, stock 1 mL = 1000 µg Ag: Dissolve 0.100 g silver metal in 5 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water. Store in dark container.

7.3.22 Terbium solution, stock 1 mL = 1000 µg Tb: Dissolve 0.1176 g Tb_4O_7 in 5 mL conc. nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.23 Thallium solution, stock 1 mL = 1000 µg Tl: Dissolve 0.1303 g $TlNO_3$ in a solution mixture of 10 mL reagent grade water and 1 mL conc. nitric acid. Dilute to 100 mL with reagent grade water.

7.3.24 Thorium solution, stock 1 mL = 1000 µg Th: Dissolve 0.2380 g $Th(NO_3)_4 \bullet 4H_2O$ (DO NOT DRY) in 20 mL reagent grade water. Dilute to 100 mL with reagent grade water.

7.3.25 Uranium solution, stock 1 mL = 1000 µg U: Dissolve 0.2110 g $UO_2(NO_3)_2 \bullet 6H_2O$ (DO NOT DRY) in 20 mL reagent grade water and dilute to 100 mL with reagent grade water.

7.3.26 Vanadium solution, stock 1 mL = 1000 µg V: Pickle vanadium metal in (1+9) nitric acid to an exact weight of 0.100 g. Dissolve in 5 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.27 Yttrium solution, stock 1 mL = 1000 µg Y: Dissolve 0.1270 g Y_2O_3 in 5 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.3.28 Zinc solution, stock 1 mL = 1000 µg Zn: Pickle zinc metal in (1+9) nitric acid to an exact weight of 0.100 g. Dissolve in 5 mL (1+1) nitric acid, heating to effect solution. Cool and dilute to 100 mL with reagent grade water.

7.4 Multielement Stock Standard Solutions - Care must be taken in the preparation of multielement stock standards that the elements are compatible and stable. Originating element stocks should be checked for the presence of impurities which might influence the accuracy of the standard. Freshly prepared standards should be transferred to acid cleaned, not previously used FEP fluorocarbon bottles for storage and monitored periodically for stability. The following combinations of elements are suggested:

Standard Solution A		Standard Solution B
Aluminum	Mercury	Barium
Antimony	Molybdenum	Silver
Arsenic	Nickel	
Beryllium	Selenium	
Cadmium	Thallium	
Chromium	Thorium	
Cobalt	Uranium	
Copper	Vanadium	
Lead	Zinc	
Manganese		

Except for selenium and mercury, multielement stock standard solutions A and B (1 mL = 10 µg) may be prepared by diluting 1.0 mL of each single element stock standard in the combination list to 100 mL with reagent water containing 1% (v/v) nitric acid. For mercury and selenium in solution A, aliquots of 0.05 mL and 5.0 mL of the respective stock standards should be diluted to the specified 100 mL (1 ml = 0.5 µg Hg and 50 µg Se). Replace the multielement stock standards when succeeding dilutions for preparation of the calibration standards cannot be verified with the quality control sample.

7.4.1 Preparation of calibration standards - fresh multielement calibration standards should be prepared every two weeks or as needed. Dilute each of the stock multielement standard solutions A and B to levels appropriate to the operating range of the instrument using reagent water containing 1% (v/v) nitric acid. The element concentrations in the standards should be sufficiently high to produce good measurement precision and to accurately define the slope of the response curve. Depending on the sensitivity of the instrument, concentrations ranging from 10-200 µg/L are suggested, except mercury, which should be limited to ≤5 µg/L. It should be noted the selenium concentration is always a factor of 5 greater than the other analytes. If the direct addition procedure is being used (Method A, Section 10.3), add internal standards (Section 7.5) to the calibration standards and store in FEP bottles. Calibration standards should be verified initially using a quality control sample (Section 7.8).

7.5 Internal Standards Stock Solution - 1 mL = 100 µg. Dilute 10 mL of scandium, yttrium, indium, terbium and bismuth stock standards (Section 7.3) to 100 mL with reagent water, and store in a FEP bottle. Use this solution concentrate for addition to blanks, calibration standards and samples, or dilute by an appropriate amount using 1% (v/v) nitric acid, if the internal standards are being added by peristaltic pump (Method B, Section 10.3).

Note: If mercury is to be determined by the "direct analysis" procedure, add an aliquot of the gold stock standard (Section 7.3.11) to the internal standard solution sufficient to provide a concentration of 100 µg/L in final the dilution of all blanks, calibration standards, and samples.

7.6 Blanks - Three types of blanks are required for this method. A calibration blank is used to establish the analytical calibration curve, the laboratory reagent blank is used to assess possible contamination from the sample preparation procedure and to assess spectral background and the rinse blank is used to flush the instrument between samples in order to reduce memory interferences.

7.6.1 Calibration blank - Consists of 1% (v/v) nitric acid in reagent grade water. If the direct addition procedure (Method A, Section 10.3) is being used, add internal standards.

7.6.2 Laboratory reagent blank (LRB) - Must contain all the reagents in the same volumes as used in processing the samples. The LRB must be carried through the same entire preparation scheme as the samples including digestion, when applicable. If the direct addition procedure (Method A, Section 10.3) is being used, add internal standards to the solution after preparation is complete.

7.6.3 Rinse blank - Consists of 2% (v/v) nitric acid in reagent grade water.

Note: If mercury is to be determined by the "direct analysis" procedure, add gold (Section 7.3.11) to the rinse blank to a concentration of 100 µg/L.

7.7 Tuning Solution - This solution is used for instrument tuning and mass calibration prior to analysis. The solution is prepared by mixing beryllium, magnesium, cobalt, indium and lead stock solutions (Section 7.3) in 1% (v/v) nitric acid to produce a concentration of 100 µg/L of each element. Internal standards are not added to this solution. (Depending on the sensitivity of the instrument, this solution may need to be diluted 10-fold.)

7.8 Quality Control Sample (QCS) - The QCS should be obtained from a source outside the laboratory. The concentration of the QCS solution analyzed will depend on the sensitivity of the instrument. To prepare the QCS dilute an appropriate aliquot of analytes to a concentration ≤100 µg/L in 1% (v/v) nitric acid. Because of lower sensitivity, selenium may be diluted to a concentration of <500 µg/L, however, in all cases, mercury should be limited to a concentration of ≤5 µg/L. If the direct addition procedure (Method A, Section 10.3) is being used, add internal standards after dilution, mix and store in a FEP bottle. The QCS should be analyzed as needed to meet data-quality needs and a fresh solution should be prepared quarterly or more frequently as needed.

7.9 Laboratory Fortified Blank (LFB) - To an aliquot of LRB, add aliquots from multielement stock standards A and B (Section 7.4) to prepared the LFB. Depending on the sensitivity of the instrument, the fortified concentration used should range from 40-100 µg/L for each analyte, except selenium and mercury. For selenium the concentration should range from 200-500 µg/L, while the concentration range mercury should be limited to 2-5 µg/L. The LFB must be carried through the same entire preparation scheme as the samples including sample digestion, when applicable. If the direct addition procedure (Method A, Section 10.3) is being used, add internal standards to this solution after

preparation has been completed.

8.0 SAMPLE COLLECTION, PRESERVATION, AND STORAGE

8.1 Prior to the collection of an aqueous sample, consideration should be given to the type of data required, (i.e., dissolved or total recoverable), so that appropriate preservation and pretreatment steps can be taken. The pH of all aqueous samples **must** be tested immediately prior to aliquoting for processing or "direct analysis" to ensure the sample has been properly preserved. If properly acid preserved, the sample can be held up to 6 months before analysis.

8.2 For the determination of dissolved elements, the sample must be filtered through a 0.45 µm pore diameter membrane filter at the time of collection or as soon thereafter as practically possible. Use a portion of the sample to rinse the filter flask, discard this portion and collect the required volume of filtrate. Acidify the filtrate with (1+1) nitric acid immediately following filtration to pH <2.

8.3 For the determination of total recoverable elements in aqueous samples, samples are **not** filtered, but acidified with (1+1) nitric acid to pH <2 (normally, 3 mL of (1+1) acid per liter of sample is sufficient for most ambient and drinking water samples). Preservation may be done at the time of collection, however, to avoid the hazards of strong acids in the field, transport restrictions, and possible contamination it is recommended that the samples be returned to the laboratory within two weeks of collection and acid preserved upon receipt in the laboratory. Following acidification, the sample should be mixed, held for 16 hours, and then verified to be pH <2 just prior withdrawing an aliquot for processing or "direct analysis". If for some reason such as high alkalinity the sample pH is verified to be >2, more acid must be added and the sample held for 16 hours until verified to be pH <2. See Section 8.1.

Note: When the nature of the sample is either unknown or known to be hazardous, acidification should be done in a fume hood. See Section 5.2.

8.4 Solid samples require no preservation prior to analysis other than storage at 4°C. There is no established holding time limitation for solid samples.

8.5 For aqueous samples, a field blank should be prepared and analyzed as required by the data user. Use the same container and acid as used in sample collection.

9.0 QUALITY CONTROL

9.1 Each laboratory using this method is required to operate a formal quality control (QC) program. The minimum requirements of this program consist of an initial demonstration of laboratory capability, and the periodic analysis of laboratory reagent blanks, fortified blanks and calibration solutions as a continuing check on performance. The laboratory is required to maintain performance records that define the quality of the data thus generated.

9.2 Initial Demonstration of Performance (mandatory)

9.2.1 The initial demonstration of performance is used to characterize instrument performance (determination of linear calibration ranges and analysis of quality control samples) and laboratory performance (determination of method detection limits) prior to analyses conducted by this method.

9.2.2 Linear calibration ranges - Linear calibration ranges are primarily detector limited. The upper limit of the linear calibration range should be established for each analyte by determining the signal responses from a minimum of three different concentration standards, one of which is close to the upper limit of the linear range. Care should be taken to avoid potential damage to the detector during this process. The linear calibration range which may be used for the analysis of samples should be judged by the analyst from the resulting data. The upper LDR limit should be an observed signal no more than 10% below the level extrapolated from lower standards. Determined sample analyte concentrations that are greater than 90% of the determined upper LDR limit must be diluted and reanalyzed. The LDRs should be verified whenever, in the judgement of the analyst, a change in analytical performance caused by either a change in instrument hardware or operating conditions would dictate they be redetermined.

9.2.3 Quality control sample (QCS) - When beginning the use of this method, on a quarterly basis or as required to meet data-quality needs, verify the calibration standards and acceptable instrument performance with the preparation and analyses of a QCS (Section 7.8). To verify the calibration standards the determined mean concentration from three analyses of the QCS must be within ±10% of the stated QCS value. If the QCS is used for determining acceptable on-going instrument performance, analysis of the QCS prepared to a concentration of 100 µg/L must be within ±10% of the stated value or within the acceptance limits listed in Table 8, whichever is the greater. (If the QCS is not within the required limits, an immediate second analysis of the QCS is recommended to confirm unacceptable performance.) If the calibration standards and/or acceptable instrument performance cannot be verified, the source of the problem must be identified and corrected before either proceeding on with the initial determination of method detection limits or continuing with on-going analyses.

9.2.4 Method detection limits (MDL) should be established for all analytes, using reagent water (blank) fortified at a concentration of two to five times the estimated detection limit.[7] To determine MDL values, take seven replicate aliquots of the fortified reagent water and process through the entire analytical method. Perform all calculations defined in the method and report the concentration values in the appropriate units. Calculate the MDL as follows:

$$MDL = (t) \times (S)$$

where:

t = Student's t value for a 99% confidence level and a standard deviation estimate with n-1 degrees of freedom [t = 3.14 for seven replicates]

S = standard deviation of the replicate analyses

Note: If additional confirmation is desired, reanalyze the seven replicate aliquots on two more nonconsecutive days and again calculate the MDL values for each day. An average of the three MDL values for each analyte may provide for a more appropriate MDL estimate. If the relative standard deviation (RSD) from the analyses of the seven aliquots is <10%, the concentration used to determine the analyte MDL may have been inappropriately high for the determination. If so, this could result in the calculation of an unrealistically low MDL. Concurrently, determination of MDL in reagent water represents a best case situation and does not reflect possible matrix effects of real world samples. However, successful analyses of LFMs (Section 9.4) can give confidence to the MDL value determined in reagent water. Typical single laboratory MDL values using this method are given in Table 7.

The MDLs must be sufficient to detect analytes at the required levels according to compliance monitoring regulation (Section 1.2). MDLs should be determined annually, when a new operator begins work or whenever, in the judgement of the analyst, a change in analytical performance caused by either a change in instrument hardware or operating conditions would dictate they be redetermined.

9.3 Assessing Laboratory Performance (mandatory)

9.3.1 Laboratory reagent blank (LRB) - The laboratory must analyze at least one LRB (Section 7.6.2) with each batch of 20 or fewer of samples of the same matrix. LRB data are used to assess contamination from the laboratory environment and to characterize spectral background from the reagents used in sample processing. LRB values that exceed the MDL indicate laboratory or reagent contamination should be suspected. When LRB values constitute 10% or more of the analyte level determined for a sample or is 2.2 times the analyte MDL whichever is greater, fresh aliquots of the samples must be prepared and analyzed again for the affected analytes after the source of contamination has been corrected and acceptable LRB values have been obtained.

9.3.2 Laboratory fortified blank (LFB) - The laboratory must analyze at least one LFB (Section 7.9) with each batch of samples. Calculate accuracy as percent recovery using the following equation:

$$R = \frac{LFB - LRB}{s} \times 100$$

where:

R = percent recovery
LFB = laboratory fortified blank
LRB = laboratory reagent blank
s = concentration equivalent of analyte added to fortify the LBR solution

If the recovery of any analyte falls outside the required control limits of 85-115%, that analyte is judged out of control, and the source of the problem should be identified and resolved before continuing analyses.

9.3.3 The laboratory must use LFB analyses data to assess laboratory performance against the required control limits of 85-115% (Section 9.3.2). When sufficient internal performance data become available (usually a minimum of 20-30 analyses), optional control limits can be developed from the mean percent recovery (x) and the standard deviation (S) of the mean percent recovery. These data can be used to establish the upper and lower control limits as follows:

UPPER CONTROL LIMIT = x + 3S
LOWER CONTROL LIMIT = x - 3S

The optional control limits must be equal to or better than the required control limits of 85-115%. After each five to ten new recovery measurements, new control limits can be calculated using only the most recent 20-30 data points. Also, the standard deviation (S) data should be used to establish an on-going precision statement for the level of concentrations included in the LFB. These data must be kept on file and be available for review.

9.3.4 Instrument performance - For all determinations the laboratory must check instrument performance and verify that the instrument is properly calibrated on a continuing basis. To verify calibration run the calibration blank and calibration standards as surrogate samples immediately following each calibration routine, after every ten analyses and at the end of the sample run. The results of the analyses of the standards will indicate whether the calibration remains valid. The analysis of all analytes within the standard solutions must be within ±10% of calibration. If the calibration cannot be verified within the specified limits, the instrument must be recalibrated. (The instrument responses from the calibration check may be used for recalibration purposes, however, it must be verified before continuing sample analysis.) If the continuing calibration check is not confirmed within ±15%, the previous 10 samples must be reanalyzed after recalibration. If the sample matrix is responsible for the calibration drift, it is recommended that the previous 10 samples are reanalyzed in groups of five between calibration checks to prevent a similar drift situation from occurring.

9.4 Assessing Analyte Recovery and Data Quality

9.4.1 Sample homogeneity and the chemical nature of the sample matrix can affect analyte recovery and the quality of the data. Taking separate aliquots from the sample for replicate and fortified analyses can in some cases assess the effect. Unless otherwise specified by the data user, laboratory or program, the following laboratory fortified matrix (LFM) procedure (Section 9.4.2) is required.

9.4.2 The laboratory must add a known amount of analyte to a minimum of 10% of the routine samples. In each case the LFM aliquot must be a duplicate of the aliquot used for sample analysis and for total recoverable determinations added prior to sample preparation. For water samples, the added analyte concentration must be the same as that used in the laboratory fortified blank (Section 7.9). For solid samples, the concentration added should be 100 mg/kg equivalent (200 µg/L in the analysis solution) except silver which should be limited to 50 mg/kg (Section 1.8). Over time, samples from all routine sample sources should be fortified.

9.4.3 Calculate the percent recovery for each analyte, corrected for background concentrations measured in the unfortified sample, and compare these values to the designated LFM recovery range of 70-130%. Recovery calculations are not required if the concentration of the analyte added is less than 30% of the sample background concentration. Percent recovery may be calculated in units appropriate to the matrix, using the following equation:

$$R = \frac{C_s - C}{s} \times 100$$

where:

R = percent recovery
C_s = fortified sample concentration
C = sample background concentration
s = concentration equivalent of analyte added to fortify the sample

9.4.4 If recovery of any analyte falls outside the designated range and laboratory performance for that analyte is shown to be in control (Section 9.3), the recovery problem encountered with the fortified sample is judged to be matrix related, not system related. The data user should be informed that the result for that analyte in the unfortified sample is suspect due to either the heterogeneous nature of the sample or an uncorrected matrix effect.

9.4.5 Internal standards responses - The analyst is expected to monitor the responses from the internal standards throughout the sample set being

analyzed. Ratios of the internal standards responses against each other should also be monitored routinely. This information may be used to detect potential problems caused by mass dependent drift, errors incurred in adding the internal standards or increases in the concentrations of individual internal standards caused by background contributions from the sample. The absolute response of any one internal standard must not deviate more than 60-125% of the original response in the calibration blank. If deviations greater than these are observed, flush the instrument with the rinse blank and monitor the responses in the calibration blank. If the responses of the internal standards are now within the limit, take a fresh aliquot of the sample, dilute by a further factor of two, add the internal standards and reanalyze. If after flushing the response of the internal standards in the calibration blank are out of limits, terminate the analysis and determine the cause of the drift. Possible causes of drift may be a partially blocked sampling cone or a change in the tuning condition of the instrument.

10.0 CALIBRATION AND STANDARDIZATION

10.1 Operating conditions - Because of the diversity of instrument hardware, no detailed instrument operating conditions are provided. The analyst is advised to follow the recommended operating conditions provided by the manufacturer. It is the responsibility of the analyst to verify that the instrument configuration and operating conditions satisfy the analytical requirements and to maintain quality control data verifying instrument performance and analytical results. Instrument operating conditions which were used to generate precision and recovery data for this method (Section 13.0) are included in Table 6.

10.2 Precalibration routine - The following precalibration routine must be completed prior to calibrating the instrument until such time it can be documented with periodic performance data that the instrument meets the criteria listed below without daily tuning.

10.2.1 Initiate proper operating configuration of instrument and data system. Allow a period of not less than 30 minutes for the instrument to warm up. During this process conduct mass calibration and resolution checks using the tuning solution. Resolution at low mass is indicated by magnesium isotopes 24, 25, and 26. Resolution at high mass is indicated by lead isotopes 206, 207, and 208. For good performance adjust spectrometer resolution to produce a peak width of approximately 0.75 amu at 5% peak height. Adjust mass calibration if it has shifted by more than 0.1 amu from unit mass.

10.2.2 Instrument stability must be demonstrated by running the tuning solution (Section 7.7) a minimum of five times with resulting relative standard deviations of absolute signals for all analytes of less than 5%.

10.3 Internal Standardization - Internal standardization must be used in all analyses to correct for instrument drift and physical interferences. A list of acceptable

internal standards is provided in Table 3. For full mass range scans, a minimum of three internal standards must be used. Procedures described in this method for general application, detail the use of five internal standards; scandium, yttrium, indium, terbium and bismuth. These were used to generate the precision and recovery data attached to this method. Internal standards must be present in all samples, standards and blanks at identical levels. This may be achieved by directly adding an aliquot of the internal standards to the CAL standard, blank or sample solution (Method A, Section 10.3), or alternatively by mixing with the solution prior to nebulization using a second channel of the peristaltic pump and a mixing coil (Method B, Section 10.3). The concentration of the internal standard should be sufficiently high that good precision is obtained in the measurement of the isotope used for data correction and to minimize the possibility of correction errors if the internal standard is naturally present in the sample. Depending on the sensitivity of the instrument, a concentration range of 20-200 µg/L of each internal standard is recommended. Internal standards should be added to blanks, samples and standards in a like manner, so that dilution effects resulting from the addition may be disregarded.

10.4 Calibration - Prior to initial calibration, set up proper instrument software routines for quantitative analysis. The instrument must be calibrated using one of the internal standard routines (Method A or B) described in Section 10.3. The instrument must be calibrated for the analytes to be determined using the calibration blank (Section 7.6.1) and calibration standards A and B (Section 7.4.1) prepared at one or more concentration levels. A minimum of three replicate integrations are required for data acquisition. Use the average of the integrations for instrument calibration and data reporting.

10.5 The rinse blank should be used to flush the system between solution changes for blanks, standards and samples. Allow sufficient rinse time to remove traces of the previous sample (Section 4.1.5). Solutions should be aspirated for 30 seconds prior to the acquisition of data to allow equilibrium to be established.

11.0 PROCEDURE

11.1 Aqueous Sample Preparation - Dissolved Analytes

11.1.1 For the determination of dissolved analytes in ground and surface waters, pipet an aliquot (≥20 mL) of the filtered, acid preserved sample into a 50 mL polypropylene centrifuge tube. Add an appropriate volume of (1+1) nitric acid to adjust the acid concentration of the aliquot to approximate a 1% (v/v) nitric acid solution (e.g., add 0.4 mL (1+1) HNO_3 to a 20 mL aliquot of sample). If the direct addition procedure (Method A, Section 10.3) is being used, add internal standards, cap the tube and mix. The sample is now ready for analysis (Section 1.2). Allowance for sample dilution should be made in the calculations.

Note: If a precipitate is formed during acidification, transport, or storage, the sample aliquot must be treated using the procedure in Section 11.2 prior to analysis.

11.2 Aqueous Sample Preparation - Total Recoverable Analytes

11.2.1 For the "direct analysis" of total recoverable analytes in drinking water samples containing turbidity <1 NTU, treat an unfiltered acid preserved sample aliquot using the sample preparation procedure described in Section 11.1.1 while making allowance for sample dilution in the data calculation. For the determination of total recoverable analytes in all other aqueous samples or for preconcentrating drinking water samples prior to analysis follow the procedure given in Sections 11.2.2 through 11.2.8.

11.2.2 For the determination of total recoverable analytes in aqueous samples (other than drinking water with <1 NTU turbidity), transfer a 100 mL (±1 mL) aliquot from a well mixed, acid preserved sample to a 250 mL Griffin beaker (Sections 1.2, 1.3, 1.7, and 1.8). (When necessary, smaller sample aliquot volumes may be used.)

Note: If the sample contains undissolved solids >1%, a well mixed, acid preserved aliquot containing no more than 1 g particulate material should be cautiously evaporated to near 10 mL and extracted using the acid-mixture procedure described in Sections 11.3.3 through 11.3.7.

11.2.3 Add 2 mL (1+1) nitric acid and 1.0 mL of (1+1) hydrochloric acid to the beaker containing the measured volume of sample. Place the beaker on the hot plate for solution evaporation. The hot plate should be located in a fume hood and previously adjusted to provide evaporation at a temperature of approximately but no higher than 85°C. (See the following note.) The beaker should be covered with an elevated watch glass or other necessary steps should be taken to prevent sample contamination from the fume hood environment.

Note: For proper heating adjust the temperature control of the hot plate such that an uncovered Griffin beaker containing 50 mL of water placed in the center of the hot plate can be maintained at a temperature approximately but no higher than 85°C. (Once the beaker is covered with a watch glass the temperature of the water will rise to approximately 95°C.)

11.2.4 Reduce the volume of the sample aliquot to about 20 mL by gentle heating at 85°C. DO NOT BOIL. This step takes about two hours for a 100 mL aliquot with the rate of evaporation rapidly increasing as the sample volume approaches 20 mL. (A spare beaker containing 20 mL of water can be used as a gauge.)

11.2.5 Cover the lip of the beaker with a watch glass to reduce additional evaporation and gently reflux the sample for 30 minutes. (Slight boiling may occur, but vigorous boiling must be avoided to prevent loss of the $HCl-H_2O$ azeotrope.)

11.2.6 Allow the beaker to cool. Quantitatively transfer the sample solution to

a 50 mL volumetric flask or 50 mL class A stoppered graduated cylinder, make to volume with reagent water, stopper and mix.

11.2.7 Allow any undissolved material to settle overnight, or centrifuge a portion of the prepared sample until clear. (If after centrifuging or standing overnight the sample contains suspended solids that would clog the nebulizer, a portion of the sample may be filtered for their removal prior to analysis. However, care should be exercised to avoid potential contamination from filtration.)

11.2.8 Prior to analysis, adjust the chloride concentration by pipetting 20 mL of the prepared solution into a 50 mL volumetric flask, dilute to volume with reagent water and mix. (If the dissolved solids in this solution are >0.2%, additional dilution may be required to prevent clogging of the extraction and/or skimmer cones. If the direct addition procedure (Method A, Section 10.3) is being used, add internal standards and mix. The sample is now ready for analysis. Because the effects of various matrices on the stability of diluted samples cannot be characterized, all analyses should be performed as soon as possible after the completed preparation.

11.3 Solid Sample Preparation - Total Recoverable Analytes

11.3.1 For the determination of total recoverable analytes in solid samples, mix the sample thoroughly and transfer a portion (>20 g) to tared weighing dish, weigh the sample and record the wet weight (WW). (For samples with <35% moisture a 20 g portion is sufficient. For samples with moisture >35% a larger aliquot 50-100 g is required.) Dry the sample to a constant weight at 60°C and record the dry weight (DW) for calculation of percent solids (Section 12.6). (The sample is dried at 60°C to prevent the loss of mercury and other possible volatile metallic compounds, to facilitate sieving, and to ready the sample for grinding.)

11.3.2 To achieve homogeneity, sieve the dried sample using a 5-mesh polypropylene sieve and grind in a mortar and pestle. (The sieve, mortar and pestle should be cleaned between samples.) From the dried, ground material weigh accurately a representative 1.0 ± 0.01 g aliquot (W) of the sample and transfer to a 250 mL Phillips beaker for acid extraction.

11.3.3 To the beaker add 4 mL of (1+1) HNO_3 and 10 mL of (1+4) HCl. Cover the lip of the beaker with a watch glass. Place the beaker on a hot plate for reflux extraction of the analytes. The hot plate should be located in a fume hood and previously adjusted to provide a reflux temperature of approximately 95°C. (See the following note.)

Note: For proper heating adjust the temperature control of the hot plate such that an uncovered Griffin beaker containing 50 mL of water placed in the center of the hot plate can be maintained at a temperature approximately but no higher than 85°C. (Once the beaker is covered with a watch glass the temperature of the water will rise to approximately

95°C.) Also, a block digester capable of maintaining a temperature of 95°C and equipped with 250 mL constricted volumetric digestion tubes may be substituted for the hot plate and conical beakers in the extraction step.

11.3.4 Heat the sample and gently reflux for 30 minutes. Very slight boiling may occur, however vigorous boiling must be avoided to prevent loss of the HCl-H_2O azeotrope. Some solution evaporation will occur (3-4 mL).

11.3.5 Allow the sample to cool and quantitatively transfer the extract to a 100 mL volumetric flask. Dilute to volume with reagent water, stopper and mix.

11.3.6 Allow the sample extract solution to stand overnight to separate insoluble material or centrifuge a portion of the sample solution until clear. (If after centrifuging or standing overnight the extract solution contains suspended solids that would clog the nebulizer, a portion of the extract solution may be filtered for their removal prior to analysis. However, care should be exercised to avoid potential contamination from filtration.)

11.3.7 Prior to analysis, adjust the chloride concentration by pipetting 20 mL of the prepared solution into a 100 mL volumetric flask, dilute to volume with reagent water and mix. (If the dissolved solids in this solution are >0.2%, additional dilution may be required to prevent clogging of the extraction and/or skimmer cones. If the direct addition procedure (Method A, Section 10.3) is being used, add internal standards and mix. The sample extract is now ready for analysis. Because the effects of various matrices on the stability of diluted samples cannot be characterized, all analyses should be performed as soon as possible after the completed preparation.

Note: Determine the percent solids in the sample for use in calculations and for reporting data on a dry weight basis.

11.4 Sample Analysis

11.4.1 For every new or unusual matrix, it is highly recommended that a semi-quantitative analysis be carried out to screen the sample for elements at high concentration. Information gained from this may be used to prevent potential damage to the detector during sample analysis and to identify elements which may be higher than the linear range. Matrix screening may be carried out by using intelligent software, if available, or by diluting the sample by a factor of 500 and analyzing in a semi-quantitative mode. The sample should also be screened for background levels of all elements chosen for use as internal standards in order to prevent bias in the calculation of the analytical data.

11.4.2 Initiate instrument operating configuration. Tune and calibrate the instrument for the analytes of interest (Section 10.0).

11.4.3 Establish instrument software run procedures for quantitative analysis. For all sample analyses, a minimum of three replicate integrations are required for data acquisition. Use the average of the integrations for data reporting.

11.4.4 All masses which might affect data quality must be monitored during the analytical run. As a minimum, those masses prescribed in Table 4 must be monitored in the same scan as is used for the collection of the data. This information should be used to correct the data for identified interferences.

11.4.5 During the analysis of samples, the laboratory must comply with the required quality control described in Sections 9.3 and 9.4. Only for the determination of dissolved analytes or the "direct analysis" of drinking water with turbidity of <1 NTU is the sample digestion step of the LRB, LFB, and LFM not required.

11.4.6 The rinse blank should be used to flush the system between samples. Allow sufficient time to remove traces of the previous sample or a minimum of one minute (Section 4.1.5). Samples should be aspirated for 30 seconds prior to the collection of data.

11.4.7 Samples having concentrations higher than the established linear dynamic range should be diluted into range and reanalyzed. The sample should first be analyzed for the trace elements in the sample, protecting the detector from the high concentration elements, if necessary, by the selection of appropriate scanning windows. The sample should then be diluted for the determination of the remaining elements. Alternatively, the dynamic range may be adjusted by selecting an alternative isotope of lower natural abundance, provided quality control data for that isotope have been established. The dynamic range must not be adjusted by altering instrument conditions to an uncharacterized state.

12.0 DATA ANALYSIS AND CALCULATIONS

12.1 Elemental equations recommended for sample data calculations are listed in Table 5. Sample data should be reported in units of µg/L for aqueous samples or mg/kg dry weight for solid samples. Do not report element concentrations below the determined MDL.

12.2 For data values less than 10, two significant figures should be used for reporting element concentrations. For data values greater than or equal to 10, three significant figures should be used.

12.3 For aqueous samples prepared by total recoverable procedure (Section 11.2), multiply solution concentrations by the dilution factor 1.25. If additional dilutions were made to any samples or an aqueous sample was prepared using the acid-mixture procedure described in Section 11.3, the appropriate factor should be applied to the calculated sample concentrations.

12.4 For total recoverable analytes in solid samples (Section 11.3), round the solution analyte concentrations (µg/L in the analysis solution) as instructed in Section 12.2. Multiply the µ/L concentrations in the analysis solution by the factor 0.005 to calculate the mg/L analyte concentration in the 100 mL extract solution. (If additional dilutions were made to any samples, the appropriate factor should be applied to calculate analyte concentrations in the extract solution.) Report the data up to three significant figures as mg/kg dry-weight basis unless specified otherwise by the program or data user. Calculate the concentration using the equation below:

$$\text{Sample Conc. (mg/kg) dry-weight basis} = \frac{C \times V}{W}$$

where:

C = Concentration in the extract (mg/L)
V = Volume of extract (L, 100 mL = 0.1L)
W = Weight of sample aliquot extracted (g x 0.001 = kg)

Do not report analyte data below the estimated solids MDL or an adjusted MDL because of additional dilutions required to complete the analysis.

12.5 To report percent solids in solid samples (Sect. 11.3) calculate as follows:

$$\% \text{ solids (S)} = \frac{DW}{WW} \times 100$$

where:

DW = Sample weight (g) dried at 60°C
WW = Sample weight (g) before drying

Note: If the data user, program or laboratory requires that the reported percent solids be determined by drying at 105°C, repeat the procedure given in Section 11.3 using a separate portion (>20 g) of the sample and dry to constant weight at 103-105°C.

12.6 Data values should be corrected for instrument drift or sample matrix induced interferences by the application of internal standardization. Corrections for characterized spectral interferences should be applied to the data. Chloride interference corrections should be made on all samples, regardless of the addition of hydrochloric acid, as the chloride ion is a common constituent of environmental samples.

12.7 If an element has more than one monitored isotope, examination of the concentration calculated for each isotope, or the isotope ratios, will provide useful information for the analyst in detecting a possible spectral interference.

Consideration should therefore be given to both primary and secondary isotopes in the evaluation of the element concentration. In some cases, secondary isotopes may be less sensitive or more prone to interferences than the primary recommended isotopes, therefore differences between the results do not necessarily indicate a problem with data calculated for the primary isotopes.

12.8 The QC data obtained during the analyses provide an indication of the quality of the sample data and should be provided with the sample results.

13.0 METHOD PERFORMANCE

13.1 Instrument operating conditions used for single laboratory testing of the method are summarized in Table 6. Total recoverable digestion and "direct analysis" MDLs determined using the procedure described in Section 9.2.4, are listed in Table 7.

13.2 Data obtained from single laboratory testing of the method are summarized in Table 9 for five water samples representing drinking water, surface water, ground water and waste effluent. Samples were prepared using the procedure described in Section 11.2. For each matrix, five replicates were analyzed and the average of the replicates used for determining the sample background concentration for each element. Two further pairs of duplicates were fortified at different concentration levels. For each method element, the sample background concentration, mean percent recovery, the standard deviation of the percent recovery and the relative percent difference between the duplicate fortified samples are listed in Table 8.

13.3 Data obtained from single laboratory testing of the method are summarized in Table 10 for three solid samples consisting of SRM 1645 River Sediment, EPA Hazardous Soil and EPA Electroplating Sludge. Samples were prepared using the procedure described in Section 11.3. For each method element, the sample background concentration, mean percent recovery, the standard deviation of the percent recovery and the relative percent difference between the duplicate fortified samples were determined as for Section 13.2.

13.4 Data obtained from single laboratory testing of the method for drinking water analysis using the "direct analysis" procedure (Section 11.2.1) are given in Table 11. Three drinking water samples of varying hardness collected from Regions 4, 6, and 10 were fortified to contain 1 µg/L of all metal primary contaminants, except selenium, which was added to a concentration of 20 µg/L. For each matrix, four replicate aliquots were analyzed to determine the sample background concentration of each analyte and four fortified aliquots were analyzed to determine mean percent recovery in each matrix. Listed in the Table 11 are the average mean percent recovery of each analyte in the three matrices and the standard deviation of the mean percent recoveries.

13.5 Listed in Table 12 are the regression equations for precision and bias developed from the joint USEPA/Association of Official Analytical Chemists (AOAC) multilaboratory validation study conducted on this method. These equations

were developed from data received from 13 laboratories on reagent water, drinking water and ground water. Listed in Tables 13 and 14, respectively, are the precision and recovery data from a wastewater digestate supplied to all laboratories and from a wastewater of the participant's choice. For a complete review of the study see Reference 11, Section 16.0 of this method.

14.0 POLLUTION PREVENTION

14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity or toxicity of waste at the point of generation. Numerous opportunities for pollution prevention exist in laboratory operation. The EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option.

14.2 For information about pollution prevention that may be applicable to laboratories and research institutions, consult “Less is Better: Laboratory Chemical Management for Waste Reduction”, available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th Street N.W., Washington D.C. 20036, (202)872-4477.

15.0 WASTE MANAGEMENT

15.1 The Environmental Protection Agency requires that laboratory waste management practices be conducted consistent with all applicable rules and regulations. The Agency urges laboratories to protect the air, water, and land by minimizing and controlling all releases from hoods and bench operations, complying with the letter and spirit of any sewer discharge permits and regulations, and by complying with all solid and hazardous waste regulations, particularly the hazardous waste identification rules and land disposal restrictions. For further information on waste management consult “The Waste Management Manual for Laboratory Personnel”, available from the American Chemical Society at the address listed in the Section 14.2.

17.0 TABLES, DIAGRAMS, FLOWCHARTS, AND VALIDATION DATA

TABLE 1: ESTIMATED INSTRUMENT DETECTION LIMITS

Element	Recommended Analytical Mass	Scanning Mode[1]	Selection Ion Monitoring Mode[2,3]
Aluminum	27	0.05	0.02
Antimony	123	0.08	0.008
Arsenic(3)	75	0.9	0.02
Barium	137	0.5	0.03
Beryllium	9	0.1	0.02
Cadmium	111	0.1	0.02
Chromium	52	0.07	0.04
Cobalt	59	0.03	0.002
Copper	63	0.03	0.004
Lead	206, 207, 208	0.08	0.015
Manganese	55	0.1	0.007
Mercury	202	n.a	0.2
Molybdenum	98	0.1	0.005
Nickel	60	0.2	0.07
Selenium(3)	82	5	1.3
Silver	107	0.05	0.004
Thallium	205	0.09	0.014
Thorium	232	0.03	0.005
Uranium	238	0.02	0.005
Vanadium	51	0.02	0.006
Zinc	66	0.2	0.07

Instrument detection limits (3σ) estimated from seven replicate integrations of the blank (1% v/v nitric acid) following calibration of the instrument with three replicate integrations of a multi-element standard.

[1]Instrument operating conditions and data acquisition mode are given in Table 6.

[2]IDLs determined using state-of-the-art instrumentation (1994). Data for ^{75}As, ^{77}Se, and ^{82}Se were acquired using a dwell time of 4.096 seconds with 1500 area count per sec ^{83}Kr present in argon supply. All other data were acquired using a dwell time of 1.024 seconds per AMU monitored.

TABLE 2: COMMON MOLECULAR ION INTERFERENCES IN ICP-MS

BACKGROUND MOLECULAR IONS		
Molecular Ion	**Mass**	**Element Interference[a]**
NH^+	15	
OH^+	17	
OH_2^+	18

$ArNa^+$	63	Cu
ArK^+	79	
$ArCa^+$	80	

TABLE 2: COMMON MOLECULAR ION INTERFERENCES IN ICP-MS (Cont'd)

MATRIX MOLECULAR IONS		
Molecular Ion	**Mass**	**Element Interference[a]**
Matrix Oxides[*]		
TiO	62-66	Ni, Cu, Zn
ZrO	106-112	Ag, Cd
MoO	108-116	Cd

[*]Oxide interferences will normally be very small and will only impact the method elements when present at relatively high concentrations. Some examples of matrix oxides are listed of which the analyst should be aware. It is recommended that Ti and Zr isotopes are monitored in solid waste samples, which are likely to contain high levels of these elements. Mo is monitored as a method analyte.

TABLE 3: INTERNAL STANDARDS AND LIMITATIONS OF USE

Internal Standard	Mass	Possible Limitation
^{6}Lithium	6	a
Scandium	45	polyatomic ion interference
Yttrium	89	a,b
Rhodium	103	
Indium	115	isobaric interference by Sn
Terbium	159	
Holmium	165	
Lutetium	175	
Bismuth	209	a

a May be present in environmental samples.

b In some instruments Yttrium may form measurable amounts of YO^{+} (105 amu)and YOH^{+} (106 amu). If this is the case, care should be taken in the use of the cadmium elemental correction equation.

Internal standards recommended for use with this method are shown in bold face. Preparation procedures for these are included in Section 7.3.

TABLE 4: RECOMMENDED ANALYTICAL ISOTOPES AND ADDITIONAL MASSES WHICH MUST BE MONITORED

Isotope	Element of Interest
27	Aluminum
121, 123	Antimony
75	Arsenic
135, 137	Barium
9	Beryllium
106, 108, 111, 114	Cadmium
52, 53	Chromium
59	Cobalt
63, 65	Copper
206, 207, 208	Lead
55	Manganese
95, 97, 98	Molybdenum
60, 62	Nickel
77, 82	Selenium
107, 109	Silver
203, 205	Thallium
232	Thorium
238	Uranium
51	Vanadium
66, 67, 68	Zinc
83	Krypton
99	Ruthenium
105	Palladium
118	Tin

NOTE: Isotopes recommended for analytical determination are underlined.

Zn	(1.000) (^{66}C)	

TABLE 5: RECOMMENDED ELEMENTAL EQUATIONS FOR DATA CALCULATIONS

Element	Elemental Equation	Note
Bi	(1.000) (^{209}C)	
In	(1.000) (^{209}C)-(0.016) (^{118}C)	(8)
Sc	(1.000) (^{45}C)	
Tb	(1.000) (^{159}C)	
Y	(1.000) (^{89}C)	

C - Calibration blank subtracted counts at specified mass.

(1) - Correction for chloride interference with adjustment for ^{77}Se. ArCl 75/77 ratio may be determined from the reagent blank. Isobaric mass 82 must be from Se only and not BrH^+.

(2) - Correction for MoO interference. Isobaric mass 106 must be from Cd only not ZrO^+. An additional isobaric elemental correction should be made if palladium is present.

(3) - In 0.4% v/v HCl, the background from ClOH will normally be small. However the contribution may be estimated from the reagent blank. Isobaric mass must be from Cr only not ArC^+.

(4) - Allowance for isotopic variability of lead isotopes.

(5) - Isobaric elemental correction for ruthenium.

(6) - Some argon supplies contain krypton as an impurity. Selenium is corrected for ^{82}Kr by background subtraction.

(7) - Correction for chloride interference with adjustment for ^{53}Cr. ClO 51/53 ratio may be determined from the reagent blank. Isobaric mass 52 must be from Cr only not ArC^+.

(8) - Isobaric elemental correction for tin.

TABLE 6: INSTRUMENT OPERATING CONDITIONS FOR PRECISION AND RECOVERY DATA[1]

Instrument	VG PlasmaQuad Type I
Plasma foward power	1.35 kW
Coolant flow rate	13.5 L/min.
Auxillary flow rate	0.6 L/min.
Nebulizer flow rate	0.78 L/min.
Solution uptake rate	0.6 mL/min.
Spray chamber temperature	15°C
Data Acquistion	
Detector mode	Pulse counting
Replicate integrations	3
Mass range	8-240 amu
Dwell time	320 µs
Number of MCA channels	2048
Number of scan sweeps	85
Total acquisition time	3 minutes per sample

[1]The described instrument and operating conditions were used to determine the scanning mode MDL data listed in Table 7 and the precision and recovery data given in Tables 9 and 10.

TABLE 7: METHOD DETECTION LIMITS

66 Zn	1.8	0.7	0.1	0.2

[1]Data acquisition mode given in Table 6. Total recoverable MDL concentrations are computed for original matrix with allowance for sample dilution during preparation. Listed MDLs for solids calculated from determined aqueous MDLs.

[2]MDLs determined using state-of-the-art instrumentation (1994). Data for ^{75}As, ^{77}Se, and ^{82}Se were acquired using a dwell time of 4.096 seconds with 1500 area count per seconds ^{83}Kr present in argon supply. All other data were acquired using a dwell time of 1.024 seconds per AMU monitored.

[3]MDLs were determined from analysis of seven undigested aqueous sample aliquots.

n.a. - Not applicable. Total recoverable digestion not suitable for organo-mercury compounds.

TABLE 8: ACCEPTANCE LIMITS FOR QC CHECK SAMPLE

METHOD PERFORMANCE (µg/L)[1]

Element	QC Check Sample Conc.	Average Recovery	Standard Deviation[2] (S_r)	Acceptance Limits[3] µg/L
Aluminum	100	100.4	5.49	84-117

TABLE 11: PRIMARY DRINKING WATER CONTAMINANTS PRECISION AND RECOVERY DATA

Analyte	Regional Sample Background Concentration, µg/L (IV)	(VI)	(X)	Average Mean[1] % Recovery	S (R)
Antimony	0.16	0.07	0.03	114%	1.9
Arsenic	< MDL	2.4	1.0	93	8.5
Barium	4.6	280	14.3	(*)	–
Beryllium	< MDL	< MDL	< MDL	100%	8.2
Cadmium	0.05	0.05	0.03	81	4.0
Chromium	0.71	5.1	0.10	94	2.5
Copper	208	130	14.3	(*)	–
Lead	1.2	1.2	2.5	91	2.6
Mercury	< MDL	0.23	< MDL	86	11.4
Nickel	1.7	3.6	0.52	101%	11.5
Selenium	< MDL	4.3	< MDL	98	8.4
Thallium	< MDL	0.01	< MDL	100	1.4

[1]The three regional waters were fortified with 1.0 µg/L of all analytes listed, except selenium, which was fortified to 20 µg/L.

(*) Recovery of barium and copper was not calculated because the analyte addition was <20% the sample background concentration in all waters. (Recovery calculations are not required if the concentration of the analyte added is less than 30% of the sample background concentration. Section 9.4.3).

S (R) Standard deviation of the mean percent recoveries.

Recommended Method for the DETERMINATION OF TOTAL MERCURY IN MARINE SAMPLES BY THERMAL DECOMPOSITION AMALGAMATION AND ATOMIC ABSORPTION SPECTROPHOTOMETRY

TABLE OF CONTENTS

NOTE: This method is not intended to be an analytical training manual. Therefore, this method is written with the assumption that it will be performed by formally trained analytical chemist.

In addition, the IAEA recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method, they shall not be used as absolute QC acceptance criteria.

1. SCOPE

The method hereinafter describes the protocol for the determination of total mercury (inorganic and organic) in sediment and biological material.

By using this method, the total mercury in solid samples can be determined without sample chemical pre-treatment.

The recommended protocol is mainly based on the EPA 7473 method; users are encouraged to consult this document (EPA, 2007).

2. PRINCIPLE

The sample is dried and then chemically decomposed under oxygen in the decomposition furnace. The decomposition products are carried out to the catalytic section of the furnace, where oxidation is completed (halogens and nitrogen/sulfur oxides are trapped). The mercury present in the remaining decomposition products is selectively trapped on an amalgamator. After flushing the system with oxygen, the mercury vapour is released by rapid heating of the amalgamator, and carried through the absorbance cell in the light path of a single wavelength atomic absorption spectrophotometer. The absorbance is measured at 253.7 nm as a function of mercury quantity (ng).

The typical working range is 0.1–500 ng. The mercury vapour is carried through a long (first) and a short path length absorbance cell. The same quantity of mercury is measured twice with different sensitivity resulting in a dynamic range that spans four orders of magnitude.

The typical detection limit is 0.01 ng of mercury.

3. SAMPLE PRE-TREATMENT

The sediment samples are prepared following the recommendations of UNEP (2005);

The marine organisms are prepared following the recommendations of UNEP (1984, 1994).

4. REAGENTS

The reagents used shall meet the purity requirement of the subsequent analysis

4.1. ULTRAPUR WATER (type MilliQ)

4.2. NITRIC ACID 65%

4.3. POTASSIUM DICHROMATE OXIDIZING SOLUTION (10% w/v)

Weight 25 g of $K_2Cr_2O_7$ in 250 ml glass bottle, fill it up to 250 ml with water, and shake until total dissolution of solids. Keep the bottle tightly closed in a double plastic bag, and in an Hg free environment (i.e. laminar flow hood). This solution is stable indefinitely and rarely becomes contaminated.

4.4. COMMERCIAL STANDARD SOLUTION 1000 µg ml^{-1} MERCURY

Use a certified reference material solution; this solution should be accompanied by a certificate stipulating at minimum the traceability of the certified concentration, as well as the expiry date. The density of the solution, or the certified content in mg kg^{-1} should also be defined, to allow for the preparation of the calibration solution by weighing. Stock solutions should be kept at 5°C.

5. MATERIAL

5.1. SOLID MERCURY ANALYZER

Optionally equipped with an auto-sampler.

5.2. ANALYTICAL BALANCE

With a 0.001 g precision at least.

5.3. VOLUMETRIC CONTAINERS

Preferably in Teflon or glass.

5.4. PIPETTES

Some microliter pipettes sized ranging from 50 to 10000 µl are needed. The accuracy and precision of the pipettes used should be checked as a routine every 6 months, and the results obtained should be compared with the individual certificates.

5.5. METAL SPATULA (inox).

5.6. SAMPLE BOAT

Metal or metal alloy. Before measurement, sample boats are cleaned by heating over a flame until constant “red” to remove mercury.

5.7. OXYGEN

It should be of high purity and free of mercury. If there is a possible mercury contamination from oxygen, install a gold mesh filter between the cylinder and the instrument to prevent any mercury from entering the instrument.

6. CALIBRATION

6.1. PRIMARY CALIBRATION. This is the calibration of the instrument working range. This calibration is performed initially (usually done by the manufacturer and stored in the instrument), and/or when any significant instrumental parameters are changed (i.e. after maintenance).

6.2. PREPARE STANDARD SOLUTIONS of appropriate concentration by dilution of a commercial standard (see 4.4). It is recommended to prepare standard solution in Teflon or glass container, in 1 or 0.5% HNO_3 (see 4.2) and 0.1% (v/v) potassium dichromate (see 4.3). Fresh mercury standard should be prepared daily. Prepare a zero calibration solution using the same quantity of acid and potassium dichromate.

6.3. START THE INSTRUMENT according to the manufacturer recommendations.

6.4. CLEAN THE SYSTEM. Inject 100 µl of water and start the measurement with the recommended parameters (see 7.1). Repeat the cleaning until the absorbance is below 0.001ABS.

6.5. SET THE INSTRUMENT PARAMETERS (see 7.1) for selected volume (usually 100 µl) and inject the zero calibration, at least three measurements should be done. The zero solution serves to correct the amount of mercury in water and reagent used for preparing the calibration curve, hence the important of keeping the injected volume equal at all points of the calibration curve. If the amount of mercury in the zero calibration is high (i.e. more than 0.01 ng), it is recommended to check for contamination sources and to prepare new standard solution with clean acid.

6.6. STANDARDS ARE MEASURED from the lowest to the highest at least twice. The maximum relative standard deviation between readings should be 3% (except for zero calibration); if higher it is recommended to carry out more measurements.

6.7. EXAMPLE OF AMOUNTS used for recalibration (primary):

First Range:

Standard (ng ml^{-1})	1	3	10	30	100	300
Volume injected (µl)	100	100	100	100	100	100
Quantity of Hg (ng)	0.1	0.3	1	3	10	30

Second Range:

Standard (µg ml^{-1})	1	2	3	4	5	6
Volume injected (µl)	100	100	100	100	100	100
Quantity of Hg (ng)	100	200	300	400	500	600

Note: The calibration of the second range might induce problems for subsequent analysis, due to the relatively high quantity of mercury introduced (especially with memory effect). It should be performed only if there is a probability of using it (i.e. measuring samples with high mercury level > 1µg g^{-1}). After the reading of the last calibration point, clean the system (see 6.4).

6.8. ALTERNATIVE CALIBRATION CURVE can be performed using a solid certified reference material. In this case, weigh accurately a CRM onto a tare sample boat, set up the instrument according to the sample type (see 7.1) and measure the absorbance. The matrix of the CRM should be as similar as possible to the sample of interest. Repeat this procedure with different weights of the CRM and/or with different CRM, to get results in the desired working range.

6.9. CONSTRUCT A CALIBRATION CURVE by plotting the absorbance against Nano grams of mercury (this could be done automatically by the software). The type of equation will depend on the levels, as the response is not linear over the entire working range.

6.10. DAILY CALIBRATION: calibration performed every day with a minimum number of standards to ensure that the primary calibration is valid. It can be performed by using either liquid standard (see 6.2) or solid certified reference material (CRM) see 6.8. It should be performed in the range of interest, with at least two standards (or matrix CRM) and the results should agree within the acceptance criteria. The acceptance criteria should be set through the use of historical data, but the maximum deviation should not exceed 10%.

7. PROCEDURE

7.1. GENERAL ANALYTICAL PARAMETERS

The analytical parameters will depend on the sample size and matrix, and are instrument specific. It is important to follow the guidelines from the instrument manufacturer. There are three time to set: drying, decomposition and waiting.

Some typical recommended conditions below:

Drying time:

Sample type	Dry (s)	Comments
Liquid	0.7 x injected Volume (µl)	
Dry inorganic	10	
Organic liquid	50–300	To be optimized[1]
Dry organic (i.e. fat)	50–200	To be optimized[1]
Wet (i.e. fresh)	0.7 x weight x % moisture	Example: 100 mg with 45% moisture 0.7 x 100 x 0.45= 31.5s (35)

[1] In the case of organic, there is a risk of explosion especially with organic liquid; to optimize set the instrument at: 300s dry/ 150s decomposition/ 45s wait, do the measurement and check for possible small explosion, note the time of the phenomenon and add to the drying time 10s more.

Decomposition time:

Sample type	Decomposition (s)	Comments
Liquid	150–400	To be optimized[1]
Solid inorganic	120 + 0.4 x sample (mg)	To be optimized[1]
Solid organic	120	

[1] Set the instrument to XX (see above) dry/ 400s decomposition/ 45s wait, run a sample and observe the results. Decrease the decomposition time by 30s and repeat measurement. Continue until you observe a significant decrease, note that time and add to the decomposition time 30s more.

Waiting time:

It is recommended to use 40–45s, except for long decomposition time (over 200s) when it is beneficial to add 10s of waiting for every 100s of decomposition.

Note: These indications above are recommended by ALTECH (AMA 254).

7.2. ANALYSIS OF A SOLID SAMPLE

Weight a sample accurately onto a tare boat, insert the boat into the instrument, set the appropriate parameters (see 7.1) and start the measurements. The results can be records on absorbance, quantity or concentration depending on the instrument software. See 9: Calculation of results.

7.3. ANALYSIS OF BLANK FOR SOLID MEASUREMENT

Analyse an empty sample boat using the same instrument settings than for the sample.

7.4. ANALYSIS OF A LIQUID SAMPLE

Dose a known volume of the sample onto a sample boat, set the appropriate parameters (see 7.1) and start the measurements. The results can be records on absorbance, quantity or concentration depending on the instrument software. See the calculation section (see 9).

7.5. ANALYSIS OF BLANK FOR LIQUID

Repeat 7.4 with the same volume of blank solution (solution that contain the same reagent and chemical than the sample).

8. QUALITY CONTROL

8.1. For every day of analysis, the CALIBRATION SHOULD BE VALIDATED by doing a daily calibration (see 6.10) before starting the measurements. The results of the daily calibration should be recorded for quality control purposes.

8.2. CERTIFIED REFERENCE MATERIAL

At least one certified reference material of a representative matrix should be measured with each batch of the sample, the calculated results should fall in the value of the certificate and within the coverage uncertainty (Linsinger, 2010), to show evidence of unbiased results. The results for the CRM should be recorded for quality control purpose and plotted in a control chart (UNEP/IOC/IAEA 1994).

8.3. A DUPLICATE OR TRIPLICATE SAMPLE should be processed on a routine basis.

A duplicate sample should be processed with each analytical batch or for every 10 samples.

8.4. A SPIKED SAMPLE should also be included, whenever a new sample matrix is being analysed, especially if no certified reference material is available for that matrix. Measure a spiked sample by adding a known volume of standard solution (prepared as in paragraph 6.2) to the sample in the boat. Keep the spike volume small enough not to overspill. The recovery of spike calculated with the equation 2 should be 85–115% (this limits should be reset after collection of historical data). If the test fails, it is recommended to check the calibration (see 6.10) and/or to revise the instrument parameters (see 7.1).

$$\text{Spike (ng)} = \text{Concentration of standard (ng/ml)} \times \text{Volume of spike (ml)} \qquad \text{Equation 1}$$

$$\text{Recovery (\%)} = \frac{\text{Spiked sample (ng)} - \text{Unspiked sample (ng)}}{\text{Spike (ng)}} \times 100 \qquad \text{Equation 2}$$

To be valid the quantity of Spike (equation 1) should be in the range of 50–150% the quantity of unspiked sample.

9. CALCULATION OF RESULTS

9.1. SOLID SAMPLE RESULTS are calculated using equation 3

$$w(Hg) = \frac{(\rho 1 - \rho 0)}{\mathrm{m}} \times R \qquad \text{Equation 3}$$

Where:

w(Hg) is the mass fraction of element m in the sample, expressed in mg kg^{-1};

ρ1 is the quantity of mercury, expressed in ng as measured in the sample;

ρ0 is the quantity of mercury expressed in ng as measured in the blank (see 7.3);

R is the recovery calculated using the CRM (see 8.2) or spike (see 8.4);

m is the amount of sample in mg.

Note: ρ1 and ρ0 are calculated using calibration curve equation (usually done by software).

9.2. LIQUID SAMPLE RESULTS are calculated using equation 4

$$w(Hg) = \frac{\frac{(\rho 1 - \rho 0)}{Vi} \times V}{\mathrm{m}} \times f \times R \qquad \text{Equation 4}$$

Where:

w(Hg) is the mass fraction of mercury in the sample, expressed in mg kg^{-1};

ρ1 is the quantity of mercury, expressed in ng as measured in the sample solution;

ρ0 is the quantity of mercury expressed in ng as measured in the blank solution (see 7.4);

R is the recovery calculated using the CRM (see 8.2) or spike (see 8.4);

Vi is the injected volume (should be the same in sample and blank solution) in ml;

m is the amount of sample in mg;

V is the volume of solution in ml;

f is the dilution factor.

Note: ρ1 and ρ0 are calculated using calibration curve equation (usually done by software).

10. EXPRESSION OF RESULTS

The rounding of values will depend on the uncertainty reported with the results; in general for this method two or three significant figures should be reported.

The uncertainty component should be reported with all results. (ISO 2005, Nordtest 2004)

Example: w(Hg) = 0.512 ± 0.065 mg kg^{-1}.

RECOMMENDED METHOD ON THE DETERMINATION OF TOTAL MERCURY IN SAMPLES OF MARINE ORIGIN BY COLD VAPOUR ATOMIC ABSORPTION SPECTROMETRY

TABLE OF CONTENT

<u>NOTE:</u> This method is not intended to be an analytical training manual. Therefore, the method is written with the assumption that it will be used by formally trained analytical chemists.

In addition, the IAEA recommended methods are intended to be guidance methods that can be used by laboratories as a starting point for generating their own standard operating procedure. If performance data are included in the method they must not be used as absolute QC acceptance criteria.

1. SCOPE

This method describes a protocol for measurement of total mercury by cold vapour atomic absorption spectrometry (CV-AAS). The method is simple, rapid and applicable to a large number of environmental samples. This method is applicable when the element content in the digested solution is above the method limit (~ 0.15 ng ml^{-1} depending on instrument). The typical working range is 0.25–100 ng ml^{-1} for direct injection of cold vapour, using "batch system"; FIAS or amalgamation accessory will give better sensitivity.

2. PRINCIPLE

The sediment or biological samples are mineralized with strong acids. The inorganic mercury is reduced to its elemental form with stannous chloride. The cold mercury vapour is then passed through the quartz absorption cell of an atomic absorption spectrometer (AAS), where its concentration is measured. The light beam of Hg hallow cathode lamp is directed through the quartz cell, into a monochromator and onto a detector that measures the amount of light absorbed by the atomized vapour in the cell. The amount of energy absorbed at the characteristic wavelength is proportional to the concentration of the element in the sample.

3. REAGENT

The reagents used shall meet the purity requirement of the subsequent analysis:

3.1. WATER

Reagent water (referenced also as water in the text) should be free of contamination.

3.2. NITRIC ACID 65%

3.3. HYDROCHLORIC ACID (37%)

3.4. HYDROGEN PEROXIDE

3.5. VANADIUM PENTOXIDE (V_2O_5)

3.6. SILICON ANTI-FOAMING

3.7. HYDROXYLAMINE HYDROCHLORIDE ($NH_2OH.HCl$)

Dissolve 12.0 g of $NH_2OH.HCl$ in 100 ml reagent water. This solution may be purified by the addition of 0.1 ml of $SnCl_2$ solution and purging 1 hour with Hg-free argon.

3.8. POTASSIUM DICHROMATE OXIDIZING SOLUTION (10% w/v)

Weight 25 g of $K_2Cr_2O_7$ in a 250 ml glass bottle, fill it up to 250 ml with water, and shake until total dissolution of the solid. Keep the bottle tightly closed in a double plastic bag, and in an Hg free environment (i.e. laminar flow hood). This solution is stable indefinitely and rarely becomes contaminated.

3.9. BrCl OXIDIZING SOLUTION

Weigh accurately 11 g of KBrO3 and 15 g of KBr into a clean 1 liter glass bottle. Add 200 ml of Milli-Q water; add carefully 800 ml of concentrated HCl. The dilution has to be carried out in a well-ventilated fume hood to prevent exposure to toxic fumes released during dissolution of KBrO3. Keep the bottle wrapped in aluminium foil, tightly closed in a double plastic bag, and in an Hg free environment (i.e. laminar flow hood). This solution is stable indefinitely but can become contaminated.

3.10. STANNOUS CHLORINE SOLUTION 20% (w/v) in 20% (w/v) HCl

Weigh 20 g of $SnCl_2$ in a 100 ml volumetric flask; add 20 ml of concentrated HCl; dissolve the $SnCl_2$ (if needed heat at 60°C for a few minutes on a hot plate); complete to 100 ml with water. This solution might be purified by bubbling with Hg-free argon for 15 minutes. The obtained solution should be clear and transparent, cloudy or yellow solution indicates a bad quality $SnCl_2$. This solution should be prepared fresh every day preferably, if not it should be kept in the fridge.

Note: The concentration of this solution is dependent on the type of accessory use for vapour generation, and can vary between 5 and 30%, the recommendation of the manufacturer

should be followed (i.e. the solution above is recommended for a VGA-70 from Varian). The validity of the solution (i.e. shelf-life) should be defined during method validation.

3.11. COMMERCIAL STANDARD SOLUTION 1000 µg ml^{-1}

Use a certified reference material solution; this solution should be accompanied by a certificate stipulating at minimum the traceability of the certified concentration, as well as the expiry date. The density of the solution, or the certified content in mg kg^{-1} should also be defined, to allow for the preparation of the calibration solution by weighing. Stock solutions should be kept at 5°C.

3.12. ARGON

Use of a gas purifier cartridge for removing mercury, oxygen and organic compounds is recommended.

4. MATERIAL

This section does not list the common laboratory glassware.

4.1. ATOMIC ABSORPTION SPECTROPHOTOMETER

Instrument equipped with an appropriate cold vapour generation system and a quartz or glass tube atomizer. Use a hollow cathode lamp or, preferably, an electrodeless discharge lamp (which gives a greater and more stable light intensity), operated at a current recommended for the lamp and by the instrument manufacturer. An AAS system with background correction device is recommended.

4.2. GLASSWARE

All the glassware, polypropylene, or fluorocarbon (PFA or TFM) containers, including the sample bottles, flasks and pipettes tips, should be washed in the following sequence:

- 24 hrs soaking in a laboratory soap (or 10% alcohol);
- followed by 24 hrs soaking in 10% nitric acid;
- followed by 10% soaking in water;
- final rinse in water; and
- drying under a laminar flow hood.

The cleaned items should be kept in a double sealed plastic bag. It is better to avoid storage of low level (< 5 ng ml^{-1}) solution in plastic, and for this purpose glass or Teflon is recommended.

If it can be documented, through an active analytical quality control program, using spiked samples and method blanks, then certain steps in the cleaning procedure would not be needed for routine samples, those steps may be eliminated from the procedure (i.e. for the levels

measured by flame AAS, some sterile plastic containers are sufficiently free of contamination for certain analytes).

4.3. PIPETTES

Some microliter pipettes size ranging from 50 to 10000 µl are needed. The accuracy and precision of the pipettes used should be checked as a routine every 6 months, and the results obtained should be compared with the individual certificates.

4.4. VOLUMETRIC CONTAINERS of suitable precision and accuracy.

5. INTERFERENCES

5.1. IODIDE, GOLD AND SILVER are known interferences for mercury determination by cold vapour. In samples from marine origin (biota or sediment), the levels of those elements are low, and consequently, do not interfere in the measurement process.

5.2. WATER VAPOUR (moisture) should be avoided in the measurement cell, always follow the manufacturer's protocol (e.g. use of membrane drying tube, correct position of gas separator…) and check for absence of moisture in the measurement cell.

5.3. When using GOLD AMALGAMATION, and with certain batch systems, the excess of oxidant can cause interference or damage the gold amalgamator, it is then recommended to pre-reduce the samples with hydroxylamine ammonium (see 3.7). This is important when using large amount of digested solution in "batch system".

5.4. Some samples (i.e. plants or large amount of mussels) might produce FOAM during the reduction reaction. If the amount of foam is important, it can interfere with gas liquid separation, and/or leak in the measurement cell, this phenomenon can be overcome by using silicon anti-foaming inside the gas liquid separator and/or in the "batch" system. Another option is to use vanadium pentoxide during digestion (see 6.4).

5.5. REDUCTION of inorganic mercury will induce loss, so it is important to stabilise all the solutions by using a strong oxidant as dichromate or BrCl (see 3.8 or 3.9).

6. SAMPLE PREPARATION

6.1. The sample should be prepared according to the recommended method for digestion of marine samples for the determination of trace metal (IAEA, 2011), but before diluting to the final volume (or weight) with water, add an adequate volume of potassium dichromate or BrCl to get the final concentration of 2% or 1% respectively. All the samples from marine origin (sediment or biota) can be prepared using the acid mixture recommended for fish, as Hg is not attached to silicates. For microwave digestion of sample size above 0.8 g, it is strongly recommended to do cold digestion for at least 5 hours and to use a long ramping time (i.e. 25 minutes) to avoid strong reactions in the microwave vessels.

6.2. If other trace elements have to be determined in the digested solution prepared according to the recommended method for digestion of marine samples for the determination of trace metal (IAEA, 2011), following the dilution to the final volume or weight, transfer a quantitatively sufficient amount of digested solution (i.e. at least 10 ml) into a separate container (preferably glass or Teflon), and add an oxidising solution 1% (v/v) of BrCl (see 3.9) or 2% (v/v) of potassium dichromate (see 3.8). Record the amount of oxidising solution added in order to calculate the dilution factor (i.e. dilution factor =1.01 for 0.1 ml of dichromate in 10 ml).

6.3. Alternatively, the samples can be digested using a mixture of 5 ml of HNO_3 and 2 ml of H_2O_2 at 90°C for 4 hours on a hot plate. It is recommended to leave the samples in acid at room temperature, for at least 1 hour before heating. The digestion can be performed either in a Teflon or glass closed containers. After cooling, add an adequate volume of potassium dichromate or BrCl to get the final concentration of 2% or 1% respectively, and dilute to the final volume with water (i.e. for 50 ml final volume, add 1 ml of potassium dichromate or 0.5 ml of BrCl solution). This procedure can be used with bigger sample size if needed (i.e. 2 g); in this case, the volume of nitric acid should be increased to obtain a liquid mixture.

6.4. In the case that the digested solution produces foam during the reduction process (see 5.4), 45 mg of vanadium pentoxide should be added in the digestion vessels before addition of the acid mixture, then follow either paragraph 6.1 or 6.3.

7. PROCEDURE

7.1. SAMPLE SOLUTION

Use the sample prepared with one option as described in section 6.

7.2. BLANK SOLUTION

Prepare at least two blank solutions with each batch of sample, using the same procedure than for the samples.

7.3. PREPARATION OF CALIBRATION SOLUTIONS

7.3.1. Before each batch of determination, prepare by the appropriate dilution of 1000 µg ml^{-1} stock standard solution (see 3.11), at least 4 standard solutions and one calibration blank solution, covering the appropriate range of the linear part of the curve. The calibration standards and calibration blank should be prepared using the same type of acid and oxidising solution than in the test portion (the final concentration should be similar).

7.3.2. Calibration solutions should be prepared fresh each day.

7.3.3. If the necessary intermediate stock standard solutions can be prepared in 5% nitric acid and 1% BrCl or 2% $K_2Cr_2O_7$, these solutions should be prepared monthly.

7.3.4. All volumetric material (pipettes and containers) should be of appropriate precision and accuracy, if not available standard solution can be prepared by weighing.

7.4. INSTALLATION OF VAPOUR GENERATOR ACCESSORY

7.4.1. Install the accessory according to the manufacturer's instructions. Certain systems (i.e. VGA from Varian) are designed to be used for hydride generation as well, and require in the instructions to aspirate an extra HCl solution, in the case of stannous chlorine reduction this solution is to be replaced by water. It is recommended to separate the systems used for hydride and for $SnCl_2$ (i.e. use a spare gas liquid separator and Teflon tubing).

7.4.2. Switch on the argon. For on-line system: start the pump, check the aspiration, and verify the gas liquid separator. If needed replace the pump tubing, clean the gas liquid separator by sonication in diluted detergent.

7.4.3. Clean the system by aspirating reagent and 10% nitric acid as a sample for about 10 minutes. For batch system, perform two cycles with 10% nitric acid.

7.4.4. Set up the atomic absorption spectrometer according to the manufacturer's instructions, at the appropriate wavelength, using the appropriate conditions, and with the suitable background correction system in operation.

7.4.5. Optimise the position of the measurement cell to get the maximum signal.

7.4.6. Connect the vapour generation system to the measurement cell.

7.5. CALIBRATION

7.5.1. Adjust the response of the instrument to zero absorbance whilst aspirating water.

NOTE: if the instrument zero reading is more than 0.002 ABS, the system should be clean again and reagent should be checked.

7.5.2. Aspirate the set of calibration solutions in ascending order, and as a zero member, the blank calibration solution. After the last standard, aspirate 10% nitric acid for 1 minute to rinse the system.

NOTE: The calibration curve is automatically plotted by the instrument software. The obtained curve should be linear with r>0.995.

To correct for the instrumental drift, the calibration should be performed every 20 samples or if the calibration verification has failed (see 7.8.1).

7.6. ASPIRATE SAMPLE BLANK (see 7.2) AND SAMPLE SOLUTIONS (see 7.1)

Record their concentrations as calculated by the software using the calibration curve. Rinse the system by aspirating 10% nitric acid for at least 30 s between samples.

7.7. IF THE CONCENTRATION OF THE TEST PORTION EXCEEDS THE CALIBRATION RANGE, dilute the test portion with the blank solution accordingly.

NOTE: After the measurement of high level (or over calibration) sample, measure a sample blank or water to check the absence of memory effect. If necessary, clean the system for 1 minute with 10% nitric acid.

7.8. QUALITY CONTROL SOLUTIONS

The quality control solutions as described below should be measured during the run.

7.8.1. Calibration Verification CV

After the initial calibration, the calibration curve must be verified by the use of initial calibration verification (CV) standard.

The CV standard is a standard solution made from an independent (second source) material, at/or near midrange. This solution as a calibration standard should be prepared using the same type of acid and oxidising solution than in the test portion (the final concentration should be similar).

The acceptance criteria for the CV standard must be ±10% of its true value.

If the calibration curve cannot be verified within the specified limits, the causes must be determined and the instrument recalibrated before the samples are analysed. The analysis data for the CV must be kept on file with the sample analysis.

The calibration curve must also be verified at the end of each analysis batch and/or after every 10 samples. If the calibration cannot be verified within the specified limits, the sample analysis must be discontinued, the causes must be determined and the instrument recalibrated. All samples following the last acceptable test must be reanalysed.

7.8.2. Blank solution (see 7.2)

The maximum allowed blank concentration should be well documented, and if the blank solution exceeds this value all samples prepared along the contaminated blank should be prepared again and reanalysed.

7.8.3. Post digestion spike

Each unknown type of sample should be spiked to check for potential matrix effect.

This spike is considered as a single point standard addition, and should be performed with a minimum dilution factor. The recovery of spike calculated with equation 1 should be 85-115%. If this test fails, it is recommended to run analysis with standard addition method.

Spike solution: mix a fix volume (V1) of the sample solution, and a known volume (V2) of a standard solution with known concentrations (Cstandard).

Unspike solution: mix the same fix volume (V1) of sample solution, and the same volume (V2) of reagent water.

Measure the concentration C (mg l^{-1}) in both solutions on the calibration curve (see 7.6), and calculate recovery as:

$$Cspike = \frac{Cstandard \times V2}{(V1+V2)} \qquad \text{Equation 1}$$

$$R = \frac{C\ Spike\ Solution - C\ Unspike\ solution}{Cspike} \times 100 \qquad \text{Equation 2}$$

To be valid, the concentrations of spiked and unspiked solutions should be in the linearity range of the calibration curve, and the spiked concentration (equation 1) should be in the range of 50-150% of the concentration of the unspiked solution.

7.8.4. Dilution test

If the analyte concentration is sufficiently high (minimally, a factor of 10 above the lower limit of the quantitation following dilution), an analysis of a 1:5 dilution should agree within

±10% of the original determination. If not, then a chemical or physical interference effect should be suspected, and method of standard addition is recommended.

7.8.5. Certified Reference Material

At least one certified reference material of a representative matrix should be prepared with each batch of sample, the calculated result should fall in the value of the certificate and within the coverage uncertainty (Linsinger, 2010), to show evidence of an unbiased result.

The results for the CRM should be recorded for quality control purpose and plotted on a control chart (UNEP/IOC/IAEA 1994).

An example of sequence order with recommended criteria and actions is given in table 1.

TABLE 1. EXAMPLE OF AN ANALYTICAL SEQUENCE:

Solutions Description	Performance	Action
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1–4	r>0.995	recalibrate in the linearity range
CV	±10% of the true value	Stop until resolve
Sample blank	< maximum allowed blank value	
CRM	Fall in the certificate value within coverage uncertainty, or fall within acceptable criteria of the QC chart	Stop until resolve, check Matrix spike and run again with standard addition method if necessary
Matrix Spike	recovery 100% ± 15%	switch to standard addition, keep records for future analysis of the same matrix
Dilution Test	sample 1 = 5x sample 1 diluted 5x within 10%	switch to standard addition, keep records for future analysis of the same matrix
Unknown Sample 1–10	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute
CV	±10% of the true value	Stop until resolve
Unknown Sample 11–20	should ≥ standard 1 and ≤ standard 4	report as <minimum quantification limit or dilute
Calibration blank	< maximum allowed calibration blank value	Stop until resolve
Standard solution 1–4	r>0.995	recalibrate in the linearity range
CV	±10% of the true value	Stop until resolve
Etc….		

8. CALCULATION OF RESULTS

Results are calculated using equation 3

$$w(m) = \frac{(\rho 1 - \rho 0)}{\mathrm{m}} \times f \times V \times R \qquad \text{Equation 3}$$

Where:

w(m) is the mass fraction of element m in the sample, expressed in mg kg^{-1};

ρ1 is the concentration of element m, expressed in mg/l as measured in the sample solution;

ρ0 is the concentration of element m expressed in mg/l as measured in the blank solution;

F is the dilution factor calculated as follow:

$$f = \frac{final\ volume}{initial\ volume}$$

or equal to 1 if ρ1 is determined in undiluted solution;

R is the recovery calculated using the CRM (see 7.8.5) or the post digestion spike.

m is the mass of sample in g

V is the volume of solution in ml

9. EXPRESSION OF RESULTS

The rounding of values will depend on the uncertainty reported with the result; in general for this method two or three significant figures should be reported.

Uncertainty component should be reported with all results. (ISO 2005, Nordtest 2004)

Example: w(Hg) = 0.512 ± 0.065 mg kg^{-1}.

HELCOM

Manual for marine monitoring in the COMBINE programme
ATTACHMENT 1. TECHNICAL NOTE ON THE DETERMINATION OF TOTAL MERCURY IN MARINE BIOTA BY COLD VAPOUR ATOMIC ABSORPTION SPECTROSCOPY

HELCOM Manual for marine monitoring in the COMBINE programme

ATTACHMENT 1. TECHNICAL NOTE ON THE DETERMINATION OF TOTAL MERCURY IN MARINE BIOTA BY COLD VAPOUR ATOMIC ABSORPTION SPECTROSCOPY

1. POSSIBILITIES OF USING COLD VAPOUR ATOMIC ABSORPTION SPECTROMETRY IN TOTAL MERCURY ANALYSIS

The most widely used method for the determination of total mercury in biological tissues is cold vapour atomic absorption spectrometry (CV-AAS), based on a technique elaborated in detail by Hatch and Ott (1968). In this method, (divalent) ionic mercury is reduced to its metallic form (Hgo) in acidic solution using a powerful reducing agent. Subsequently, the elemental mercury is volatilized (purged) by a carrier gas and transported into an absorption cell, where the 253.65 nm wavelength absorbance of mercury atoms is measured.

CV-AAS analysis can be performed manually using batch CV-AAS or automatically using flow injection (FI) techniques. FI is a very efficient approach for introducing and processing liquid samples in atomic absorption spectrometry. The FI technique, combined with a built-in atomic absorption spectrometer optimised for mercury determination, reduces sample and reagent consumption, has a higher tolerance of interferences, lower determination limits and improved precision compared with conventional cold vapour techniques.

The efficiency of various flow injection mercury systems has been reported by several groups (Tsalev *et al*., 1992a, 1992b; Welz *et al*., 1992; Guo and Baasner, 1993; Hanna and McIntosh, 1995; Kingston and McIntosh, 1995; Lippo *et al*., 1997). Better sensitivities of both conventional CV-AAS and FI-CV-AAS can be obtained by collecting mercury vapour released from the sample solution on a gold adsorber (Welz and Melcher, 1984). This so-called amalgamation technique eliminates kinetic interferences due to a different vaporization rate or a different distribution function of the elemental mercury between the liquid and the gaseous phases. The amalgamation ability of the gold adsorber must be carefully and regularly checked. Volatile compounds (in particular sulfur-containing compounds) evaporating together with the elemental mercury from the sample solution may deactivate the adsorber surface. This means an increased risk of underestimation, as unknown quantities of mercury are not collected by the adsorber.

2. SAMPLE PRETREATMENT

It is generally agreed that oxidative conversion of all forms of mercury in the sample to ionic Hg(II) is necessary prior to reduction to elemental Hg and its subsequent measurement by CV-AAS. Therefore, the initial procedural step in mercury analysis is a sample pretreatment, which is aimed at liberating the analyte element from its chemical bonding to the organic matrix and thus transforming all of the analyte species into a well-defined oxidation state. For this purpose, a wide variety of combinations of strong acids (HCl, H2SO4, HNO3) and oxidants (H2O2, KMnO4, K2Cr2O7, K2S2O8) have been tested and recommended (Kaiser *et al*., 1978; Harms, 1988; Vermeir*et al*., 1989; Ping and Dasgupta, 1989; Baxter and Frech, 1990; Landi *et al*., 1990; Navarro *et al*., 1992; Lippo *et al*., 1997).

A suitable sample pretreatment, which implies the complete transformation of all organomercury species into inorganic mercury ions, requires the following:

- oxidation mixtures with a high oxidation potential;
- rapid oxidation (usually promoted by high reaction temperatures), preferably in closed systems;

- compatibility with CV-AAS techniques;
- stability of sample solutions during storage (at least short term);
- no formation of solid reaction products.

On-line sample pretreatment is of particular interest in total mercury determinations because it allows reduction of the well-known problems associated with the inherent risk of contamination, and volatilization and adsorption losses. At present, suitable procedures for on-line pretreatment of solid biological samples are lacking. However, several authors (Tsalev *et al*., 1992a 1992b; Welz *et. al*., 1992; Guo and Baasner, 1993) have demonstrated that microwave digestion coupled with FI-CV-AAS can successfully be applied to the analysis of liquid samples.

3. CONTROL OF CONTAMINATION AND ANALYTE LOSSES

Major difficulties arise due to the mobility and reactivity of mercury and its compounds, respectively, during sample preparation, sample pretreatment, and analysis. Therefore, the stability of samples and standard solutions is of prime importance, and it is advisable to test the stability of typical standard and sample solutions under typical laboratory conditions.
Mercury can disappear from solution due to several mechanisms, including volatilization of mercury compounds, reduction of such compounds followed by volatilization of elemental (metallic) mercury, adsorption on container walls, adsorption onto colloids or particles, incorporation into stable chemical complexes, or incorporation, upon reduction, into stable amalgams.

Thermodynamic considerations of Toribara *et al*. (1970) showed that loss of mercury from a solution containing the element in the monovalent form may occur readily through disproportion and subsequent loss of metallic mercury. Because of the high oxidation potential of the mercury(II)-mercury(I) system, almost any reducing substance could convert some divalent mercury ions into monovalent mercury ions, which then spontaneously disproportion into mercury(II) and mercury(o). The latter escape as metallic vapour from the solution into the gas phase. Because of the almost impossibility of preventing the introduction of small amounts of reducing substances by reagents or solvents, the more dilute mercury(II) solutions would be less stable and lose mercury more readily. The only practical method for stabilizing such solutions is to add a small excess of an oxidising substance (such as permanganate), which has a higher oxidation potential than the mercury(II)-mercury(I) system.
Similarly, Feldman (1974) concluded from his experiments that solutions with 0.1 µg divalent Hg dm-3 in distilled water could be stored in glass vials for as long as five months without deteriorating if the solutions contained 5 % (v/v) HNO3 and 0.01 % Cr2O72-. Storage of such solutions was safe in polyethylene vials for at least 10 days if the solutions contained 5 % (v/v) HNO3 and 0.05 % Cr2O72- . The efficiency of this mixture was probably due to its ability to prevent the hydrolysis of dissolved mercury and prevent its reduction to valencies lower than +2.

4. REDUCING REAGENTS

Tin(II) chloride and sodium tetrahydroborate are predominantly used as reducing reagents for the determination of total mercury by CV-AAS. Sodium tetrahydroborate has been found advantageous for several applications owing to its higher reducing power and faster reaction (Toffaletti and Savory, 1975). In addition, this reductant has been successfully used even in the presence of interfering agents such as iodide and selenium (Kaiser *et al*., 1978). However, potential interferences can occur from metal ions (e.g., Ag(I), Cu(II), Ni(II)), which are themselves reduced to the metallic state and so may occlude mercury through amalgamation.
Welz and Melcher (1984) showed that sodium tetrahydroborate could more readily attack those organic mercury compounds which were not reduced to metallic mercury by tin(II) chloride.

However, they stated that sodium tetrahydroborate could not be recommended as the reducing reagent for the amalgamation technique. They found that, due to the rather violent reaction with sodium tetrahydroborate, fine droplets of the sample solution were carried by the gas stream and contaminated or deactivated the adsorber surface. Further, they considered even more important the fact that not only mercury but all gaseous hydride-forming elements (e.g., arsenic, antimony, selenium) were volatilized when sodium tetrahydroborate was used as reductant. These hydrides reacted with the adsorber material and deactivated its surface, thus no longer permitting a sensitive and reproducible determination of mercury.

5. INTERFERENCES

Interferences by volatile nitrogen oxides in the determination of mercury by FI-CV-AAS were studied by Rokkjaer et al. (1993). The main symptom of the interference effects was a suppression, broadening or even splitting of the mercury signal. The authors postulated that volatile nitrogen oxides formed as reaction products of nitric acid during sample decomposition scavenged the reducing agent and concomitantly inhibited the reduction of mercury(II). The rate of the reaction of nitrogen oxides with the reducing agent was considered to be so fast that it was consumed before the reduction of mercury was complete. Rokkjaer et al. (1993) demonstrated that the interference could easily be remedied by purging the sample solution with an inert gas prior to the introduction of the reducing agent. Lippo et al. (1997) concluded from their experiments that nitrogen mono- and dioxide, having molecular absorption bands at 253.63 nm and 253.85 nm, respectively, might cause unspecific absorption at the specific mercury wavelength of 253.65 nm, leading to enhanced and broadened mercury signals if not properly compensated for by adequate instrumental background correction.

6. INTERNAL (ROUTINE) QUALITY CONTROL

In order to demonstrate that the analytical method applied is fit for the purpose of the investigations to be carried out, control materials should be regularly analysed alongside the test materials (cf. Chapter B.5 of the Manual).

The control materials - preferably certified reference materials (CRM) - should be typical of the test materials under investigation in terms of chemical composition, physical properties and analyte concentration. Fitness for purpose is achieved if the results obtained from the analysis of the control materials are within the defined limits of permissible tolerances in analytical error (see Chapters B.3.5, B.4.2.5 and B.4.2.5.2b of the Manual).

Annex IX:

Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment

REGIONAL SEAS

UNITED NATIONS ENVIRONMENT PROGRAMME **November 2011**

Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment

Recommended Methods For Marine Pollution Studies 71

Prepared in co-operation with

MEDPOL

NOTE: This recommended method is not intended to be an analytical training manual. Therefore, the method is written with the assumption that it will be used by formally trained analytical chemists. Several stages of this procedure are potentially hazardous; users should be familiar with the necessary safety precautions.

For bibliographic purposes this document may be cited as:

UNEP/IAEA: Sample work-up for the analysis of selected chlorinated hydrocarbons in the marine environment. Reference Methods for Marine Pollution Studies No 71, UNEP, 2011.

PREFACE

The Regional Seas Programme was initiated by UNEP in 1974. Since then, the Governing Council of UNEP has repeatedly endorsed a regional approach to the control of marine pollution and the management of marine and coastal resources and has requested the development of regional action plans. The Regional Seas Programme at present includes thirteen regions and has over 140 coastal States participating in it (1).

One of the basic components of the action plans sponsored by UNEP in the framework of the Regional Seas Programme is the assessment of the state of the marine environment, its resources and the sources and trends of the pollution and its impact on human health, marine ecosystems and amenities. In order to assist those participating in this activity and to ensure that the data obtained through this assessment can be compared on a world-wide basis and thus contribute to the Global Environment Monitoring System (GEMS) of UNEP, a set of Reference Methods and Guidelines for marine pollution studies are being developed as part of a programme of comprehensive technical support which includes the provision of expert advice, reference methods and materials, training and data quality assurance (2). The Methods recommended for adoption by Governments participating in the Regional Seas Programme.

The methods and guidelines are prepared in co-operation with the relevant specialised bodies of the United Nations system as well as other organisations and are tested by a number of experts competent in the field relevant to the methods described.

In the description of the methods and guidelines, the style used by the International Organisation for Standardisation (ISO) has been followed as closely as possible.

The methods and guidelines published in UNEP's series of Reference Methods for Marine Pollution Studies are not considered as definitive. They are planned to be periodically revised taking into account the new developments in analytical instrumentation, our understanding of the problems and the actual need of the users. In order to facilitate these revisions, the users are invited to convey their comments and suggestions to:

Marine Environmental Studies Laboratory
IAEA Environment Laboratories
4, Quai Antoine 1er
MC 98000 MONACO

which is responsible for the technical co-ordination of the development, testing and inter-calibration of Reference Methods.

CONTENTS

1. SCOPE AND FIELD OF APPLICATION

This reference method is intended for use in monitoring programmes and pilot research studies. The document describes procedures for the isolation of purified fractions amenable for the determination of DDTs and PCBs in marine sediments and marine organisms by capillary GC/ECD. It is assumed that most of the participants in the UNEP Regional Seas Programmes are equipped with advanced high resolution capillary gas chromatographs and will be able to implement most, if not all, of the procedures described in Reference Method No 40, "Determination of DDTs and PCBs by capillary gas chromatography and electron capture detection" (UNEP 1988). Assuming consistent results are routinely being obtained with these methods by the analytical laboratory, the determination of specific compounds (as opposed to generic mixture of PCBs) opens up the possibility not only of identifying environmental "hot spots", but also for characterising sources, elucidating transport pathways and developing data of greater toxicological relevance. The organisation and content of this document, however, deserves further comment. Under the sections devoted to SEDIMENTS and ORGANISMS, subsections are provided relating to procedures for: 1) Sampling, 2) Extraction and 3) Clean-up and fractionation. In each subsection, several alternative procedures are described. These various procedures have been previously tested and are provided to accommodate the range of capabilities in participating laboratories. For example, laboratories which have access to an HPLC may consider the benefits of using HPLC fractionation procedures in lieu of more conventional low pressure column chromatographic method. Participants are generally encouraged to implement the most effective procedures within the constraints of their individual laboratories.

Several other halogenated pesticides and other electron capturing organic compounds may be present in environmental samples and many of these compounds could also be isolated by the methods described here. However, not all residues will be stable to the clean-up procedures applied for the determination of PCBs and DDTs. Consequently, every analyst must test for analyte recovery and analytical reproducibility prior to applying these methods for other analytes on a routine basis. Primary emphasis should be placed on obtaining the cleanest possible purified fraction for capillary GC/ECD analysis so that interferences and misidentification are minimised, if not eliminated.

2. PRINCIPLES

Following collection of sediment or biota samples using appropriate techniques, samples are stored in trace organic free vessels at -20°C until analysis. For analysis, the samples are prepared for solvent extraction. To achieve a satisfactory recovery of the chlorinated hydrocarbons, samples are dried by either desiccation with anhydrous sodium sulphate or by freeze-drying. Lipids are then Soxhlet extracted from sediments using hexane and dichloromethane, and from biota using hexane or petroleum ether. Following initial clean-up treatments (removal of sulphur from sediment extracts and treatment of biota extracts with concentrated sulphuric acid to destroy some interfering lipids), extracts are fractionated using column chromatography. Detailed protocols for absorption chromatographic fractionation are described for both low and high pressure systems, using Florisil and silica gel respectively. (Additional information concerning alternative techniques including gel permeation chromatography is provided).

3. REAGENTS, SOLVENTS, STANDARDS

3.1. Reagents

3.1.1. List of reagents

- Demineralized distilled water produced by distillation over potassium permanganate (0.1 g/l $KMnO_4$) or equivalent quality, demonstrated to be free from interfering substances.
- Detergent.
- Potassium dichromate.
- HCl. 32%.
- Concentrated H_2SO_4 (d 20°C: 1.84 g/ml).
- Sulfochromic cleaning solution made from concentrated sulphuric acid and potassium

dichromate.
- KOH.
- Anhydrous sodium sulphate.
- Copper fine powder (particle size 63µm).
- Carborundum boiling chips.
- Hg.
- Glass wool
- Alumina (200-240).
- Silica gel (60-100).
- Florisil PR (60-100).
- Bio-Beads SX-3 (200-400).
- Sephadex LX-20.

Solvents:
- Hexane, Dichloromethane, Methanol, Pentane, Cyclohexane, Toluene and Ethyl Acetate, all "distilled in glass" quality.

Standards:
- PCB congeners: 29, 30, 121, 198.
- ε HCH.
- Endosulfan Id_4.
- n-C_{14} d_{30}, n-C_{19} d_{40}, n-C_{32} d_{66}.
- Naphthalene d_8.
- Hexamethylbenzene.
- Cadalene: 1, 6-dimethyl-4-(1-methylethyl)naphthalene.
- DDT reference solutions - Prepare a stock solution of the DDT series (pp' DDT, op DDT, pp' DDD, op DDD, pp' DDE, op DDE) by dissolving 50 mg of each compound in 100 ml of hexane. Store stock solution in sealed glass ampoules.
- Other reference solutions - should be prepared if other residues are to be quantified in these procedures.

NOTES:

Working solutions obtained from the stock reference solutions should be prepared on a regular basis depending on their use and stored in clean glass volumetric flasks tightly capped with non-contaminating materials such as Teflon or glass. Extreme care must be taken to ensure that the concentrations of the standards have not altered due to solvent evaporation.

In order to achieve acceptable accuracy for the standard solutions, at least 50 mg of pure individual compound should be weighed and dissolved into 100 ml of hexane. This will give stock solutions of 500ng/µl.

Example of preparation of stock solutions:

Preparation of a stock solution of pp' DDE at approximately 500ng/µl:

The pp' DDE stock solution is prepared by dissolving approximately (but weighed accurately) 50 mg of pp' DDE in hexane in a 100 ml volumetric flask and bringing the volume to exactly 100 ml with hexane. If the actual weight of pp' DDE is 52 mg, then

$$\frac{52\,\text{mg DDE}}{100\,\text{ml solvent}} \times \frac{1000\,\mu\text{g}}{\text{mg}} \times \frac{\text{ml}}{1000\,\mu\text{l}} = \frac{52\,\text{mg DDE}}{100\,\text{ml of solution}}$$

52 mg/100 ml $\Rightarrow$ 0.52 mg/ml $\Rightarrow$ 520 µg/ml $\Rightarrow$ 520 ng/µl

The concentration of the stock solution will be: 520ng/µl

Preparation of an intermediate solution:

Use the stock solution to prepare the intermediate solution. The concentration of pp' DDE intermediate solution should be approximately 5ng/µl. To prepare the 5ng/µl intermediate solution, transfer 1 ml of the pp' DDE stock solution into a 100 ml volumetric flask and dilute with hexane to 100 ml.

$$\frac{1\,\text{ml DDE stock solution}}{100\,\text{ml final volume}} \times \frac{520\,\text{ng DDE}}{\mu\text{l}} = \frac{5.2\,\text{ng}}{\mu\text{l intermediate solution}}$$

The concentration of the intermediate solution will be: 5.2 ng/µl

Preparation of the working solution:

Use the intermediate solution to prepare the working solution. The concentration of pp' DDE in the working solution could be approximately 50pg/µl.

To prepare the 50 pg/µl working solution, transfer 1 ml of the pp' DDE intermediate solution into a 100 ml volumetric flask and dilute with hexane to 100 ml.

$$\frac{1\,\text{ml DDE intermediate solution}}{100\,\text{ml final volume}} \times \frac{5.2\,\text{ng}}{\mu\text{l}} \times \frac{1000\,\text{pg}}{\text{ng}} = \frac{52\,\text{pg}}{\mu\text{l working solution}}$$

The concentration of the working solution will be: 52 pg/µl

3.1.2. Cleaning of solvents

All reagents, including the distilled water should be of analytical quality. Commercially available solvents like acetone, acetonitrile, dichloromethane, hexane and pentane are invariably contaminated with ECD-active substances; their concentrations vary from batch to batch and with supplier. Reagent quality should be checked by injection of 2 µl of a 100 ml batch of solvent, after concentration to 50 µl in a rotary evaporator. No peak in the GC-ECD chromatogram (90 - 250 °C) should be larger than that for 1pg of lindane. Otherwise, the solvent must be distilled. The following procedure has been found to be both efficient and cost effective, as it allows the use of technical grade solvents as the basic material (reducing the cost by one order of magnitude). 130 - 150 cm height columns are required; the packing material must be glass (to allow subsequent cleaning with an oxidising acid). The entire equipment is cleaned prior to use by 2 consecutive distillation procedures with 500 ml water in each case. It is essential that a current of nitrogen gas (15 ml/min) flows from the distillation flask during distillation of the organic solvents: the condenser serves as exhaust. Ambient air is not in contact with the solvent in this way. Problems are associated with other methods of excluding room air (e.g., active carbon or molecular sieves), the most important one being discontinuity. The condensate is distilled into a 1 litre flask at a 1:20 ratio. This large volume allows for direct transfer into the appropriate solvent containers which should be made of glass and of a sufficient size to provide solvent for not more than 6 analyses. A bottle with sufficient solvent for 10 - 15 analysis has to be opened and closed many times and even when kept closed, when not in use, contamination from the surrounding atmosphere takes place. For more detailed information, consult the Reference Method No 65: UNEP/IOC/IAEA: Reagent and laboratory ware clean-up procedures for low-level contaminant monitoring.

3.1.3. Cleaning of reagents and adsorbents

3.1.3.1. Cleaning of reagents

Powdered or crystalline reagents, such as anhydrous sodium sulfate (Na_2SO_4)*, potassium hydroxide (KOH), glass wool * and carbon or carborundum boiling chips *, must be thoroughly cleaned before use. They should be extracted with hexane in a Soxhlet apparatus for 8 hours and then with methanol or dichloromethane for another 8 hours. For those items indicated by an *, this will require pre-combustion in a muffle furnace at approximately 400°C.

3.1.3.2. Cleaning of adsorbents

Silica gel, alumina and Florisil have to be solvent extracted. Each reagent is first refluxed with methanol or dichloromethane in a Soxhlet apparatus for 8 hours, then with n-hexane for the same period. The solvent is removed by a rotary evaporator operating at low speed, until the sorbent starts falling down as fine particles. Reagents are dried in a drying oven at 0.01 mbar. If this is not available, they are dried in a normal oven at 120°C for 4 hours. This serves to activate silica and alumina. Florisil has to be activated at 130°C for 12 hours. The sorbent is allowed to cool in the oven (if possible under vacuum to avoid uptake of contaminants from the atmosphere) or alternatively, in a dessicator. As active sorbents attract water and contaminants from the atmosphere, controlled deactivation should be carried out by adding water to the fully active sorbent (5% by weight to silica, 2% by weight to alumina, and 0.5% by weight to Florisil). The deactivation procedure should be carried out by adding the water to the sorbent and mixing by gentle shaking for a few minutes. The equilibration takes one day. The activity can be maintained for longer periods of time by sealing the required amount of sorbent in glass ampoules. Otherwise, the activation/deactivation has to be done the day before use.

3.2. Apparatus and equipment

The laboratory used for organic trace analysis must be a dedicated facility, isolated from other projects that could be sources of contamination. It must be properly constructed with fume hoods and benches with electric sockets that are safe for use with flammable solvents. The laboratory must have extractors and rotary evaporators cooling water to run the stills. In tropical regions and in dry climates, a refrigerated re-circulating system should be used to reduce temperatures to the required levels and/or to conserve water. Stainless steel or ceramic tiles make good non-contaminating surfaces. If necessary, benches can be coated with a hard epoxy resin and walls can be painted with epoxy paint. A sheet of aluminium foil on the workbench provides a surface which can be cleaned with solvent. A vented storage facility for solvents is essential. Benches must be fitted with frames to hold stills, extractors, etc. The emergency cut-off switch should be accessible from both inside and outside the laboratory. Fire fighting equipment should be mounted in obvious places and laboratory personnel trained in their use.

3.2.1. List of materials

- A coring device with liners and plunger or a grab sampler (thoroughly cleaned with detergents and solvents before use).
- Glass jars and aluminium foil, stainless steel knives, scoops, forceps, labels, marking pens, logbook.
- Insulated plastic boxes for transporting samples. Ice or dry ice.
- Deep freezer (-18 to -20°C) for sample preservation (frost free type freezers heat to above zero during frost removal cycles and they cannot be used for long term storage).
- Rotary evaporator.
- Kuderna-Danish (or similar) concentrator and heater.
- Soxhlet extraction apparatus and heaters.
- Glassware including boiling flasks, ground glass stoppers, beakers, Erlenmeyer flasks, separatory funnels, centrifuge tubes, weighing bottles, pipettes, tissue grinders.
- Drying oven (temperature range up to at least 300°C) for determining sample dry weights, baking of contaminant residues from glassware and reagents.

Note: A muffle furnace is better for baking materials at greater than 300°C, if required.

- Centrifuge and tubes.
- Freeze-dryer and porcelain pestle and mortar.
- Analytical balance with an accuracy of 0.1 mg and an electro-balance with an accuracy of at least 1 µg.
- Stainless steel tweezers and spatulas.

- Dessicator - completely free of organic contamination and with no grease applied to sealing edges.
- Supply of clean, dry nitrogen.
- Columns for silica gel, alumina and Florisil chromatography.
- Mechanical blender (food mixer).
- Vacuum pump (water-jet air pump).

3.2.2. Cleaning of glassware

Scrub all glassware vigorously with brushes in hot water and detergent. Rinse five times with tap water and twice with distilled water. Rinse with acetone or methanol followed by hexane or petroleum ether. Bake overnight in an oven at 300 °C. All glassware should be stored in dust free cabinets and tightly sealed with pre-cleaned aluminium foil when not in use. Ideally glassware should be cleaned just before use.

For more detailed information, consult Reference Method No 65: UNEP/IOC/IAEA: Reagent and laboratory ware clean-up procedures for low level contaminant monitoring.

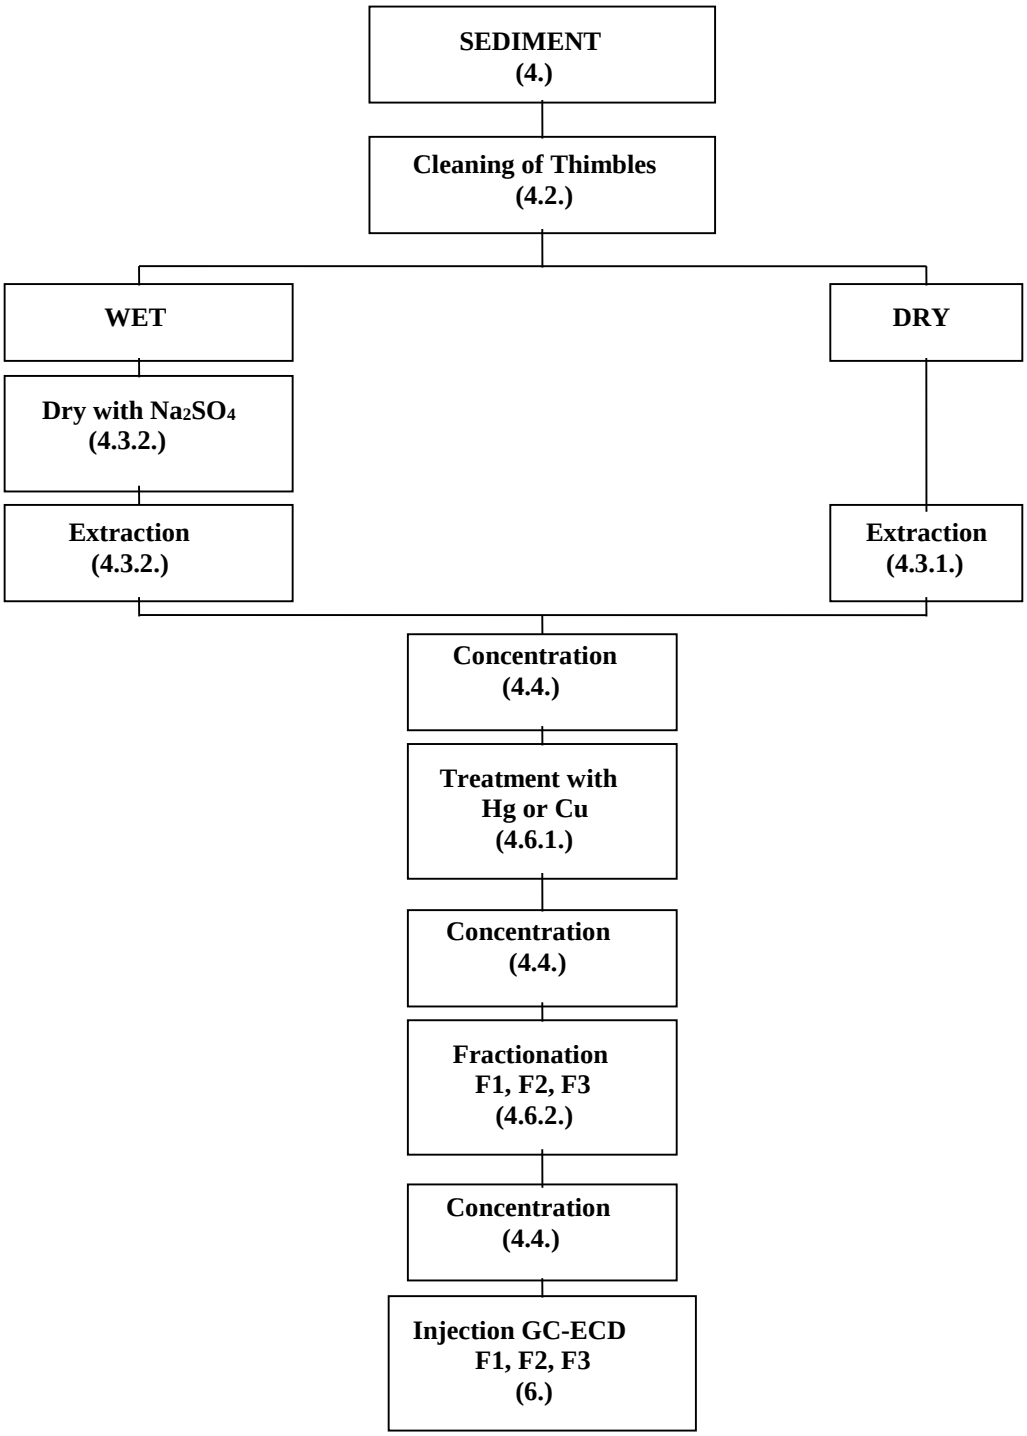

Diagram of the extraction procedure for sediment samples.

4. SEDIMENTS

4.1. Sampling

For the preparation of the samples (including selection of sites, collection of samples and storage) the reader should refer to the Reference Method Nº 58: Guidelines for the use of sediments for the marine pollution monitoring programmes, to the Reference Method Nº 20: UNEP/IOC/IAEA: Monitoring of petroleum hydrocarbons in sediments and to UNEP(DEC)/MEDW.C282/Inf.5/Rev1: Methods for sediment sampling and analysis (2006).

4.2. Cleaning of extraction thimbles

Paper extraction thimbles should be cleaned prior to sample extraction. For use in the extraction of sediment samples, the extraction can be performed in the Soxhlet apparatus with 250 ml of a mixture hexane / dichloromethane (50:50) for 8 hours cycling the solvent through at a rate of 4 to 5 cycles per hour. Add into the solvent a few carborundum boiling chips to get a regular ebullition.

The use of disposable paper thimbles for the extraction procedure rather than re-usable glass fibre thimbles is recommended due to the difficulties encountered in cleaning the latter.

4.3. Extraction of sediments

4.3.1. Extraction of freeze-dried samples

Select a 50-100 g sub-sample of the sediment, weigh this sub-sample and freeze-dry it. When dried, re-weigh it and calculate the dry to wet ratio. Then pulverise the sample using a pestle and mortar and sieve it using a 250 µm stainless steel sieve. Accurately weigh about 20 g of ground sample and place it in the pre-cleaned extraction thimble. Add 1 ml of a solution of 25 pg/µl of 2,4,5 trichlorobiphenyl (PCB Nº 29), 20.9 pg/µl of 2,2',3,3',4,5,5',6 octachlorobiphenyl (PCB Nº 198), 20 pg/µl of ε HCH and 21 pg/µl of Endosulfan Id_4 as internal standards and extract for 8 hours in a Soxhlet apparatus with 250 ml of a mixture hexane / dichloromethane (50:50), cycling the solvent through at a rate of 4 to 5 cycles per hour, add into the solvent a few carborundum boiling chips to get a regular ebullition. Alternatively (or in addition), PCB congeners No 30, 121, or octachloronaphthalene and PCB congeners can be used as internal standards. Prepare a procedural blank by extracting an empty thimble using the same procedure as for the samples.

4.3.2. Extraction of wet samples

The sediment is thawed, sieved at 250 µm and homogenised manually with a stainless steel spatula or clean glass rod. A sub-sample of 1-2 g is weighed into a flask and placed in a drying oven at 105 °C for 24 hours, then allowed to cool to room temperature and re-weighed. Calculate the dry to wet ratio and discard the dry sediment (unless it is being used for other analysis e.g. TOC, total organic carbon).

Place a 30-40 g sub-sample of thawed, homogenised sediment into a blender. Slowly, add 100g of anhydrous sodium sulphate (desiccant) and blend the mixture at high speed for 10 minutes. Transfer the dried sample quantitatively to the pre-cleaned extraction thimble in the Soxhlet apparatus, add the internal standard solution (see above) and apply the same extraction procedure as above. Extract the same amount of sodium sulphate as a procedural blank, making sure to add an appropriate amount of internal standard solution.

4.3.3. Example of determination of percent moisture

Many environmental measurements require the results to be reported on a dry weight basis. The percent moisture or water content in the sample is determined by weighing an aliquot, not used for analysis, of the sample before and after drying. The drying can be done by heating a few grams (1-2 g) of the sample in an oven to constant weight.

Weigh an empty glass beaker that will be used to hold the sample while it is dried.
Empty beaker weight = 10.4417 g

Add the wet sample to the beaker and reweigh. Calculate the wet weight of the sample.
Empty beaker weight + wet sample = 12.2972 g
Wet sample weight = 12.2972 g - 10.4417 g = 1.8555 g

Dry the sample to constant weight: dry the sample for 24 hours, weigh it, dry again for 12 hours, re-weigh it, when the difference in weight is less than 5%, it means that the sample is dried.
Empty beaker weight + dry sample weight = 10.9396 g
Dry sample weight = 10.9396 g - Empty beaker weight
Dry sample weight = 10.9396 g - 10.4417 g = 0.4979 g

Calculate the percent dry sample weight.

$$\% \text{ Sample weight} = \frac{\text{Sample dry weight}}{\text{Sample wet weight}} \text{ X } 100$$

$$= \frac{0.4979}{1.8555} \text{ X } 100 = 26.8 \%$$

Calculate the percent moisture.

Water content = wet weight - dry weight
= 1.855 g - 0.4979 g = 1.3576 g

$$\% \text{ Moisture} = \frac{\text{Sample water weight}}{\text{Sample wet weight}} \text{ X } 100$$

$$\% \text{ moisture} = \frac{1.3576}{1.8555} \text{ X } 100 = 73.2 \%$$

4.4. Concentration of the extract

For both extraction procedures, the extracts are concentrated in a rotary evaporator to about 15 ml. Under good vacuum conditions the temperature of the water bath must not exceed 30 °C. Dry the extract with anhydrous sodium sulphate (when the sodium sulphate moves freely in the flask it means that the extract is dried). Collect the dried extract in the graduated tube of a Kuderna-Danish concentrator. Concentrate the extract to approximately 5 ml with the Kuderna-Danish concentrator and adjust the volume to exactly 1 ml by evaporating excess solvent under a gentle stream of clean dry nitrogen. The sample extract will be analysed gravimetrically for extractable organic matter (EOM) content at the 1 ml volume as a starting point. If measurements of the EOM are outside the calibration range of the balance, the total volume of the extract is adjusted accordingly using either dilution with hexane or evaporating under a stream of nitrogen gas.

4.5. Extractable organic matter

Before carrying out the clean-up procedure, it is advisable to determine the extractable organic matter.

The EOM is determined in the following manner. On the weighing pan of an electro-balance, evaporate a known volume of the sediment or biota extract (up to 100 µl) and weigh the residue with a precision of about ± 1 µg. If the residue is less than 2 µg, pre-concentration of the original extract is required. The quantity of EOM is:

$$\text{EOM (µg/g)} = \frac{\text{Weight of residue (µg) x volume of the extract (ml) x 1000}}{\text{Volume evaporated (µl) x quantity of sample extracted (g)}}$$

Note that extreme care must be taken to ensure balance and pans are clean, dry and stable to obtain accurate readings at the ± 1 µg level. A small hot plate is used to warm pans and forceps and thus keep these instruments dry after solvent cleaning. If no electro-balance is available, a known volume of the extract can be transferred into a clean pre-weighed beaker. The solvent is evaporated with dry and clean nitrogen until a constant weight of about 1 mg is reached. Calculate the amount of "lipids" in the sample taking into account the volume of the lipid extract which was dried.

Example of calculation of E.O.M.

The extractable organic matter content of a sample is operationally defined as the weight of material extracted with the solvent employed (H.E.O.M. in case hexane is used as solvent). An aliquot of the sample extract is taken (few µl), the solvent is evaporated and the residue is weighed to determine the quantity of lipids extracted in the aliquot and from it to the total sample. The results are normally reported in mg lipids per gram dry weight extracted.

A 1 µl aliquot is removed from a 2.5 ml sample extract for determination of E.O.M. The 1 µl aliquot is evaporated on the pan of an electro-balance and the residue is weighed. Three determinations are made and the average taken.

Measurements:
Sample dry weight extracted: 4.443 g
Total volume of the extract: 2.5 ml
Sample aliquot removed: 1 µl
(1) Weight of a 1 µl aliquot after solvent evaporation: 32.2 µg
(2) Weight of a 1 µl aliquot after solvent evaporation: 32.1 µg
(3) Weight of a 1 µl aliquot after solvent evaporation: 32.3 µg
Average weight of a 1 µl aliquot : 32.2 µg

Total volume of the extract: 2.5 ml

Total quantity of lipids in the sample:

$$32.2\ \text{µg/µl} \times 2.5\ \text{ml} \times \frac{1000\ \text{µl}}{\text{ml}} = 80500\ \text{µg or: } 80.5\ \text{mg}$$

With 4.443 g of sample extracted:
80.5 mg/ 4.443 g = 18.1 mg lipids/g

4.6. Clean-up procedure and fractionation

Purposes of the clean-up: removal of lipids, whenever present at a significant amount; removal of elementary sulphur and sulphur compounds. Both these compound classes can interfere with the gas-chromatographic separation.

4.6.1. Sulphur and sulphur compounds removal

Elementary sulphur and sulphur compounds such as mercaptans should be removed from the extract. This could be done by using either mercury or activated copper.

a) Mercury method.

Add one drop (a few ml) of mercury to the sediment extract and shake vigorously for one minute. Centrifuge and carefully recover and transfer the extract in another tube with a Pasteur pipette. If the mercury is still tarnished, repeat the treatment with another drop of mercury, shake, transfer the hexane into another tube. Repeat this treatment until the mercury stays brilliant in the extract. Rinse the mercury with 5 ml of hexane and combine the extracts. Then, concentrate the resulting solution to ca. 1 ml with a gentle stream of nitrogen.

Cleaning of mercury:

Caution: When removing mercury from the sample, always use a plastic tray to keep the glassware in and work under a fume hood.

Fit a folded filter paper in a 10 cm diameter conical glass funnel and fix the funnel over a 250 ml glass beaker. Using a needle, make a small hole in the bottom of the filter paper. Carefully put the mercury onto the funnel. The mercury flows through the small hole in the filter paper leaving the solid impurities on its surface. The mercury collected is washed three times by shaking it carefully with dichloromethane and by removing dichloromethane layer with the help of a clean glass syringe. Allow the rest of dichloromethane evaporate and store the clean mercury in a thick walled glass bottle with a ground glass stopper. In order to avoid escape of mercury vapour, store the mercury under methanol.

Another way of cleaning the mercury involves sucking the dirty mercury through a capillary tube, such as a Pasteur pipette, connected to a guard-flask and then to a vacuum pump. The mercury will pass through the Pasteur pipette and will be collected and cleaned in the guard-flask. Then it should be transferred into a thick wall glass bottle with a ground glass stopper. The mercury is covered with a layer of methanol to protect it from oxidation.

b) Activated copper method.

Transfer about 20 grams of the copper powder in an Erlenmeyer. Add enough concentrated HCl to cover the copper powder, agitate. Sonicate for 10 min., agitate, put again in ultrasonic bath and sonicate for 10 min. Throw the used HCl, add some fresh HCl, transfer in ultrasonic bath and sonicate for 20 min. repeat that procedure four times in total. Wash with distilled water, agitate, discard, add water again, transfer in ultrasonic bath and sonicate for 15 min., discard the used water, repeat that procedure again, up to pH neutral. Wash with acetone, agitate, transfer in ultrasonic bath and sonicate for 15 min. repeat that procedure four times in total. Then use the same procedure with hexane as a solvent.
Keep in hexane (use it immediately, avoids Cu to be in contact with air).

Transfer 3 to 4 Pasteur pipettes per sample in the flasks containing the hexane extracts. Let the copper react all night. The presence of sulphur compounds in the sample will be detected by the tarnishing of the copper powder. Then, concentrate the resulting solution to ca. 1 ml with a gentle stream of pure nitrogen.

4.6.2. Fractionation

An adsorption chromatography step is used to remove interfering lipids and to fractionate the extract into classes of compounds. Many variations of adsorption chromatography clean-up procedures have been published to date. Four procedures are reported here in order of increasing complexity.

Preparation of the columns: Glass burettes (1 cm diameter) with Teflon stopcocks make convenient adsorption columns. The column is plugged with pre-cleaned cotton or glass wool. Prepare separate columns for each sample and blank determination. The column is partially filled with hexane. The appropriate amount of sorbent is mixed with hexane in a small beaker to form a slurry. A glass funnel and a glass rod are used to pour the adsorbent into the column. Several rinses with hexane are necessary to fill the column to the desired height. Tap with a pencil or a hard silicone tube against the column in order to settle the adsorbent into an even bed. Flush the material adhering to the wall of the column down to the bed with solvent. Prepare each column freshly immediately before use. Never let the column get dry.

4.6.2.1. Florisil

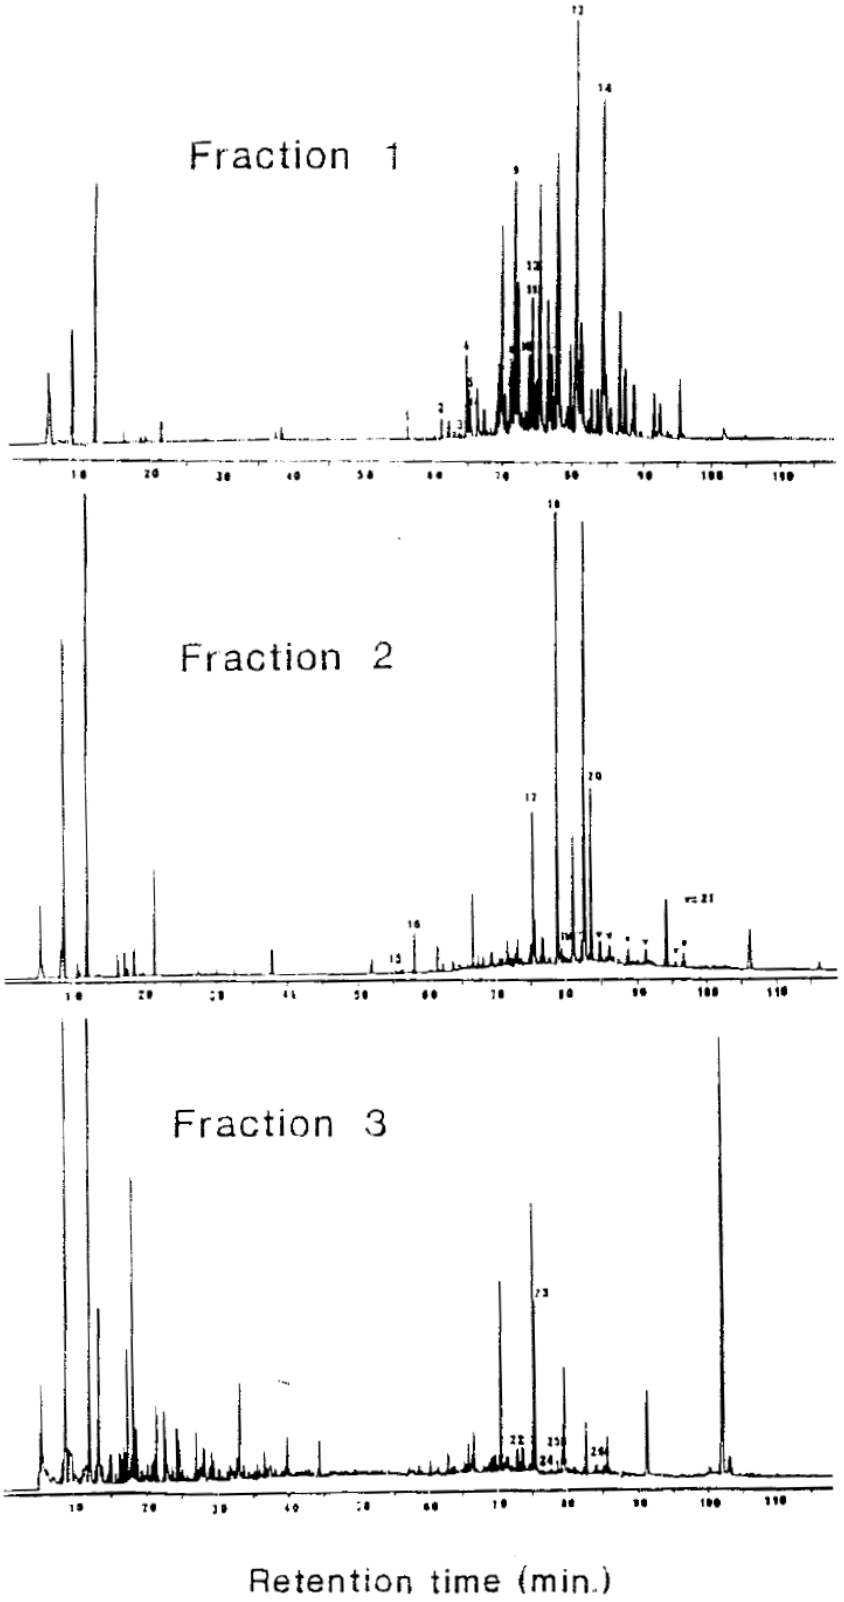
A Florisil column is used for this fractionation, which is prepared in the following way. The Florisil should be pre-extracted in the Soxhlet apparatus to remove any contaminants, using methanol or dichloromethane for 8 hours, followed by hexane for another 8 hours. It is then dried in an oven. Activation is achieved by heating the dried Florisil at 130°C for 12 hours. It is then partially deactivated with 0.5% water by weight and stored in a tightly sealed glass jar with ground glass stopper. The water should be well mixed into the Florisil and the mixture should be allowed to equilibrate for one day before use. The activation/deactivation procedure should be carried out one day before use. A 1 cm burette with Teflon stopcock is plugged with pre-cleaned glass wool. A column with a sintered glass disk could also be used. 17 grams of Florisil are weighed out in a beaker and covered with hexane. A slurry is made by agitation and poured into the glass column. The Florisil is allowed to settle into an even bed and any Florisil adhering to the column is rinsed down with hexane. The solvent is drained to just above the Florisil bed. It should be rinsed with a further 5 ml of hexane; one gram of anhydrous sodium sulphate is added to the top of the column in order to protect the surface of the Florisil from any disturbance. The column should never run dry. Individual columns should be prepared immediately before use and a new column of Florisil used for each sample.

The extract, reduced to 1 ml, is put onto the Florisil column. It is carefully eluted with 65 ml of hexane and the first fraction collected. Then the column is eluted with 45 ml of a mixture containing 70 % of hexane and 30 % of dichloromethane and the second fraction collected. The third fraction will be eluted with 60 ml of pure dichloromethane.

Fraction one will contain the PCBs, pp’ and op DDE and some other pesticides such as HCB, aldrin, heptachlor, DDMU.

Fraction two will contain the DDTs, DDDs, most of the toxaphene, and some pesticides such as the HCH isomers and chlordane components.

Fraction three will contain mainly dieldrin, endrin, heptachlor epoxide and endosulfan components. Typical chromatograms obtained are shown below.



Peak Number	Compounds
1	H.C.B
2	Internal Standard 2, 4, 5 trichlorobiphenyl (IUPAC No : 29)
3	Heptachlor
4	2,2',5,5' tetrachlorobiphenyl (IUPAC No : 52)
5	2,2',4,5' tetrachlorobiphenyl (IUPAC No : 49)
6	Aldrin
7	DDMU
8	op DDE
9	2,2',4,5,5'pentachlorobiphenyl (IUPAC No : 101)
10	2,2',3',4,5 pentachlorobiphenyl (IUPAC No : 97)
11	pp' DDE
12	2,2',3,3',6,6' hexachlorobiphenyl (IUPAC No : 136)
13	2,2',4,4',5,5' hexachlorobiphenyl (IUPAC No : 153)
14	2,2',3,4,4',5' hexachlorobiphenyl (IUPAC No : 138)
15	Alpha-HCH
16	Lindane
17	op DDD
18	pp' DDD
19	op DDT
20	pp' DDT
21	Toxaphene
22	Alpha-endosulfan
23	Dieldrin
24	Endrin
25	Beta-endosulfan
26	Endosulfan sulfate

Figure 2: GC-ECD organohalogen analyses

4.6.2.2. Gel permeation chromatography

Low pressure GPC can be used as an alternative clean-up technique to remove high molecular weight co-extractable lipidic material from polycyclic aromatic compounds and halogenated aromatics. Concurrently, elemental sulphur could be also removed from the whole organic extract.

The main feature of the semi-preparative-GPC as a clean-up technique relies on the compatibility of this analytical procedure with labile components of the extract (i.e. DDTs, chlorinated cyclohexadiene derivatives), which are not stable in other types of extract clean-up procedures. Further, GPC as a clean-up technique has already been automated, enabling a high sample throughput, taking into account the short analysis time involved.

The GPC retention mechanism may involve adsorption, partition and size exclusion mechanisms. The predominance of one mechanism over the others is largely determined by the choice of the mobile phase and the pore size of the packing. In the case of GPC packings with large pore size (1000-2000 daltons) size exclusion and adsorption mechanisms prevail (Bio-Beads SX-3 using cyclohexane, dichloromethane-hexane, dichloromethane-cyclohexane, toluene-ethylacetate and ethylacetate-cyclohexane) (Ericksson *et al*., 1986). On the other hand, when smaller pore sizes (400 daltons) are used in combination with highly polar solvents, (THF, DMF) size exclusion predominates (Lee *et al*., 1981). While using the first approach, a chemical class fractionation could be obtained, however, if smaller pore sizes are used it should be combined with another fractionation technique (i.e. adsorption chromatography) to achieve this selectivity. It has yet to be demonstrated that using GPC as a single clean-up step produces a completely clean extract for GC-ECD determination. Nevertheless, taking into account the increasing availability of high-resolution low molecular weight exclusion packings, they could definitively integrate fractionation and clean-up in a single step.

Low resolution packing (Sephadex LH and Bio-Beads SX, 200-400 mesh size) are the most widely used because they are inexpensive and afford relatively high sample loading (500 mg in 10 mm i.d. columns). The implementation of low resolution GPC requires a solvent delivery system and a UV detector and may be useful. For method development, it is advisable to inject a broad range of standard compounds covering the whole range of molecular weights of the analytes to be determined in order to determine the cut-off points to fractionate real samples. Reported recoveries of PCBs and PAHs range from 60 to 80 % for the concentration level (ng) injected. (Fernandez and Bayona, 1992).

4.6.2.3. Alumina and HPLC (silica column)

The first step in this clean-up procedure is an adsorption step using an alumina column to remove most of the lipid material. Prepare an alumina column (4 x 0.5 cm i.d., made from a Pasteur pipette). Apply the concentrated extract to the top of the column and elute with 10 ml hexane. Concentrate the eluate to about 200 µl. It is followed by a second step to more completely remove interfering compounds and at the same time to separate the compounds of interest into different fractions, containing aliphatics, PCBs, PAHs, pesticides and toxaphene. Between 20 and 200 µl of the extract (after alumina clean-up) are eluted on a stainless steel column (200 x 4 mm i.d.), packed with Nucleosil 100-5 with n-pentane, 20 % dichloromethane in n-pentane and finally dichloromethane. The eluate is collected in fractions containing 1) n-hydrocarbons, 2) PCBs, 3) PAHs and toxaphene, 4) pesticides and toxaphene and 5) acids, etc. (polar compounds). The size of the fractions has to be determined with standard solutions containing the compounds of interest, collecting the eluate in 0.5 ml fractions. Each fraction is then analysed by GC-ECD. Full details have been given in the literature (Petrick *et al*., 1988 and IOC, 1993).

4.6.2.4. High pressure chromatography

High pressure liquid chromatography (HPLC) columns packed with microparticles are available and have the advantages of high reproducibility, low consumption of solvents, high efficiency and high sample loading capacity.

This method can be used to separate fractions containing aliphatic hydrocarbons, PCBs and aromatic hydrocarbons from interfering compounds. These fractions can then be analysed separately for their constituents by GC-FID and/or GC-ECD.

HPLC methods have been developed using synthetic solutions of n-alkanes, PAHs, pesticides, PCBs and toxaphene and have been applied to samples in which interfering substances were present in such high concentrations as to render the analysis of HC and PCBs extremely difficult without this clean-up procedure (e.g. sediments and biological tissues with OCs in the ng/g range). The samples are eluted with n-hexane, subjected to clean-up over alumina, concentrated down to 20-200 µl and treated by HPLC. With the use of n-hexane, n-pentane and 10 %, 20 % and 50 % dichloromethane in n-hexane, respectively, the following five fractions are obtained : 1) n-hydrocarbons and alkenes, 2) PCBs and alkylbenzenes, 3) PAHs and toxaphene, 4) pesticides, 5) acids, etc.(polar compounds). (Petrick *et al*. 1988).

5. BIOTA

5.1. Sampling

Organisms accumulate many contaminants from their environment (i.e., from sea water, suspended particulate matter, sediment and food). Field and laboratory studies have shown that contaminant concentrations in some marine plants and animals reflect concentrations in their environment. Scientists use this process (termed bio-accumulation) to assess marine contamination resulting from human activity (e.g., pipeline discharges, dumping from ships).

There are problems with using biota as bio-accumulators (bio-indicators). For example, tissues from individuals of a species exposed to the same contaminant concentration may contain different levels of contamination after the same exposure time. These deviations reflect individual differences in factors such as age, sex, size, and physiological and nutritional states. Also, various species show different contaminant concentrations following identical exposure; differences in elimination rates may partially account for this. These factors must be considered when planning a monitoring programme in order to control their effects on the precision of the analysis (by reducing the variances). Variance reduction is necessary in order to detect smaller differences in mean contaminant concentrations observed in monitoring programmes.

For proper sampling and sample preparation, refer to Reference Method No 6 “Guidelines for monitoring chemical contaminants in the sea using marine organisms” and Reference Method No 12 Rev.2 “ Sampling of selected marine organisms and sample preparation for the analysis of chlorinated hydrocarbons”.

5.2. Cleaning of extraction thimbles

As for extraction of sediment samples, thimbles should be extracted first with the same solvent used for the extraction of the sample. As the extraction of biota sample is achieved with hexane, a pre-extraction of these thimbles is made with 250 ml of hexane for 8 hours in the Soxhlet apparatus, cycling the solvent through at a rate of 4 to 5 cycles per hour. Add into the solvent a few carborundum boiling chips to get a regular ebullition.

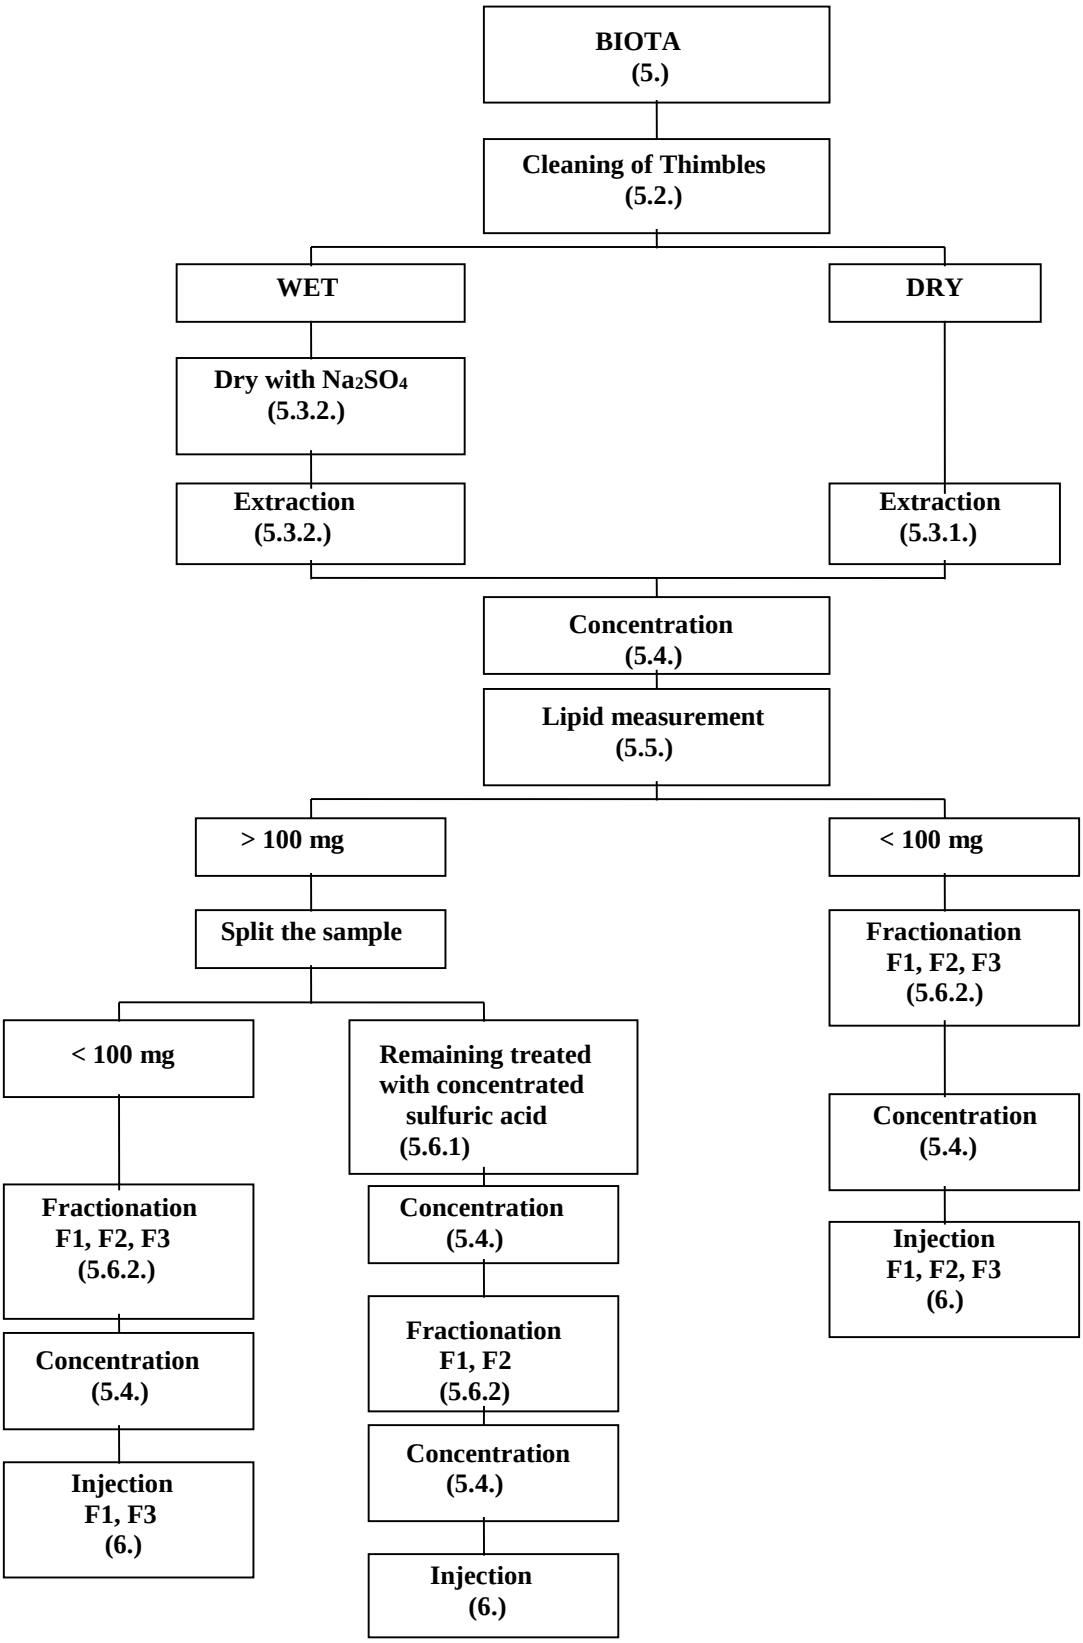


Figure 3: Diagram of the extraction procedure for biota samples.

5.3. Extraction of tissues

5.3.1. Extraction procedure for freeze-dried samples.

Take a 50 to 100 g fresh weight sub-sample from the sample. Weigh this sub-sample and freeze-dry it. When the sub-sample appears to be dry, re-weigh it and freeze-dry it for a further 24 hours and then re-weigh it. If the difference between the two dry weights is greater than 5%, continue the freeze-drying process. Special care must be taken to ensure that the freeze-drier is clean and does not contaminate the samples. The freeze drying procedure should be tested by drying 100 g Na_2SO_4 as a blank and extracting this as a sample. Pulverise the freeze-dried sub-sample carefully using a cleaned pestle and mortar. Accurately weigh about 5 to 10 g of this pulverised material, note the exact weight to be extracted, and place it into a pre-cleaned extraction thimble in a Soxhlet apparatus. The size of the sub-sample should be adjusted so that about 100 mg of extractable organic matter ("lipid") will be obtained. Smaller sub-samples should be used if residue concentrations are expected to be high. Add a known amount of internal standard to the sub-sample in the thimble before Soxhlet extraction. It is important to spike the sample at levels that are near to that of the analyte concentrations in the samples. If, in the end, the analyte and the internal standard concentrations do not fall within the established calibration range of the GC-ECD, the analysis must be repeated. Consequently, it may be advisable to perform range-finding analysis for samples of unknown character beforehand. Candidate internal standards are the same as for sediment samples (see 5.3.). Add about 200 ml of hexane or petroleum ether to the extraction flask with a few carborundum boiling chips, and extract the sample for 8 hours cycling the solvent through at a rate of 4 to 5 cycles per hour. Extract an empty thimble as a procedural blank, making sure to spike it with internal standards in the same fashion as the sample. If unacceptable procedural blanks are found, the source of contamination must be identified and eliminated rather than subtracting high blank values from the analytical results.

5.3.2. Extraction procedure without freeze-drying

Select a 25 to 100 g fresh weight sub-sample and place in a blender. Add anhydrous sodium sulphate to the sample, manually homogenise and determine whether the sample is adequately dried. If not, more sodium sulphate should be added until a dry mixture is obtained. Normally, 3 times by the sample weight used should be enough. Once this has been achieved, blend the mixture at high speed for 1 or 2 minutes until the mixture is well homogenised and the sample appears to be dry. Transfer the mixture to a pre-cleaned extraction thimble, add internal standards as described above and extract the dehydrated tissue with about 200 ml hexane or petroleum ether for 8 hours in a Soxhlet apparatus, cycling 4 to 5 times per hour. Extract the same amount of sodium sulphate as the procedural blank, making sure to add internal standards in the same fashion as the sample.

5.4. Concentration of the extract

Refer to section (4.4.)

5.5. Extractable Organic Matter (EOM)

Refer to section (4.5.)

5.6. Clean-up procedure and fractionation

5.6.1. Removal of lipids by concentrated sulphuric acid

If the lipid content of the extracts is higher than 100-150 mg, a preliminary step for the removal of the lipids is necessary before further sample purification. This can be carried out by using concentrated sulphuric acid. Treatment with sulphuric acid is used when chlorinated hydrocarbons are to be determined. However, sulphuric acid will destroy dieldrin and endrin so that an aliquot of the untreated extract must be set aside for the determination of these compounds.
CAUTION: During all this procedure it is very important to wear safety glasses.

Take an aliquot of the concentrated extract, containing about 200 mg of "lipids", transfer into a separatory funnel and add to this extract enough hexane in order to dilute the sample (40 to 50 ml should be enough), this will allow recovery of the hexane after acid treatment, because if the sample is too concentrated, the destroyed "lipids" will become almost solid and it will be difficult then to recover the hexane from this solid mass. Add 5 ml concentrated sulphuric acid to the extract and tightly fit the glass stopper and shake vigorously. Invert the funnel and carefully vent the vapours out through the stopcock. Repeat this procedure for several minutes. Place the separatory funnel in a rack and allow the phases to separate. Four or five samples and a spiked blank are convenient to process at one time. The extract should be colourless. Recover the hexane phase into a glass beaker. Dry with sodium sulphate and transfer the hexane into a Kuderna-Danish concentrator. Reduce the volume of the extract by evaporating the solvent with a gentle stream of pure nitrogen to about 1 ml.

5.6.2. Fractionation

Refer to section (4.6.2.)

6. CAPILLARY GAS CHROMATOGRAPHIC DETERMINATIONS

6.1. Gas chromatographic conditions

- Gas chromatograph with a split/splitless injection system, separate regulation system for inlet and column pressures and temperatures; multi-ramp temperature programming facilities (preferably microprocessor controlled), electron capture detector interfaced with the column with electronic control unit and pulsed mode facilities. An integrator with a short response time (0.25 s) is essential.

- Narrow-bore (0.22 mm internal diameter), 25 m long, fused silica open tubular column, coated with SE-54 (0.17 µm film thickness, preferably chemically bonded) with sufficient resolution to separate the relevant peaks in the standards provided for PCB analysis.

- Carrier gas should be high purity H_2. If this is not available or if the GC is not equipped with a special security system for hydrogen leak, He may be used. Gas purification traps should be used with molecular sieves to remove oxygen, moisture and other interfering substances.

- High purity nitrogen gas (99.995 %) as ECD make-up gas can be used (Argon/methane high purity gas is another option).

Conditions:

- H_2 or He carrier gas at inlet pressure of 0.5 to 1 Kg/cm^2 to achieve a flow rate of 1 to 2 ml/min.

- Make-up gas N_2 or Ar/CH_4 at the flow rate recommended by the manufacturer (between 30 and 60 ml/min.).

- ECD temperature: 300°C

6.2. Column preparation

Fused silica columns are the columns of choice for their inertness and durability (they are extremely flexible). They are made of material that is stable up to 360 °C. The 5 % phenyl methyl silicone gum (SE-54) liquid phase, is present as a thin, (0.17 µm), uniform film which can tolerate temperatures up to 300 °C. SE-54 is relatively resistant to the detrimental effects of solvents, oxygen and water, at least at low temperatures. These columns are even more resistant and durable if the liquid phase is chemically bonded to the support by the manufacturer.

For GC/MS work, it is advised to restrict the film thickness to 0.17 µm because with thicker films some of the phase could be released, resulting in an increase of the noise signal in the GC/MS.

The flexible fused silica columns can be conveniently connected directly to the inlet and outlet systems without the transfer lines used in conventional glass capillary chromatography which often lead to increased dead volume. Low bleed graphite or vespel ferrules provide a good seal.

The presence of extraneous peaks and elevated baseline drift will result in poor detector performance. This can be caused by components which elute from the column, such as residual solvents and low molecular weight liquid phase fractions on new columns and build-up of later eluting compounds on old columns. Conditioning is a necessary step to remove these contaminants. New columns are connected to the inlet (while left unconnected to the detector). Columns are flushed with carrier gas at low temperature for 15 min. to remove the oxygen, then heated at 70-100 °C for 30 min. and finally at 170 °C overnight. The column can be then connected to the detector. Old columns can be heated directly to elevated temperatures overnight. The final temperature is selected as a compromise between time required to develop a stable baseline and expected column life. Thus, it may be necessary for older columns to be heated to the maximum temperature of the liquid phase resulting in shorter column life. The temperature of the ECD, when connected to the column, should always be at least 50 °C higher than the column, in order to avoid condensation of the material onto the detector foil. It is essential that carrier gas flows through the column at all times when at elevated temperatures. Even short exposure of the column to higher temperature without sufficient flow will ruin the column.

CAUTION: if H_2 is used as a carrier gas, position the column end outside of the oven to avoid explosion risk.

6.3. Column test

When the column has been connected to the detector, the carrier gas flow is set to 30 ml per minute for a column with 4 mm internal diameter. The column performance is then measured according to the criteria of the "number of theoretical plates" for a specific compound and can be achieved according to the following procedure.

- Set injector and detector temperatures at 200 and 300°C respectively and the column oven temperature at 180 °C.
- Inject pp' DDT standard and measure the retention time (Tr). Adjust the column temperature to get a pp' DDT retention time relative to Aldrin of 3.03.
- Measure the width of the pp' DDT peak at its half height ($b_{1/2}$), in minutes and the retention time (Tr) also in minutes.
- Calculate the number of theoretical plates using the formula:

$$N = 5.54\left(\frac{Tr}{b_{1/2}}\right)^2$$

- A parameter which is independent of the column length is the height equivalent to a theoretical plate (HETP):

$$HEPT = \frac{L}{N}$$

Where L is the column length. Adjust the flow rate of the carrier gas to obtain optimum performance. The HETP should be as low as possible (i.e. the number of theoretical plates should be as great as possible).

The column remains in optimum condition as long as the liquid phase exists as a thin, uniform film. The quality of the film at the inlet side may be degraded as a result of repeated splitless

injections. Decreased column quality may be remedied by the removal of the end of the column (10 to 20 cm) at the inlet side. Chemically bonded liquid phases require less maintenance.

6.4. Electron capture detector

High-energy electrons, emitted by a radioactive source within the detector (e.g. a ^{63}Ni foil), are subject to repeated collisions with carrier gas molecules, producing secondary electrons. These electrons, upon returning to their normal state, can be captured by sample molecules, eluting from a GC column. The resulting reduction in cell current is the operating principle of an electron capture detector. The detector current produced is actually a non-linear function of the concentration of electron-capturing material. However, the useful linear range of an ECD may be greatly improved if the instrument is operated at a constant current, but in a pulsed mode, i.e. with short voltage pulses being applied to the cell electrodes. The current in the cell is kept constant by varying the frequency of the pulses.

Contamination of the detector (and thus lower sensitivity) may result from high-boiling organic compounds eluting from the column. Periodic heating to 350°C may overcome this problem. The ^{63}Ni ECD can be used at 320°C under normal operational conditions, in order to limit such contamination.

The optimum flow for an ECD (30 to 60 ml/min.) is much higher than carrier gas flow through the column of one or two ml/min. Thus an additional detector purge flow is necessary (N_2 or Ar/CH_4). Once leaving the outlet of the column, the compounds have to be taken up into an increased gas flow in order to avoid extra-volume band broadening within the detector. Thus, the detector purge flow also serves as the sweep gas.

6.5. Quantification

The most widely used information for identification of a peak is its retention time, or its relative retention time (i.e., the adjusted retention time relative to that of a selected reference compound). Retention behaviour is temperature dependent and comparison of retention times obtained at two or more temperatures may aid in determining a peak's identity. However, retention times are not specific and despite the high resolution offered by capillary columns, two compounds of interest in the same sample may have identical retention times.

One way of using retention indexes could be to inject di-n-alkyl-phthalates such as a mixture containing di-n-methyl-phthalate, di-n-ethyl-phthalate, di-n-propyl-phthalate, di-n-butyl-phthalate, di-n-hexyl-phthalate and di-n-heptyl-phthalate, which will cover the elution range from 70°C to 260°C. An arbitrary index of 100 is given to the di-n-methyl phthalate, 200 to the di-n-ethyl phthalate, and so on up to 700 to the di-n-heptyl phthalate; it is possible to identify all chlorinated pesticides by a proper retention index. This will be used also for unknown compounds which can be found easily on the GC/MS using the same index and so, identified. (Villeneuve J.P. 1986).

PCBs represent a complex mixture of compounds that cannot all be resolved on a packed column. Also there is no simple standard available for their quantification. Each peak in a sample chromatogram might correspond to a mixture of more than one individual compound. These difficulties have led to the recommendation of various quantification procedures. The usual method to quantify PCBs is to compare packed-column chromatograms of commercially available industrial formulations (Aroclors, Clophens, Phenoclors) with the sample chromatogram. Most commonly, it is possible to match one single formulation, such as Aroclor 1254 or Aroclor 1260 with the sample chromatogram. An industrial formulation (or mixture of formulations) should be chosen to be as close a match as possible and in the case of sample extracts from sediment or organisms, Aroclor 1254 and Aroclor 1260 are most frequently chosen.

For the second fraction obtained on Florisil separation, it is possible to quantify DDTs after comparison with the retention times of peaks in the sample chromatogram to those in the corresponding standard, the peak heights (or peak areas) are measured and related to the peak height (or peak area) in the standard according to the formula:

$$[\text{Concentration}] = \frac{h \times C \times V \times 1000}{h' \times V(\text{inj}) \times M \times R} \text{ ng/g (or pg/g)}$$

Where:

V = total extract volume (ml)
M = weight of sample extracted (g)
H = peak height of the compound in the sample
h' = peak height of the compound in the standard
C = quantity of standard injected (ng or pg)
V (inj) = volume of sample injected (µl)
R = Recovery of the sample

7. COMPUTERIZED GAS CHROMATOGRAPHY/MASS SPECTROMETRY (GC/MS)

7.1. Operating conditions

The chemical ionisation source of a mass spectrometer can be used to produce negative ions by electron capture reactions (CI-NI-MS) using a non-reactive enhancement gas such as methane or argon. CI-NI has the advantage of being highly selective, permitting the detection of specific compounds in complex matrices. Under CI-NI conditions, methane (99.99 %) is used as the reagent gas. Samples are introduced through a SE-54, 30 m x 0.25 mm i.d., fused silica column. The film thickness used is 0.17 µm in order to minimise the bleeding of the phase into the system. Helium is used as carrier gas with an inlet pressure of 13 psi, which gives a carrier flow of 1.5 ml/min. or a gas velocity of 44 cm/sec.

The temperature of the injection port is held at 250°C.

The temperature of the source is set at 240°C, the quadrupole at 100°C and the interface at 285°C.

Injections of 1-3 µl are made in the splitless mode.

The temperature programme of the oven starts at 70°C, for 2 minutes, then it is increased at 3°C/min. to 260°C and kept under isothermal conditions for 40 minutes.

8. NOTES ON WATER ANALYSIS

The levels of lipophilic compounds in tissues of aquatic organisms and organic fractions of sediments are determined to a large extent by the levels of these compounds in the surrounding water (marine mammals are an obvious exception). Data for CBs and hydrocarbons in sea water is therefore extremely useful for an understanding of the levels in organisms. However, the levels in sea water are extremely low and consequently, their determination needs considerable experience. Large volumes of water are required and extreme care has to be taken in order to avoid contamination during sampling, extraction and clean-up of the samples. Details are described in Manual and guide No 27 of IOC, 1993 and Villeneuve J.P. (1986).

9. ALTERNATIVE PROCEDURES

9.1. Combining sample preparation and extraction for chlorinated and petroleum hydrocarbons in sediment samples.

In the event that analyses for petroleum hydrocarbons and chlorinated compounds (and/or sterols) are of interest, the following extraction procedure can be used. To the freeze-dried sample introduce internal standards for each compound class. The following are suggested: 1) aliphatic hydrocarbons: - n-C_{14} d_{30}, n-C_{19} d_{40}, n-C_{32} d_{66}, 2) polycyclic aromatic hydrocarbons: Naphthalene d_8,

Hexamethylbenzene, Cadalene (deuterated PAHs are also useful), 3) organochlorine compounds: PCB congeners 29, 30, 121 or 198, ε HCH and Endosulfan Id_4, 4) sterols: 5 α (H)-androstan-3β-ol. These standards are used for quantifying the recovery of the total procedure. Samples are Soxhlet extracted for 8 hours with 250 ml of a mixture hexane / dichloromethane (50:50), cycling the solvent through at a rate of 4 to 5 cycles per hour. The solvent extract is concentrated by rotary evaporation down to 15 ml and transferred to a Kuderna-Danish tube. It is then further concentrated down to 5-6 ml under nitrogen gas. Following removal of sulphur and water, the extract is separated into aliquots: 1/3 for petroleum hydrocarbons and sterols and 2/3 for chlorinated hydrocarbons.

Note: Mercury method should be used only if chlorinated pesticides and PCBs are analysed. If the combined method is used for petroleum and chlorinated hydrocarbons, then the copper method should be used instead of mercury that will destroy some of the PAHs.

9.2. Supercritical fluid extraction (SFE) of marine samples

Sample preparation is probably the most time-consuming and labor-intensive analytical task performed in a laboratory. Studies shows that 60 % of the overall sample analysis time is spent in sample preparation which is the main source of error and of contamination. In addition, the amount of hazardous chemicals used for sample preparation is a continuous source of concern. Due to safe handling and disposal requirements, the reduction of their use is a priority for laboratories worldwide.

Supercritical fluids are gases (i.e. N_2O and CO_2) at room temperature and pressures above the critical point. The SFE technique allows an efficient extraction of a variety of contaminants with considerable reduction in the analysis cost, sample amount and allows the extraction of the thermal sensitive substances, reducing the amount of environmentally hazardous solvents.

A small change in the pressure of a supercritical fluid results in a big change in its density and the solvent strength of the fluid changes with changing density. As a result, one supercritical fluid easily performs the work of many solvents. If this is not enough, it is possible to add a modifier, such as methanol (a few per cent) to increase the solvating range of the fluid. Therefore, SFE should speed up the sample preparation process, minimising the wastes associated with the analysis.

Until now, the main fields of analytical applications of SFE are related to environmental studies and to the food-processing industry (Hawthorne, 1990, Bayona, 1993). A method using carbon dioxide (80°C-340 atm) for the extraction of total petroleum hydrocarbons has been approved as an EPA standard method. The extraction efficiency of modified CO_2 for the recovery of 41 organochlorine and 47 organophosphorus pesticides spiked on sand at different pressures and temperatures were higher than 80%. Furthermore, by increasing the extraction temperature up to 200°C, PCBs and PAHs can be extracted from naturally occurring samples with neat CO_2. Nam *et al.* (1991), have developed a method for rapid determination of polychlorinated organics in complex matrices. The method is based on direct coupling of supercritical fluid extraction with tandem supercritical fluid chromatography and gas chromatography. The on-line system permits simultaneous extraction and analysis with high reproducibility and accuracy.

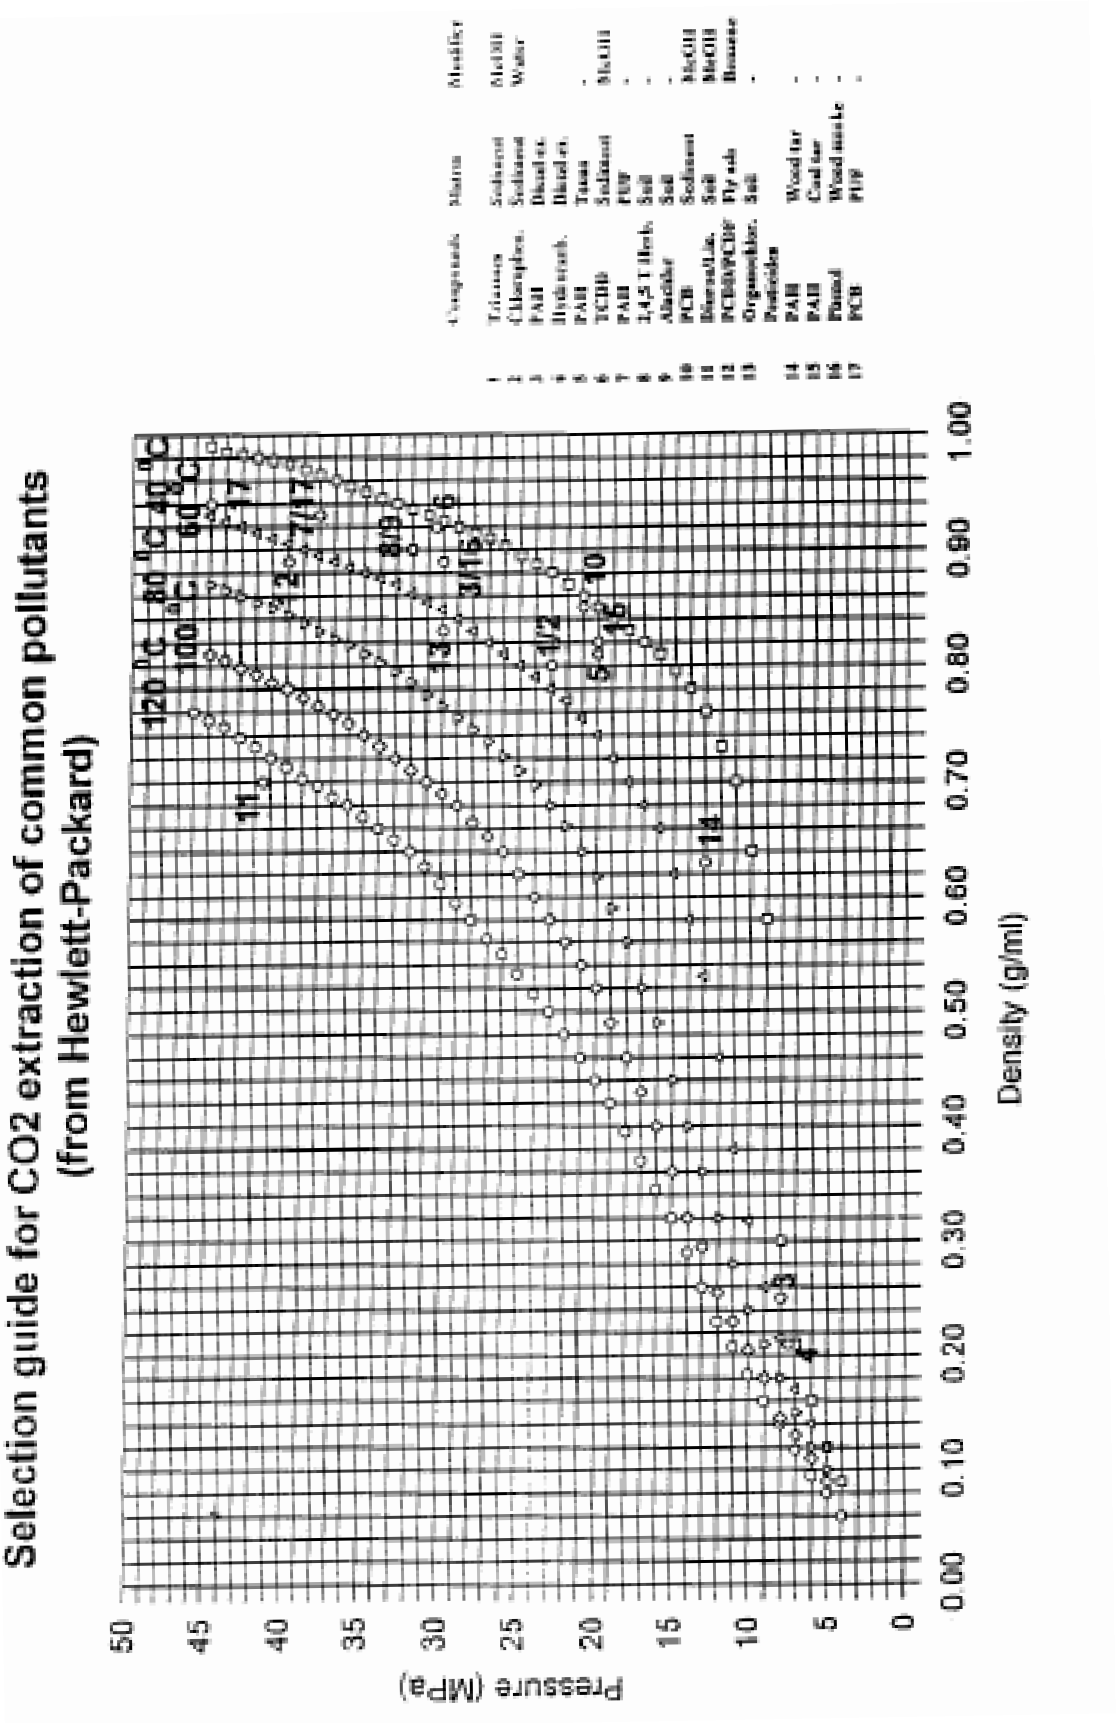

Figure 8: Guide for CO_2 extractions

9.3. Microwave assisted extraction for marine samples

9.3.1 Sediment

Another alternative method for the extraction of chlorinated hydrocarbons in sediment samples (or combined extraction for chlorinated hydrocarbons and petroleum hydrocarbons) is the use of the Microwave oven instead of the Soxhlet extractor. The main advantage of the microwave oven is the fact that, for one sample, only 40 ml of solvent mixture are used instead of 250 ml for clean-up of extraction thimbles and 250 ml for the extraction itself.

10 to 15 grams of freeze-dried sediment sample, ground and sieved at 250 µm, are put in the glass tube of the reactor. Appropriate internal standards (for OCs and/or PHs, see10.1.) are added to the sample for recovery and samples are extracted with 40 ml of a mixture of hexane / dichloromethane (50:50).

Extraction is realised within the following cycle:

- Power of the microwaves: 1200 watts
- Temperature increase to 115 °C in 10 minutes.
- Extraction maintained at 115 °C for 30 minutes
- Cooling to ambient temperature within one hour.

The carrousel containing 14 reactors, 12 samples could be extracted together with one blank and one Reference Material within 1 and half hour and with 10 times less solvent mixture than the standard Soxhlet extraction.

After cooling down to room temperature the solvent mixture is recovered in a 100 ml glass flask. The sediment is poured in a glass funnel containing a plug made of glass wool. The extracted sediment is washed with 10 - 20 ml of hexane. The extract follows then the procedure of clean-up and fractionation.

9.3.2 Biota

3 to 8 grams of freeze-dried biota sample is accurately weighted, the weight to be extracted is noted, and it is placed into the pre-cleaned glass tube of the reactor. A known amount of internal standard is added to the sub-sample in the tube before extraction. Candidate internal standards are the same than for sediment samples refers to section (5.3.1.)

Extraction is realized with 30 ml of a mixture hexane / acetone (90:10) within the following cycle:

- Power of the microwaves: 1200 watts
- Temperature increase to 115 °C in 10 minutes.
- Extraction maintained at 115 °C for 20 minutes
- Cooling to ambient temperature within one hour.

The carrousel containing 14 reactors, 12 samples could be extracted with one blank and one Reference Material within 1 and half hour and with 10 times less solvent mixture than the standard Soxhlet extraction.

After cooling down to room temperature the solvent mixture is recovered in a 100 ml glass flask. The powder of biota is poured in a glass funnel containing a plug made of glass wool. The extracted biota is washed with 10 - 20 ml of hexane. The extract is then concentrated with rotary evaporator and ready for E.O.M, clean-up and fractionation procedure.

10. DATA INTERPRETATION

10.1. DDT

The residence time of total DDT in the environment is relatively short (t1/2 = 3-5 years), so, at least 75-80 % of the current total DDT should be in the form of DDE or DDD if it was introduced into the environment before the 1975 ban. Values of Henry's law constant indicate that these compounds can reach the troposphere as vapour. These vapours are little adsorbed by airborne particulate matter and represent the major component in atmospheric chlorinated hydrocarbon levels. Vapour movements of these pollutants suggest that restrictions and regulations operating in the more technically advanced countries could only be partially effective on a worldwide basis.

The presence of the op DDT together with anomalous pp' DDT values in environmental samples indicates a recent treatment with this insecticide.

10.2. PCBs congeners

Among the 209 possible PCB congeners, seven of them: 28, 52, 101, 118, 138, 153 and 180, were selected as the most relevant because of their distribution in the chromatogram and in the chlorination range.

Recently, attention has been paid to congeners having 2 para-chlorines and at least 1 meta-chlorine. These congeners are called "coplanar" PCBs. Among the 209 congeners, 20 members attain coplanarity due to non-ortho chlorine substitution in the biphenyl ring. Three of these show the same range of toxicity as the 2,3,7,8 tetrachlorodibenzo-p-dioxin and the 2,3,7,8 tetrachlorodibenzofuran, these are the IUPAC Nº: 77, 126 and 169. These compounds should be identified and quantified in the environmental samples with high priority. They can be separated using fractionation with carbon chromatography (Tanabe *et al*., 1986).

10.3. Typical profiles of commercial mixtures

Formulations available in different countries are slightly different in their composition (Aroclor in USA, Kanechlor in Japan, Clophen in Germany, Phenoclor in France, Fenclor in Italy or Sovol in Russia). For the same global composition, such as Aroclor 1254, KC-500 or Phenoclor DP-5, the composition of individual congeners differs by 5-10 %. If a sample is collected on the French coast (therefore, contaminated with DP-5), and is quantified with DP-5 and Aroclor 1254, the difference observed in concentration could be in the order of 5-10 %. This shows the importance of choosing one common standard for the quantification of global industrial formulations or the importance of quantifying with individual congeners.

Percent contribution of individual chlorobiphenyls to Clophen A 50 and Aroclor 1254.

11. QUALITY ASSURANCE / QUALITY CONTROL

Guidelines on the QA/QC requirements for analysis of sediments and marine organisms are detailed in Reference Method No 57, "Contaminant monitoring programs using marine organisms: Quality assurance and good laboratory practice". Brief descriptions of issues that must be addressed in the course of understanding the procedures described here are given below.

11.1. Precision

The precision of the method should be established by replicate analysis of samples of the appropriate matrix. Estimate the precision of the entire analytical procedure by extracting five sub-samples from the same sample after homogenisation. Alternatively, perform replicate analysis of an appropriate certified reference material (RM; see below) containing the analytes of interest. The principal advantage of using a RM is that the material permits the simultaneous evaluation of accuracy while offering a well homogenised sample. Precision should be evaluated as a matter of course during the initial implementation procedure just before initiation of sample analysis.

11.2. Accuracy

The accuracy of the methods described here must be confirmed by analysis of a suitable RM (i.e. appropriate matrix, analytes) prior to initiation of sample analysis. Agreement between measured and certified concentrations for any individual analyte should be within 35 % and on average within 25%. It is advisable to introduce RMs on a regular basis (e.g. every 10-20 samples) as a method of checking the procedure. Further description of the preparation of control charts and criteria for data acceptance are discussed in Reference Method Nº 57.

11.3. Blanks

Blanks represent an opportunity to evaluate and monitor the potential introduction of contaminants into samples during processing. Contributions to the analyte signal can arise from contaminants in the reagents, those arising from passive contact between the sample and the environment (e.g. the atmosphere) and those introduced during sample handling by hands, implements or glassware. It is essential to establish a consistently low (i.e. with respect to analytes) blank prior to initiating analysis or even the determination of the method detection limit. In addition, it is necessary to perform blank determinations on a regular basis (e.g. every batch of samples).

11.4. Recovery

Recovery reflects the ability of the analyst to fully recover surrogate compounds introduced to the sample matrix or blank at the beginning of the procedure. The primary criteria for selection of compounds to be used for testing recovery are that they: 1) have physical (i.e. chromatographic/partitioning) properties similar to and if necessary spanning those of the analytes of interest, 2) do not suffer from interferences during gas chromatographic analysis, 3) are baseline resolved from the analytes of interest.

Recovery should be tested on all samples and blanks as a routine matter of course. Recoveries below 70% are to be considered unacceptable. Recoveries in excess of 100 % may indicate the presence of interference.

11.5. Archiving and reporting of results

Every sample should have an associated worksheet which follows the samples and the extracts through the various stages of the procedure and upon which the analyst notes all relevant details. An example of such a worksheet is given below. Each laboratory should construct and complete such a worksheet. Relevant chromatograms should be attached to the worksheet. Analyses should be grouped

and composite or summary analysis sheets archived with each group. Final disposal of the data will depend on the reasons for which it was collected but should follow the overall plan model.

All processed samples should be archived at all steps of the procedure:

- deep frozen (in the deep-freezer as it was received).
- freeze-dried (in sealed glass container kept in a dark place).
- extracted (after injection on the GC, sample extracts should be concentrated down to 1 ml and transferred into sealed glass vials, a Pasteur pipette sealed with a butane burner is adequate and cheap).

Sample: IAEA-357 : Marine Sediment

wet wt.
-------- = ..., % water in freeze dried sample determined by drying at 105°C : .....
dry wt.

.....g freeze-dried wt. extracted with hexane in Soxhlet extractor for 8 hours.

.....pg PCB Nº29, ...pg PCB Nº198, ...pg ε HCH and ….. pg Endosulfan Id_4 were added as internal standard.

The .....ml extract was reduced by rotary evaporator to approximately .....ml.

This was treated with sodium sulfate to dry the extract. Then treated with mercury to remove sulphur. This was further reduced to .....ml for lipid determinations. Corrected dry wt. : .....g.

Lipid determinations:

.....ml total extract;

10 µl aliquots weighed on micro-balance: .....mg; .....mg; .....mg.

HEOM = ...mg/g dry weight.

.....mg lipid subjected to column chromatography fractionation on Florisil.

F1: .....ml hexane

F2: .....ml hexane/dichloromethane (70:30)

F3: .....ml dichloromethane

GC determinations:

PCB Nº29 : .....ng recovered in F1 : .....% Recovery.

PCB Nº198 : .....ng recovered in F1 : .....% Recovery.

ε HCH : .....ng recovered in F2 : .....% Recovery.

Endosulfan Id_4: .....ng recovered in F3 : .....% Recovery.

Attach tabulation of individual compounds quantified in sample.

ANNEX

PREPARATION OF THE SOLUTION OF INTERNAL STANDARDS: PCB No 29, PCB No 198, ε HCH and Endosulfan I d4

Stock Solution of PCB No 29:

1 ml from the original vial (250ng/µl) should be transferred into a 100 ml volumetric flask, and then the volume is adjusted to 100 ml with hexane. This stock solution contains:

2.5 ng/µl of PCB No 29

Stock Solution of Endosulfan I d4:

1 ml from the original vial (250ng/µl) should be transferred into a 100 ml volumetric flask, and then the volume is adjusted to 100 ml with hexane. This stock solution contains:

2.5 ng/µl of Endosulfan I d_4

Working solution of internal standards:

0.5 ml from the stock solution of PCB No 29 (2.5 ng/µl) should be transferred into a 50 ml volumetric flask, then, 0.5 ml from the stock solution of Endosulfan I d4 (2.5 ng/µl) should be transferred into the volumetric flask, then 1 ml from the original vial (1ng/µl) of ε HCH should be transferred into that volumetric flask, then 0.5 ml from the concentrated solution (2ng/µl) of PCB No 198, and the volume adjusted to 50 ml with hexane. This working solution contains:

25 pg/µl of PCB No 29
20 pg/µl of PCB No 198
20 pg/µl of ε HCH
25 pg/µl of Endosulfan I d4

CAUTION: VIALS SHOULD BE COOLED AT 20°C PRIOR TO OPENING

Preparation of the Aroclor 1254 solution

Preparation of the stock solution:

1 ml from the original vial should be transferred into a 100 ml volumetric flask, then, the volume is adjusted to 100 ml with hexane. This stock solution contains:

6.5 ng/µl of Aroclor 1254

Preparation of the working solution:

1 ml from this stock solution should be transferred into a 50 ml volumetric flask and the volume adjusted to 50 ml with hexane. This working solution contains :

0.13 ng/µl of Aroclor 1254

CAUTION : VIAL SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of the Aroclor 1260 solution

Preparation of the stock solution:

1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5.44 ng/µl of Aroclor 1260

Preparation of the working solution:

1 ml from the stock solution should be transferred into a 50 ml volumetric flask, then the volume is adjusted to 50 ml with hexane. This working solution contains

0.1088 ng/µl of Aroclor 1260

CAUTION: VIAL SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of the pp' DDE, pp' DDD and pp' DDT solution

pp' DDE:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This stock solution contains:

5 ng/µl of pp' DDE

pp' DDD:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of pp' DDD

pp' DDT:

Stock solution: 1 ml of the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This stock solution contains:

5 ng/µl of pp' DDT

Working solution: pp' DDE, pp' DDD and pp' DDT together.

1 ml from the stock solution of pp' DDE, 2 ml of the stock solution of pp' DDD and 3 ml of the stock solution of pp' DDT should be transferred into a 100 ml volumetric flask and the volume adjusted to 100 ml with hexane. This solution contains

- pp' DDE : 50 pg/µl
- pp' DDD : 100 pg/µl
- pp' DDT : 150 pg/µl

NOTE: Further dilution may be necessary depending on the sensitivity of the EC Detector.

CAUTION: VIAL SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of Aldrin, Diedrin and Endrin standard solutions:

Aldrin:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of Aldrin

Dieldrin:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of Dieldrin

Endrin:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of Endrin

Working solution: Aldrin, Dieldrin and Endrin together.

1 ml from the stock solution of Aldrin, 1 ml from the stock solution of Dieldrin and 1 ml from the stock solution of Endrin are transferred into a 100 ml volumetric flask and the volume is adjusted to 100 ml with hexane. This working solution contains:

Aldrin	:	50 pg/µl
Dieldrin	:	50 pg/µl
Endrin	:	50 pg/µl

NOTE: Further dilution may be necessary depending on the sensitivity of the detector.

CAUTION: VIALS SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of the HCB and Lindane standard solutions:

HCB:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of HCB

Lindane:

Stock solution: 1 ml from the original vial should be transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

5 ng/µl of lindane

Working solution:

1 ml from the stock solution of HCB and 1 ml from the stock solution of Lindane are transferred into a 100 ml volumetric flask, then the volume is adjusted to 100 ml with hexane. This solution contains:

HCB	:	50 pg/µl
Lindane	:	50 pg/µl

NOTE: further dilution may be necessary depending on the sensitivity of the EC Detector.

CAUTION: VIALS SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Preparation of the PCB congeners solution

In a 100 ml volumetric flask, transfer 1 ml from the original vial. Adjust to 100 ml with hexane in order to obtain the working solution with the following concentrations:

CB Nº:	Compounds:	Concentrations (pg/µl)
8	2,4’	17.50
18	2,2’,5	12
31	2,4’,5	10.6
28	2,4,4’	4.6
52	2,2’,5,5’	8.6
49	2,2’,4,5’	12.1
44	2,2’,3,5’	10.7
66	2,3’,4,4’	5.5
95	2,2’,3,5’,6	5.7
101	2,2’,4,5,5’	9.3
110	2,3,3’,4’,6	11.1
149	2,2’,3,4’,5’,6	12.1
118	2,3’,4,4’,5	8.5
153	2,2’,4,4’,5,5’	8.4
138	2,2’,3,4,4’,5’	13.8
183	2,2’,3,4,4’,5’,6	10.3
174	2,2’,3,3’,4’,5,6’	9.4
177	2,2’,3,3’,4’,5,6	9.5
180	2,2’,3,4,4’,5,5’	16.3
170	2,2’,3,3’,4,4’,5	13.4
199	2,2’,3,3’,4,5,5’,6’	9.3
194	2,2’,3,3’,4,4’,5,5’	12.6

Separate into 10 volumetric flasks of 10 ml, seal with Teflon tape and keep in refrigerated place in order not to evaporate them.

CAUTION: VIAL SHOULD BE COOLED TO 20 °C PRIOR TO OPENING

Manual for marine monitoring in the COMBINE programme
ANNEX B-12, APPENDIX 3. TECHNICAL NOTE ON THE DETERMINATION OF CHLORINATED BIPHENYLS AND ORGANOCHLORINE PESTICIDES IN BIOTA

HELCOM Manual for marine monitoring in the COMBINE programme

ANNEX B-12, APPENDIX 3. TECHNICAL NOTE ON THE DETERMINATION OF CHLORINATED BIPHENYLS AND ORGANOCHLORINE PESTICIDES IN BIOTA

1. INTRODUCTION

The analysis of chlorinated biphenyls (CBs) and organochlorine pesticides (OCPs) in fish samples generally involves extraction from the respective matrix with organic solvents, followed by clean-up and gas chromatographic separation with electron capture (GC-ECD) or mass spectrometric (GC-MS) detection.

The analytical procedure is liable to systematic errors due to insufficiently optimized gas chromatographic conditions, determinant losses (evaporation, unsatisfactory extraction yield), and/or contamination from laboratory ware, reagents and the laboratory environment. It is therefore essential that the sources of systematic errors are identified and eliminated as far as possible.

In the following paragraphs, the guidelines drafted by the OSPAR Ad Hoc Working Group on Monitoring (OSPAR, 1996) have been taken into consideration.

2. PRE-TREATMENT OF LABORATORY WARE AND REAGENTS; CONTAMINATION CONTROL

Glassware, reagents, solvents, column adsorption materials and other laboratory equipment that come into contact with the sample material to be analysed should be free of impurities that interfere with the quantitative determination of CBs and OCPs.

For cleaning purposes, the following procedures should be followed:

1. Glassware should be thoroughly washed with detergents, dried with acetone and rinsed with a non-polar solvent such as *n*-pentane, and heated to > 100 ^{o}C prior to use.

2. Glass fibre Soxhlet thimbles should be pre-extracted with an organic solvent. The use of paper Soxhlet thimbles should be avoided. Alternatively, glass fibre thimbles or full glass Soxhlet thimbles, with a G1 glass filter at the bottom, are recommended.

3. Solvents should be checked for impurities using GC after concentrating the volume normally used in the procedure to 10 % of the final volume. If necessary, solvents can be purified by controlled re-distillation and rectification over KOH in an all-glass distillation column.

4. Reagents and column adsorption materials should be checked for contamination before use by extraction with an organic solvent (e.g., *n*-pentane) and analysis by GC, using the detector which will also be used for the final determination (ECD or MS).

5. Laboratory air can also be contaminated with CBs, OCPs or compounds interfering with the CB/OCP analysis. A good estimation of the contamination of the air can be found by placing a petri dish with 2 grams of C18-bonded silica for two weeks in the laboratory. After this period, the material is transferred to a glass column and eluted with 10 ml of 10% diethylether in hexane. After concentrating the eluate, the CB concentrations can be measured. Absolute amounts of <1 ng show that the contamination of the air is at an acceptably low level in that laboratory (Smedes and de Boer, 1994).

3. SAMPLE PRETREATMENT

To ensure complete extraction of the lipophilic CBs and OCPs from biological sample matrices, it is essential to dry the material and disrupt the cell walls of the biological matrix to be analysed. This can be achieved by Ultra Turrax mixing or grinding of the sample with a dehydrating reagent, such as Na_2SO_4, followed by multiple solid/liquid extraction with a mixture of polar and non-polar solvents (e.g., acetone/hexane or methanol/dichloromethane). It is essential to allow complete binding of the water present in the sample with the dehydrating reagent (this requires at least several hours) prior to starting the extraction step. The extraction efficiency must be checked for different types and amounts of biological matrices to be investigated (see 'recovery section').

4. CLEAN-UP

The crude extract obtained from sample pretreatment requires a clean-up in order to remove co-extracted lipophilic compounds that interfere with the gas chromatographic determination of CBs and OCPs. Normal-phase solid/liquid chromatography, using deactivated Al2O3 or deactivated silica as adsorbents and hexane or iso-octane as solvents, is an appropriate technique for the separation of the determinands from lipids or other interfering compounds. Effective removal of high molecular weight compounds can be achieved by gel permeation chromatography (GPC). However, GPC does not separate CBs from other compounds in the same molecular range, such as organochlorine pesticides (OCPs). Therefore, additional clean-up may be required. Treatment of the OCP fraction with concentrated H_2SO_4 can improve the quality of the subsequent gas chromatogram. However, this treatment is not recommended if determinands of the dieldrin type or heptachloroepoxides, which are easily broken down by H2SO4, are to be determined.

5. DETERMINATION BY GAS CHROMATOGRAPHY

Because of the large number of organochlorine compounds to be determined, high resolution gas chromatography (GC) using, preferably narrow bore, fused silica wall-coated open-tubular (capillary) columns is necessary.

Carrier gas
Hydrogen is the preferred carrier gas and is indispensable for columns with very small inner diameters. For safety reasons, hydrogen should not be used without a safety module which is able to check for small hydrogen concentrations inside the GC oven coming from possible leakages. As a compromise to safety aspects, helium is also acceptable.

Columns
In order to achieve sufficient separation, capillary columns should have a length of >60 m, an internal diameter of < 0.25 mm (for diameters below 0.18 mm the elevated pressure of the carrier gas needs special instrumentation) and a film thickness of the stationary phase of < 0.25 µm. For routine work, the SE 54 (Ultra 2, DB 5, RTx 5, CP-Sil 8) phase (94 % dimethyl-, 5 % phenyl-, 1 % vinyl-polysiloxane) or medium polar columns (CP-Sil 19, OV-17, OV 1701, DB 17) have been shown to give satisfactory chromatograms. A second column with a stationary phase different, from that used in the first column, may be used for confirmation of the peak identification.

Injection
Splitless and on-column injection techniques may both be used. Split injection is not recommended because strong discrimination effects may occur. Other techniques such as temperature-programmed or pressure-programmed injection may have additional advantages, but should be thoroughly optimized before use.

In splitless injection, the volume of the liner should be large enough to contain the gas volume of the evaporated injected solvent. If the liner is too small, memory effects can occur due to contamination of the gas tubing attached to the injector. Very large liner volumes, in contrast, can cause a poor transfer of early eluting components.

A 1 µl injection normally requires a ca. 1 ml liner. The occurrence of memory effects should be tested by injection of iso-octane after analysis of a CB or OCP standard. The use of a light packing of silylated glass wool in the liner improves the response and reproducibility of the injection. However, some organochlorine pesticides such as DDT may disintegrate when this technique is used. In splitless injection, discrimination effects can occur.

The splitless injection time should therefore be optimized to avoid discrimination. This can be done by injecting a solution containing an early-eluting and a late-eluting CB, e.g., CB28 and CB180. Starting with a splitless injection time of 0.5 minutes, the peak height of the late-eluting compound will presumably increase relative to that of the first compound. The optimum is found at the time when the increase does not continue any further. The split ratio is normally set at 1:25 and is not really critical. The septum purge, normally approximately 2 ml min-1, should be stopped during injection. This option is not standard in all GCs.

Due to the variety of on-column injectors, a detailed optimization procedure cannot be given. More information on the optimization of on-column parameters may be obtained from Snell *et al*. (1987).

The reproducibility of injection is controlled by the use of an internal standard not present in the sample.

Detector

Quantitative analysis is performed by comparing the detector signal produced by the sample with that of defined standards. The use of an electron capture detector (ECD) sensitive to chlorinated compounds or - more generally applicable - a mass selective detector (MSD) or (even) a mass spectrometer (MS) is essential.

Due to incomplete separation, several co-eluting compounds can be present under a single detector signal. Therefore, the shape and size of the signal have to be critically examined. With a MSD or MS used as detector, either the molecular mass or characteristic mass fragments should be recorded for that purpose. If only an ECD is available, the relative retention time and the signal size should be confirmed on columns with different polarity of their stationary phases, or by the use of multi-dimensional GC techniques (de Boer *et al*., 1995; de Geus *et al*., 1996).

Calibration

Stock solutions of individual organohalogen compounds should be prepared using iso-octane as the solvent and weighed solid individual standard compounds of high purity (> 99 %). Stock solutions can be stored in measuring flasks in a refrigerator or in a dessicator with a saturated atmosphere of iso-octane, but losses can easily occur, particularly when storing in refrigerators (Law and de Boer, 1995). Loss of solvents in stock solutions can be controlled by recording the weight and filling up the missing amount before a new aliquot is taken. However, aliquots stored in sealed glass ampoules are much more appropriate and can normally be stored for several years. Fresh stock standard solutions should be prepared in duplicate and compared with the old standard solutions. Working standards should be prepared gravimetrically from stock solutions for each sample series. All manipulations with solvents, including pipetting, diluting and concentrating, should preferably be checked by weighing. Due to day-to-day and season-to-season temperature differences in laboratories and due to the heating of glassware after cleaning, considerable errors can be made when using volumetric glassware as a basis for all calculations.

The GC should be calibrated before each batch of measurements. Since the ECD has a non-linear response curve, a multilevel calibration is strongly advised. Megginson *et al*. (1994) recommend a set of six standard solutions for CB determination or five standard solutions for OCP determination. Standards used for multilevel calibration should be regularly distributed over the sample series, so that matrix and non-matrix containing injections alternate.
When concentrations of compounds in the sample fall outside either side of the calibration curve, a new dilution or concentrate should be made and the measurement repeated. Considerable errors can be made when measuring concentrations which fall outside the calibration curve.

For MS detection, a multi-level calibration is also recommended.

Recovery
For the purpose of determining recovery rates, an appropriate internal standard should be added to each sample at the beginning of the analytical procedure. The ideal internal standard is a CB which is not present in the sample and which does not interfere with other CBs. All 2,4,6-substituted CB congeners are, in principle, suitable. Alternatively, 1,2,3,4-tetrachloronaphthalene or the homologues of dichloroalkylbenzylether can be used. For GC with mass selective detection (GC-MSD), 13C-labelled CBs must be used as internal standards. With GC/MS, 13C-labelled CBs should preferably be used as internal standards.

CEMP Guidelines for Monitoring Contaminants in Sediments

(OSPAR Agreement 1999-02)

Technical Annex 8: Determination of chlorobiphenyls in biota

1. Introduction

This technical annex provides advice on chlorobiphenyl (CB) analysis for all biota samples. The guideline is an update of an earlier version (OSPAR, 1999) taking into account evolutions in the field of analytical chemistry and also covering the determination of the planar CBs, i.e. the mono-*ortho* (CB105, CB114, CB118, CB123, CB156, CB157, CB167 and CB189) and non-*ortho* substituted CBs (CB81, CB77, CB126 and CB169). When reviewing the literature, it should be noted that planar, coplanar and dioxin-like CBs / PCBs are all equivalent terms.

The analysis of CBs in biota generally involves extraction with organic solvents, clean-up (removal of lipids and fractionation), and gas chromatographic separation with electron capture or mass-spectrometric detection. All stages of the procedure are susceptible to insufficient recovery and/or contamination. Where possible, quality control procedures are required in order to check the method's performance. These guidelines are intended to encourage and assist analytical chemists to reconsider their methods and to improve their procedures and/or the associated quality control measures where necessary. Due to the low concentrations of, particularly, non-*ortho* substituted CBs in biota compared to those of other CBs, their determination requires an additional separation and concentration step. Therefore, in the relevant sections a distinction will be made between the non-*ortho* CBs and the others.

These guidelines can also be used for several other groups of organochlorine compounds, e.g. DDTs and their metabolites, chlorobenzenes and hexachlorocyclohexanes. Recoveries in the clean-up procedures must be checked carefully. In particular, treatment with H_2SO_4 results in a loss of some compounds (e.g. dieldrin and endosulfan (de Boer and Wells, 1996)).

These guidelines are not intended as a complete laboratory manual. If necessary, further guidance should be sought from specialised laboratories. Whichever analytical procedure is adopted, the laboratory must demonstrate the validity of the procedure. Analyses must be carried out by trained staff.

2. Analysis

2.1. Precautionary measures

Solvents, chemicals and adsorption materials must be free of CBs or other interfering compounds. If not they should be purified using appropriate methods. Solvents should be checked by concentrating the volume normally used in the procedure to 10% of the final volume if practical and then analysing for the presence of CBs and other interfering compounds. If necessary, the solvents can be purified by

redistillation but this practice is not favoured by most analytical laboratories as they generally opt to purchase high quality solvents directly. Chemicals and adsorption materials should be purified by extraction and/or heating. Glass fibre materials (*e.g.* thimbles for Soxhlet extraction) should be pre-extracted. Alternatively, glass thimbles with a G1 glass filter at the bottom can be used. Generally, paper filters should be avoided in filtration and substituted for by appropriate glass filters. As all pre-cleaned materials are prone to contamination (*e.g.* by the adsorption of CBs and other compounds from laboratory air), materials ready for use should not be stored for long periods. All containers, tools, glassware *etc.* which come into contact with the sample must be made of appropriate material and must have been thoroughly pre-cleaned. Glassware should be extensively washed with detergents, heated at >250°C and rinsed immediately before use with organic solvents or mixtures such as hexane/acetone. In addition all glassware should preferably be covered with aluminium foil and stored in cupboards to keep out any dust. Old and scratched glassware is more likely to cause blank problems because of the larger surface and therefore greater chance of adsorption. Furthermore, scratched glassware can be more difficult to clean effectively, as shown during analysis of brominated flame retardants (QUASIMEME, 2007).

2.2 Lipid determination

The determination of the lipid content of tissues can be of use in characterising the samples and reporting concentrations in biota on a wet weight or lipid weight basis. The total lipid content of fish or shellfish should be determined using the method of Bligh and Dyer (1959) as modified by Hanson and Olley (1963) or an equivalent method such as Smedes (1999). Extractable lipid methods may be used, particularly if the sample size is small and lipid content is high. It has been shown that if the lipid content is high (> 5%) then the extractable lipid content will be comparable to that of the total lipid. If extraction techniques are applied which destroy or remove lipid materials (e.g., PLE with fat retainers), the lipid content should be determined on a separate subsample of the tissue homogenate. Other relevant information concerning lipid determination are provided by QUASIMEME, 1994 and Roose *et al*., 1996.

2.3. Dry weight determination

Dry weight determinations should be carried out by drying homogenised sub-samples of the material to be analysed to constant weight at 105°C.

2.4. Homogenisation and drying

Prior to analysis, the samples should be sufficiently homogenised. Homogenisation is generally carried out on fresh tissue. Care should be taken that the sample integrity is maintained during the actual homogenisation. When the analysis is undertaken, all fluids that may initially separate on thawing should be included with the materials homogenised. Homogenisation should be performed prior to extraction and clean-up procedures. When homogenising samples after drying, classical techniques using a ball mill can be used. Cryogenic homogenisation of dried or fresh materials at liquid nitrogen temperatures using a PTFE device (*cf.* Iyengar and Kasperek, 1977) or a similar technique is also possible (*cf.* Iyengar, 1976; Klussmann *et al*., 1985).

CBs can be extracted from either wet or dried samples, although storage, homogenisation and extraction are easier when the samples are dry. Drying the samples may, however, alter the CB concentrations e.g. by the loss of compounds through evaporation or by contamination. Potential losses and contamination should be checked as part of the method validation.

Chemical drying can be performed by grinding with e.g. Na_2SO_4 or $MgSO_4$ until the sample reaches a free-flowing consistency. It is essential that at least several hours elapse between grinding and extraction to allow for complete dehydration of the sample, as the presence of residual water will decrease the extraction efficiency.

Freeze-drying is also a popular technique, although its application should be carefully considered. Possible losses or contamination must be checked. Losses through evaporation are diminished by keeping the temperature in the evaporation chamber below 0°C. Contamination during freeze-drying can be reduced by putting a lid, with a hole of about 3 mm in diameter, on the sample container.

2.5. Extraction

Recovery standards should be added prior to extraction. When using Soxhlet extraction, a combination of polar and apolar solvents is recommended. Alternatively, saponification may be used. This technique is highly effective, but conditions should be controlled as saponification could result in the decomposition of some pesticides and, under certain conditions, of some CB congeners.

Although the use of binary non-polar/polar solvent mixtures and Soxhlet extraction is still the benchmark for CB extraction, there have been numerous attempts to find alternative procedures, which are less time-consuming, use less solvent and/or enable miniaturisation. Amongst these novel approaches are pressurised liquid extraction (PLE) and related subcritical water extraction (SWE), microwave-assisted extraction (MAE), matrix solid-phase dispersion (MSPD), ultrasound extraction (US) and supercritical fluid extraction (SFE).

From among the techniques mentioned, PLE or Accelerated Solvent Extraction (ASE) has – so far – been most successful. Soxhlet methods are easily translated into PLE as the same solvent compositions can be used. The method further allows interesting modifications that include in-cell clean-up of samples by adding fat retainers, such as acid-impregnated silica, florisil or alumina, to the cell. New promising techniques have been described, e.g. the use of a small carbon column in the extraction cell, which selectively adsorbs dioxin-like compounds (subsequently isolated by back-flushing with toluene), but these are not established for routine analysis (Sporring *et al*., 2003). PLE and MAE have the shared advantage over SFE that they are matrix-independent, which facilitates method development and changing-over from the classical Soxhlet extraction. Recent years have also seen an increased use of ultrasound-based techniques for the isolation of analytes from solid samples. With most applications, extraction efficiency is satisfactory, and sonication time often is 30 min or less (Roose and Brinkman, 2005).

All the methods described above are in principle suitable for extracting CBs from biota. However, Soxhlet extraction is still the reference for alternative approaches.

2.6 Clean-up

The extraction procedures above will result in the co-extraction of lipids, which will need to be removed from the extract. Furthermore, tissue extracts will always contain many compounds other than CBs, and a suitable clean-up is necessary to remove those compounds which may interfere with the subsequent analysis. Different techniques may be used, either singly or in combination, and the choice will be influenced by the selectivity and sensitivity of the final measurement technique and also by the extraction method employed. Most CBs are stable under acid conditions; therefore treatment with sulphuric acid or acid impregnated silica columns may be used in the clean-up.

The most commonly used clean-up methods involve the use of alumina or silica adsorption chromatography, but gel permeation chromatography (GPC) is also employed. Any water residues in the extract should be removed prior to clean-up, e.g. by adding Na_2SO_4.

As CBs are apolar, clean-up using normal-phase chromatography is the most appropriate technique for their separation from other compounds. Using an apolar solvent (*e.g.* hexane or *iso*-octane) as an eluent, CBs normally elute very rapidly. All polar solvents used in the extraction should be removed before further clean-up. The last concentration step is usually performed by evaporation with a gentle stream of nitrogen. Evaporation to dryness should always be avoided but, for the analysis of planar CBs, very small final sample extract volumes might be necessary to achieve detectable concentrations.

Deactivated Al_2O_3 (5-10% water) is often used as a primary clean-up technique. Al_2O_3 can yield a sufficiently clean extract for a GC-ECD analysis of the sample. Al_2O_3 effectively removes lipid compounds from the extracts (although samples with a very high lipid content and low CB concentrations may require additional clean-up).

Deactivated silica (1-5% water) does not retain CBs (including non-*ortho* CBs) and only retains polycyclic aromatic hydrocarbons (PAHs) slightly when eluted with hexane or *iso*-octane. When organochlorine pesticides are also to be determined in the same extract, deactivation of the silica with a few percent of water is necessary.

For high activity silica (heated overnight at 180°C) the retention of CBs is negligible, while PAHs are more strongly retained. The CBs and a few other organochlorine compounds can be eluted with apolar solvents. More polar solvents (*e.g.* hexane/acetone) should be avoided as some interfering organochlorine pesticides would be eluted as well.

For the separation of CBs from lipids or oil components, reversed-phase HPLC can be used. In reversed-phase chromatography, CBs elute during a solvent gradient of 80 to 90% methanol together with numerous other compounds of the same polarity. Most of the above mentioned extraction methods and clean-up procedures yield an extract containing an apolar solvent. These cannot be injected directly for reversed-phase chromatography, and so compounds must be transferred between solvents several times *e.g.* before injection and after elution. When using polar solvents for extraction, reversed-phase columns could be used directly for clean-up. When eluting an acetonitrile extract from a C_{18} solid phase extraction (SPE) column with acetonitrile, high molecular hydrocarbons are strongly retained while CBs elute in the first few column volumes.

The above mentioned normal-phase chromatographic procedures on silica and Al_2O_3 can be transferred to HPLC having the advantages of higher resolution and better reproducibility.

When using GPC, the elution of CBs should be carefully checked. Two serial columns are often used for improved lipid separation. Solvent mixtures such as dichloromethane/hexane or cyclohexane/ethyl acetate can be used as eluents for GPC. However, a second clean-up step is often required to separate the CBs from other organohalogenated compounds and/or to remove residual lipids.

One advantage of using PLE extraction is that it is possible to combine the clean-up with the extraction, especially where mass spectrometry will be used as the detection method. If Soxhlet extraction is used for biota, then there is a much greater quantity of residual lipid to be removed than in the case of PLE with fat retainers. An additional clean-up stage may therefore be necessary. Methods have been developed for online clean-up and fractionation of dioxins, furans and CBs with PLE for food, feed and

environmental samples (Sporring *et al*., 2003), utilising a fat retainer for the on-line clean-up of fat. Silica impregnated with sulphuric acid, alumina and florisil have all been used as fat retainers. A non-polar extraction solvent such as hexane should be used if fat retainers are used during PLE.

Non-*ortho* CBs require a more specialised clean-up that is generally associated with the analysis of dioxins. Although initial clean-up may very well proceed along the lines described above, the larger sample intake results in the presence of even more co-extractive compounds and care has to be taken that the capacity of the adsorption columns is not exceeded and/or that lipids are adequately removed. Often, more rigorous procedures are applied to remove the excess material by e.g. shaking the sample with concentrated sulphuric acid. A more efficient alternative is to elute the sample over a silica column impregnated with sulphuric acid (40 % w/w).

Non-*ortho* CBs are nearly always separated from the other CBs using advanced separation techniques. One very efficient method is to inject the extracts (after concentrating them) into a HPLC system coupled to a PYE (2-(1-pyrenyl) ethyldimethylsilylated silica) column. Column dimensions are typically 4.6 x 150 mm, but combinations of several columns in-line are sometimes used. The use of PYE columns not only allow the separation of ortho, mono-ortho and non-ortho CBs from one another on the basis of structural polarity, but also from dibenzo-p-dioxins and dibenzofurans. The eluting solvent is an apolar solvent such as iso-hexane. Coupled to a fraction collector, the use of a HPLC system allows the automatic clean-up of a considerable number of samples at a time. Alternatively, HPLC systems equipped with porous graphitised carbon can be used. Column sizes are in the order of 50 x 4.7 mm and care has to be taken that the column is not overloaded. Similarly to PYE columns, they will separate non-*ortho* CBs from the other CBs and from dioxins. Fully automated systems, such as Powerprep™, that combine several steps are routinely used.

2.7 Pre-concentration

Evaporation of solvents using a rotary-film evaporator was, until recently, the most common method. However, evaporation of solvents using this technique should be performed at low temperature (water bath temperature of ≤ 40°C) and under controlled pressure conditions, in order to prevent losses of the more volatile CBs. To reduce the sample to the final volume, solvents can be removed by blowing-down with a gentle stream of nitrogen. Only nitrogen of a controlled high quality should be used.

Turbovap sample concentrators can also be used to reduce solvent volume. This is a rapid technique, but needs to be carefully optimised and monitored to prevent both losses (both of volatiles and solvent aerosols) and cross-contamination. The use of rotary-film evaporators is more time consuming but more controllable. Here also, evaporation to dryness should be avoided at all costs. Syncore™ parallel evaporators (Buchi, Switzerland) can be used with careful optimisation of the evaporation parameters. The Buchi Syncore™ Analyst also uses glass tubes but the system is sealed, avoiding contamination from the laboratory air during evaporation. It does not use a nitrogen stream, thus reducing the loss of volatiles and if the flushback module is fitted the sides of the tubes are rinsed automatically thus reducing the loss of the heavier components. Again water-bath temperatures should be minimised to prevent losses. When reducing the sample to the required final volume, solvents can be removed by a stream of clean nitrogen gas. Suitable solvents for injection into the gas chromatograph (GC) include hexane, heptane, toluene and *iso*-octane.

2.8 Calibration and preparation of calibrant solutions

Internal standards (recovery and quantification standards) should be added in a fixed volume or weight to all standards and samples. The ideal internal is a CB which is not found in the samples. All CBs with a 2,4,6-substitution (e.g. CB112, CB155, CB198) are, in principle, suitable for this purpose. Alternatively, 1,2,3,4-tetrachloronaphthalene or homologues of dichloroalkylbenzylether can be used. For GC analysis with mass selective detection (GC-MS), 13C labelled CBs should be used at each degree of chlorination. This is especially critical for the determination of the non-ortho CBs. If possible, the labelled calibrant solutions should correspond to the unlabelled determinants. For the non-ortho CBs, a labelled standard is available for each congener and use of all of them is recommended. When preparing a calibration solution for a new determinant for the first time, two independent stock solutions of different concentrations should always be prepared simultaneously to allow cross checking. A new calibration solution should also be cross-checked to the old standard solution. Crystalline CBs of known purity can be used for preparing calibration solutions but, for health and safety reasons, the purchase of solutions is recommended for planar CBs. In recent years, a lot of certified commercial custom made standards have become available and laboratories have been switching to these. If the quality of the standard materials is not guaranteed by the producer or supplier, it should be checked by GC preferably with mass spectrometric detection. Solid standards should be weighed to a precision of 10-5 grams. Calibration solutions should preferably be stored in ampoules in a cool and dark place. Commercially available screw-cap vials with a capillary opening (CertanTM) combine of advantages of ampoules and vials, and, have proven to be reliable. When stored in containers the weight loss during storage should be recorded.

2.9 Instrumental determination

2.9.1 Injection techniques

The two modes commonly used are splitless and on-column injection as, in split injection, strong discrimination effects may occur. The liner should possess sufficient capacity with respect to the injected volume after evaporation, but should not be oversized so as to avoid poor transfer to the column and losses by adsorption. Liners with a light packing of (silylated) glass wool may improve the performance for CBs, but may cause degradation of some organochlorine compounds like DDT, which are often included in national monitoring programmes.

Recently, other techniques such as temperature-programmed or pressure-programmed injection have become more prominent. They offer additional advantages such as an increased injection volume without the negative effects previously associated with that technique, but should be thoroughly optimised before use. Increasing the injection volume will allow either the elimination of an extra evaporation step or the lowering of the analytical detection limits, or both.

2.9.2 Carrier gas

Hydrogen is the preferred carrier gas and is indispensable for columns with very small inner diameters. Helium is also acceptable and is the standard carrier gas for use with GC-MS techniques.

2.9.3 Columns

Only capillary columns should be used. The following parameters are recommended:

Minimum Length	50 m (for microcolumns of internal diameter <0.1 mm, shorter columns can be suitable).

Maximum internal diameter	0.25 mm. Note that for diameters <0.15 mm the elevated pressure of the carrier gas needs special instrumental equipment as most of the instruments are limited to 400 kPa.
Film thickness	0.2 - 0.4 µm.

Columns which do not fulfil these requirements generally do not offer sufficient resolution to separate CB28, CB105 and CB156 from closely eluting CBs. A wide range of stationary phases can be used for CB separation. The chemical composition is different for columns from different producers and this influences the maximum temperature at which the column can be operated. Further advice may be found in the producers' catalogues, where compositions, applications and tables from which to compare products from different manufacturers are included.

In recent years, new chromatographic phases have become available that result in an improved separation of critical CB pairs. A good example is the HT-8 phase (1,7-dicarba-closo-dodecarborane phenylmethyl siloxane) (Larsen *et al*., 1995) that shows a remarkable selectivity for CBs (Table 1). This column is currently recommended for CB analysis.

2.9.4 Detection

The electron capture detector (ECD) is still frequently used for CB analysis. Injection of chlorinated solvents or oxygen-containing solvents should be avoided when ECD is used due to the generation of large interfering signals. When using mass selective detectors (MSD), the electron-capture negative-ion chemical ionisation mode (ECNICI) is extremely sensitive for pentachlorinated to decachlorinated CBs, and is approximately ten fold more sensitive than ECD. However, the sensitivity of MS systems has improved considerably, allowing analysis also to be undertaken using electron impact ionisation (EI). Previously, the use of ECNICI was often necessary in order to detect the low concentrations of, in particular, the non-*ortho* CBs. Suggested target and qualifier ions for *ortho* CBs (including mono-*ortho* CBs) are shown in Table 1 and in Table 2 for non-*ortho* CBs.

Next to conventional GC-MS, the use of ion-trap with its tandem MS^2 option – i.e., yielding improved selectivity – is receiving increased attention. The use of GC-ITMS provides a less expensive alternative to high-resolution mass spectrometry (HRMS), which is commonly used to determine PCDD/Fs and, as such, is also ideally suited for the detection of all CB groups.

Table 1: Example of retention times for selected CB congeners using a 50 m HT8 column (0.25 mm i.d. and 0.25 µm film), along with possible target and qualifier ions. Temperature programme: 80°C, hold for 1 minute, ramp 20°C/minute, to 170 °C, hold 7.5 minutes, ramp 3 °C/minute to 300 °C, hold for 10 minutes.

2.9.5 Separation, identification and quantification

When using GC-ECD and, to a certain extent, GC-MS, two columns with stationary phases of different polarity should be used, as column-specific co-elution of the target CBs with other CBs or other organochlorine compounds can occur on a single column. Using columns of differing selectivity's can resolve these co-elution problems. The temperature programme used must be optimised for each column to achieve sufficient separation of the CB congeners to be determined. An isothermal period in the programme around 200-220°C of approximately 30 minutes is recommended. Care should be taken that CBs of interest do not coelute with other CB congeners (for example CB28 and CB31). When using GC-ECD, compounds are identified by their retention time in relation to the standard solutions under the same conditions. Therefore GC conditions should be constant. Shifts in retention times should be checked for different areas of the chromatogram by identifying characteristic, unmistakable peaks (*e.g.* originating from the internal standard or higher concentrated CBs such as CB153 and CB138. Using a GC-MS system, the molecular mass or characteristic mass fragments or the ratio of two ion masses can be used to confirm the identity of resolved CBs. Since calibration curves for most CBs are usually non-linear when using GC-ECD, but should be linear when using GC-MS, a multilevel calibration of at least five concentrations is recommended. The calibration curve must be controlled and the best fit must be applied over the relevant concentration range. One should strive to work within the linear range of the detector. Analysis of the calibration solutions should be carried out in a mode encompassing the concentrations of the sample solutions (or alternatively by injecting matrix-containing sample solutions and matrix-free standard solutions distributed regularly over the series). When the chromatogram is processed with the help of automated integrators, the baseline may not always be set unambiguously and always needs to be inspected visually. When using GC-ECD, peak height is preferable to peak area for quantification purposes. From the two columns of different polarity the more reliable result (in terms of absence of co-elutions) should be reported.

Recent years have witnessed the emergence of so-called comprehensive two-dimensional gas chromatography (GC x GC) – a technique that can be used to considerably improve analyte/matrix as well as analyte/analyte separation. Briefly, a non-polar x (semi-)polar column combination is used, with a conventional 25–30 m long first-dimension, and a short, 0.5-1 m long, second-dimension column. The columns are connected via an interface called a modulator. The latter device serves to trap, and focus, each subsequent small effluent fraction from the first-dimension column and, then, to launch it into the second column. The main advantages of the comprehensive approach are that

the entire sample (and not one or a few heart-cuts, as in conventional multidimensional GC (Dallüge *et al*., 2003) is subjected to a completely different separation, that the two-dimensional separation does not take any more time than the first-dimension run, and that the re-focusing in the modulator helps to increase analyte detectability. The most interesting additional benefit for CBs is, that structurally related as CB congeners show up as so-called ordered structures in the two-dimensional GC x GC plane. The very rapid second-dimension separation requires the use of detectors with sufficiently high data acquisition rates. Initially, only flame ionisation detectors could meet this requirement. However, today there is also a micro-ECD on the market that is widely used for GC x GC-µECD of halogenated compound classes. Even more importantly, analyte identification can be performed by using a time-of-flight mass spectrometer (Dallüge *et al*., 2002) or – with a modest loss of performance, but at a much lower price – one of the very recently introduced rapid-scanning quadrupole mass spectrometers (Korytar *et al*., 2005; Adahchour *et al*., 2005). So far, the use of GC x GC has been limited to qualitative applications and still seems inappropriate for routine quantification of analytes.

3 Quality assurance

Planners of monitoring programmes must decide on the accuracy, precision, repeatability, and limits of detection and determination which they consider acceptable. References of relevance to QA procedures include HELCOM, 1988; QUASIMEME 1992; Wells *et al*., 1992; Oehlenschläger, 1994; Smedes *et al.*, 1994 and ICES, 1996.

3.1 System performance

The performance of the GC system should be monitored by regularly checking the resolution of two closely eluting CBs. A decrease in resolution points to deteriorating GC conditions. The signal-to-noise ratio yields information on the condition of the detector. A dirty ECD detector or MS ion source can be recognised by the presence of an elevated background signal together with a reduced signal-to-noise ratio. Chromatograms should be inspected visually by a trained operator.

3.2 Recovery

The recovery should be checked and reported. One method is to add an internal (recovery) standard to each sample immediately before extraction and a second (quantification) standard immediately prior to injection. If smaller losses occur in extraction or clean-up, or solutions are concentrated by uncontrolled evaporation of solvents (*e.g.* because vials are not perfectly capped), such losses can be compensated for by normalisation. If major losses are recognised and the reasons are unknown, the results should not be reported, as recoveries are likely to be irreproducible. A control for the recovery standard is recommended by adding the calibration solution to a real sample. Recoveries should be between 70 and 120%, if not, analysis of samples should be repeated.

3.3 Blanks

A procedural blank should be measured for each sample series and should be prepared simultaneously using the same chemicals and solvents as for the samples. Its purpose is to indicate sample contamination by interfering compounds, which will lead to errors in quantification. Even if an internal standard has been added to the blank at the beginning of the procedure, a quantification of peaks in the blank and subtraction from the values obtained for the determinands must not be performed, as

the added internal standard cannot be adsorbed by a matrix. An alternative may be using a CB-free oil as a matrix blank.

3.4 Accuracy and precision

Analysis of a Laboratory Reference Material (LRM) should be included, at least one sample within each batch of samples. The LRM must be homogeneous, well characterised for the determinands in question and stability tests must have shown that it produces consistent results over time. The LRM should be of the same type of matrix (*e.g.* liver, muscle tissue, fat or lean fish) as the samples, and the determinant concentrations should occur in a comparable range to those of the samples. If the range of determinant concentrations in the sample is large (greater than a factor of 5) it is preferable to include two reference materials within each batch of analyses to cover the lower and upper concentrations. It is good practice to run duplicate analyses of a reference material to check within-batch analytical variability. A quality control chart should be recorded for a selected set of CBs. When introducing a new LRM or when it is suspected from the control chart that there is a systematic error possibly due to an alteration of the material, a relevant Certified Reference Material (CRM) of a similar matrix to the material analysed should be used to check the LRM. Additionally a duplicate of at least one sample should be run with every batch of samples. Each laboratory should participate in interlaboratory comparison studies and proficiency testing schemes on a regular basis, preferably at an international level.

3.5 Data collection and reporting

The calculation of results and the reporting of data can represent major sources of error. Control procedures should be established in order to ensure that data are correct and to obviate transcription errors. Data stored on databases should be checked and validated, and checks are also necessary when data are transferred between databases. If possible data should be reported in accordance with the latest ICES reporting formats.

HELCOM Manual for marine monitoring in the COMBINE programme

ANNEX B-12, APPENDIX 2. TECHNICAL NOTE ON THE DETERMINATION OF POLYCYCLIC AROMATIC HYDROCARBONS IN BIOTA

1. INTRODUCTION

Polycyclic aromatic hydrocarbons (PAHs) consist of a variable number of fused aromatic rings. By definition, PAHs contain at least three fused rings, although in practice related compounds with two fused rings (such as naphthalene and its alkylated derivatives) are often determined and will be considered in these guidelines. PAHs arise from incomplete combustion processes and from both natural and anthropogenic sources, although the latter generally predominate. PAHs are also found in oil and oil products, and these include a wide range of alkylated PAHs formed as a result of diagenetic processes, whereas PAHs from combustion sources comprise mainly parent (non-alkylated) PAHs. PAHs are of concern in the marine environment for two main reasons: firstly, low-molecular weight (MW) PAHs can be directly toxic to marine animals; secondly, metabolites of some of the high-MW PAHs are potent animal and human carcinogens, benzo[a]pyrene is the prime example. Carcinogenic activity is closely related to structure, however, and benzo[e]pyrene and four benzofluoranthene isomers (all six compounds have a molecular weight of 252 Da) are much less potent. Some compounds (e.g., heterocyclic compounds containing sulphur, such as benzothiophenes and dibenzo-thiophenes) may also cause taint in commercially exploited fish and shellfish and render them unfit for sale.
PAHs are readily taken up by marine animals both across gill surfaces and from their diet, and may bioaccumulate, particularly in shellfish. Filter-feeding organisms such as bivalve molluscs can accumulate high concentrations of PAHs, both from chronic discharges to the sea (e.g., of sewage) and following oil spills. Fish are exposed to PAHs both via uptake across gill surfaces and from their diet, but do not generally accumulate high concentrations of PAHs as they possess an effective mixed-function oxygenase (MFO) system which allows them to metabolize PAHs and to excrete them in bile. An assessment of the exposure of fish to PAHs therefore requires also the determination of PAH-metabolite concentrations in bile samples, as turnover times can be extremely rapid. Thus, the analysis of PAHs in fish muscle tissue should normally only be undertaken for food quality assurance purposes (Law and Biscaya, 1994).

There are marked differences in the behaviour of PAHs in the aquatic environment between the low-MW compounds (such as naphthalene; 128 Da) and the high-MW compounds (such as benzo[ghi]perylene; 276 Da) as a consequence of their differing physico-chemical properties. The low-MW compounds are appreciably water soluble and can be bioaccumulated from the "dissolved" phase by transfer across gill surfaces, whereas the high-MW compounds are relatively insoluble and hydrophobic, and can attach to both organic and inorganic particulates within the water column. PAHs derived from combustion sources may actually be deposited to the sea already adsorbed to atmospheric particulates, such as soot particles. The majority of PAHs in the water column will eventually be either taken up by biota or transported to the sediments, and deep-water depositional areas may generally be regarded as sinks for PAHs, particularly when they are anoxic.

2. APPROPRIATE SPECIES FOR ANALYSIS OF PAHS

2.1 Benthic fish and shellfish

All teleost fish have the capacity for rapid metabolism of PAHs, thereby limiting their usefulness for monitoring temporal or spatial trends of PAHs. Shellfish (particularly molluscs) generally

have a lesser metabolic capacity towards PAHs, and so they are preferred because PAH concentrations are generally higher in their tissues.

For the purposes of temporal trend monitoring, it is essential that long time series with either a single species or a limited number of species are obtained. Care should be taken that the sample is representative of the population and that sampling can be repeated annually. There are advantages in the use of molluscs for this purpose as they are sessile, and so reflect the degree of contamination in the local area to a greater degree than fish which are mobile. The analysis of fish tissues is often undertaken in conjunction with biomarker and disease studies, and associations have been shown between the incidence of some diseases (e.g., liver neoplasia) in flatfish and the concentrations of PAHs in the sediments over which they live and feed (Malins et al., 1988; Vethaak and ap Rheinallt, 1992). The exposure of fish to PAHs can be assessed by the analysis of PAH-metabolites in bile, and by measuring the induction of mixed-function oxygenase enzymes which affect the formation of these metabolites. At offshore locations, the collection of appropriate shellfish samples may be problematic if populations are absent, sparse or scattered, and the collection of fish samples may be simpler. Generally, the analysis of PAHs in fish muscle tissue should only be considered for the purposes of food quality assurance.

Recent monitoring studies have indicated a seasonal cycle in PAH concentrations (particularly for combustion-derived PAHs) in mussels, with maximum concentrations in the winter prior to spawning and minimum concentrations in the summer. It is particularly important, therefore, that samples selected for trend monitoring and spatial comparisons are collected at the same time of year, and preferably in the first months of the year before spawning.

2.2 Fish

Fish are not recommended for spatial or temporal trend monitoring of PAHs, but can be useful as part of biological effects studies or for food quality assurance purposes. The sampling strategy for biological effects monitoring is described in the OSPAR Joint Assessment and Monitoring Programme (JAMP).

3. TRANSPORTATION

Live mussels should be transported to the laboratory for sample preparation. They should be transported in closed containers at temperatures between 5 °C and 15 °C, preferably below 10 °C. For live animals it is important that the transport time is short and controlled (e.g., maximum of 24 hours).

Fish samples should be kept cool or frozen (at a temperature of -20 °C or lower) as soon as possible after collection. Frozen fish samples should be transported in closed containers at temperatures below -20 °C. If biomarker determinations are to be made, then it will be necessary to store tissue samples at lower temperatures, for example, in liquid nitrogen at -196 °C.

4. PRETREATMENT AND STORAGE

4.1 Contamination

Sample contamination may occur during sampling, sample handling, pretreatment and analysis, due to the environment, the containers or packing materials used, the instruments used during sample preparation, and from the solvents and reagents used during the analytical procedures. Controlled conditions are therefore required for all procedures, including the dissection of fish organs on-board a ship (see ANNEX B-13, Appendix 1). In the case of PAHs, particular care must be taken to avoid contamination at sea. On ships there are multiple sources of PAHs, such as the

oils used for fuel and lubrication, and the exhaust from the ship's engines. It is important that the likely sources of contamination are identified and steps taken to preclude sample handling in areas where contamination can occur. A ship is a working vessel and there can always be procedures occurring as a result of the day-to-day operations (deck cleaning, automatic overboard bilge discharges, etc.) which could affect the sampling process. One way of minimizing the risk is to conduct dissection in a clean area, such as within a laminar-flow hood away from the deck areas of the vessel. It is also advisable to collect samples of the ship's fuel, bilge water, and oils and greases used on winches, etc., which can be used as fingerprinting samples at a later date, if there are suspicions of contamination in particular instances.

4.2 Shellfish

4.2.1 Depuration

Depending upon the situation, it may be desirable to depurate shellfish so as to void the gut contents and any associated contaminants before freezing or sample preparation. This is usually applied close to point sources, where the gut contents may contain significant quantities of PAHs associated with food and sediment particles which are not truly assimilated into the tissues of the mussels. Depuration should be undertaken under controlled conditions and in filtered sea water; depuration over a period of 24 hours is usually sufficient. The aquarium should be aerated and the temperature and salinity of the water should be similar to that from which the animals were removed.

4.2.2 Dissection and storage

When samples are processed, both at sea and onshore, the dissection must be undertaken by trained personnel on a clean bench wearing clean gloves and using clean stainless steel knives and scalpels. Stainless steel tweezers are recommended for holding tissues during dissection. After each sample has been prepared, all tools and equipment (such as homogenizers) should be cleaned.

4.3 Fish

4.3.1 Dissection and storage

The dissection of fish muscle and internal organs should be carried as soon as possible after collection. The details of fish muscle and liver dissection are given in ANNEX B-13, Appendix 1. If possible, the entire right side dorsal lateral fillet should be homogenized and sub samples taken for replicate PAH determinations. If, however, the amount of material to be homogenized would be too large, a specific portion of the dorsal musculature should be chosen. It is recommended that the portion of the muscle lying directly under the first dorsal fin is used in this case.

When dissecting the liver, care should be taken to avoid contamination from the other organs. If bile samples are to be taken for PAH-metabolite determinations, then they should be collected first. If the whole liver is not to be homogenized, a specific portion should be chosen in order to ensure comparability. Freeze-drying of tissue samples cannot be recommended for PAH determination, due to the contamination which may result from back-streaming of oil from the rotary pumps used to generate the vacuum.

If plastic bags or boxes are used, then they should be used as outer containers only, and should not come into contact with tissues. Organ samples (e.g., livers) should be stored in pre-cleaned containers made of glass, stainless steel or aluminium, or should be wrapped in pre-cleaned aluminium foil and shock-frozen quickly in liquid nitrogen or in a blast freezer. In the latter case, care should be taken that the capacity of the freezer is not exceeded (Law and de Boer,

1995). Cold air should be able to circulate between the samples in order that the minimum freezing time can be attained (maximum 12 hours). The individual samples should be clearly and indelibly labelled and stored together in a suitable container at a temperature of -20 °C until analysis. If the samples are to be transported during this period (e.g., from the ship to the laboratory), then arrangements must be made which ensure that the samples do not thaw out during transport. Sub samples for biomarker determinations should be collected immediately after death in order to minimize post-mortem changes in enzymatic and somatic activities, and stored in suitable vials in liquid nitrogen until analysis.

When samples are processed, both at sea and onshore, the dissection must be undertaken by trained personnel on a clean bench wearing clean gloves and using clean stainless steel knives and scalpels. Stainless steel tweezers are recommended for holding tissues during dissection. After each sample has been prepared, all tools and equipment (such as homogenizers) should be cleaned.

When pooling of tissues is necessary, an equivalent quantity of tissue should be taken from each fish, e.g., 10 % from each whole fillet.

5. ANALYSIS

5.1 Preparation of materials

Solvents, reagents, and adsorptive materials must be free of PAHs and other interfering compounds. If not, then they must be purified using appropriate methods. Reagents and absorptive materials should be purified by solvent extraction and/or by heating in a muffle oven, as appropriate. Glass fibre materials (e.g., Soxhlet thimbles) are preferred over filter papers and should be cleaned by solvent extraction. It should be borne in mind that clean materials can be re-contaminated by exposure to laboratory air, particularly in urban locations, and so storage after cleaning is of critical importance. Ideally, materials should be prepared immediately before use, but if they are to be stored, then the conditions should be considered critically. All containers which come into contact with the sample should be made of glass, and should be pre-cleaned before use. Appropriate cleaning methods would include washing with detergents, rinsing with water, and finally solvent-rinsing immediately before use. Heating of glassware in an oven (e.g., at 400°C for 24 hours) can also be useful in removing PAH contamination.

5.2 Lipid determination

Although PAH data are not usually expressed on a lipid basis, the determination of the lipid content of tissues can be of use in characterizing the samples. The lipid content should be determined on a separate subsample of the tissue homogenate, as some of the extraction techniques used routinely for PAH determination (e.g., alkaline saponification) destroy lipid materials. The total fat weight should be determined using the method of Smedes (1999) or an equivalent method.

5.3 Dry weight determination

Generally PAH data are expressed on a wet weight basis, but sometimes it can be desirable to consider them on a dry weight basis. Again, the dry weight determination should be conducted on a separate sub sample of the tissue homogenate, which should be air-dried to constant weight at 105 °C.

5.4 Extraction and clean-up

PAHs are lipophilic and so are concentrated in the lipids of an organism, and a number of methods have been described for PAH extraction (see, e.g., Ehrhardt *et al.,* 1991). The preferred methods generally utilize either Soxhlet extraction, or alkaline digestion followed by liquid-liquid extraction with an organic solvent. Microwave-assisted solvent extraction can be mentioned as one of the modern techniques being applied to PAH analysis (Budzinski *et al.,* 2000; During and Gaath, 2000; Vázquez Blanco *et al*., 2000; Ramil Criado *et al.,* 2002). In the case of Soxhlet extraction, the wet tissue must be dried by mixing with a chemical agent (e.g., anhydrous sodium sulphate), in which case a time period of several hours is required between mixing and extraction in order to allow complete binding of the water in the sample. Alkaline digestion is conducted on wet tissue samples, so this procedure is unnecessary. In neither case can the freeze-drying of the tissue prior to extraction be recommended, owing to the danger of contamination from oil back-streaming from the rotary pump (which provides the vacuum) into the sample. Non-polar solvents alone will not effectively extract all the PAHs from tissues when using Soxhlet extraction, and mixtures such as hexane/dichloromethane may be effective in place of solvents such as benzene and toluene, used historically for this purpose. Alkaline digestion has been extensively used in the determination of PAHs and hydrocarbons and is well documented. It is usually conducted in alcohol (methanol or ethanol), which should contain at least 10 % water, and combines disruption of the cellular matrix, lipid extraction and saponification within a single procedure, thereby reducing sample handling and treatment. For these reasons, it should be the method of choice. Solvents used for liquid-liquid extraction of the homogenate are usually non-polar, such as pentane or hexane, and they will effectively extract all PAHs.

Tissue extracts will always contain many compounds other than PAHs, and a suitable clean-up is necessary to remove those compounds which may interfere with the subsequent analysis. Different techniques may be used, both singly or in combination, and the choice will be influenced by the selectivity and sensitivity of the final measurement technique and also by the extraction method employed. If Soxhlet extraction was used, then there is a much greater quantity of residual lipid to be removed before the analytical determination can be made than in the case of alkaline digestion. An additional clean-up stage may therefore be necessary. The most commonly used clean-up methods involve the use of alumina or silica adsorption chromatography, but gel permeation chromatography and similar high performance liquid chromatography (HPLC) based methods are also employed (Nondek *et al.,* 1993; Nyman *et al.,* 1993; Perfetti *et al.,*1992). The major advantages of using HPLC-based clean-up methods are their ease of automation and reproducibility.

5.5 Pre-concentration

The sample volume should be 2 cm^3 or greater to avoid errors when transferring solvents during the clean-up stages. Evaporation of solvents using a rotary-film evaporator should be performed at low temperature (water bath temperature of 30 °C or lower) and under controlled pressure conditions, in order to prevent losses of the more volatile PAHs such as naphthalenes. For the same reasons, evaporation to dryness should be avoided. When reducing the sample to final volume, solvents can be removed by a stream of clean nitrogen gas. Suitable solvents for injection into the gas chromatograph (GC) or GC-MS include pentane, hexane, heptane and *iso*-octane, whereas for HPLC analyses acetonitrile and methanol are commonly used.

5.6 Selection of PAHs to be determined

The choice of PAHs to be analysed is not straightforward, both because of differences in the range of PAH compounds resulting from combustion processes and from oil and oil products, and also because the aims of specific monitoring programmes can require the analysis of different representative groups of compounds. PAHs arising from combustion processes are predominantly parent (unsubstituted) compounds, whereas oil and its products contain a much

wider range of alkylated compounds in addition to the parent PAHs. This has implications for the analytical determination, as both HPLC-based and GC-based techniques are adequate for the determination of a limited range of parent PAHs in samples influenced by combustion processes, whereas in areas of significant oil contamination and following oil spills only GC-MS has sufficient selectivity to determine the full range of PAHs present. The availability of pure individual PAHs for the preparation of standards is problematic and limits both the choice of determinands and, to some degree, the quantification procedures which can be used. The availability of reference materials certified for PAHs is also rather limited. A list of target parent and alkylated PAHs suitable for environmental monitoring is given in Table 1. In both cases, the list was concentrated on a subset of parent (predominantly combustion-derived) PAHs due to analytical limitations. This approach completely neglects the determination of alkylated PAHs, which allows the interpretation of PAH accumulation from multiple sources including those due to oil inputs. It will not be necessary for all of these PAH compounds and groups to be analysed in all cases, but an appropriate selection can be made from this list depending on the specific aims of the monitoring programme to be undertaken.

Table 1: Compounds of interest for environmental monitoring for which the guidelines apply

Compound	**MW**	**Compound**	**MW**
Naphthalene	128	C2-Phenanthrenes/Anthracenes	206
C1-Naphthalenes	142	C3-Phenanthrenes/Anthracenes	220
C2-Naphthalenes	156	Fluoranthene	202
C3-Naphthalenes	170	Pyrene	202
C4-Naphthalenes	184	C1-Fluoranthenes/Pyrenes	216
Acenaphthylene	152	C2-Fluoranthenes/Pyrenes	230
Acenaphthene	154	Benz[a]anthracene	228
Biphenyl	154	Chrysene	228
Fluorene	166	2,3-Benzanthracene	228
C1-Fluorenes	180	Benzo[a]fluoranthene	252
C2-Fluorenes	194	Benzo[b]fluoranthene	252
C3-Fluorenes	208	Benzo[j]fluoranthene	252
Dibenzothiophene	184	Benzo[k]fluoranthene	252
C1-Dibenzothiophenes	198	Benzo[e]pyrene	252
C2-Dibenzothiophenes	212	Benzo[a]pyrene	252
C3-Dibenzothiophenes	226	Perylene	252
Phenanthrene	178	Indeno[1,2,3-cd]pyrene	276
Anthracene	178	Benzo[ghi]perylene	276
C1-Phenanthrenes/ Anthracenes	192	Dibenz[ah]anthracene	278

5.7 Instrumental determination of PAHs

Unlike the situation for chlorobiphenyls (CBs), where GC techniques (particularly GC-ECD) are used exclusively, two major approaches based on GC and HPLC are followed to an equal extent in the analysis of PAHs. The greatest sensitivity and selectivity in routine analyses are achieved by combining HPLC with fluorescence detection (HPLC-UVF) and capillary gas chromatography with mass spectrometry (GC-MS). In terms of flexibility, GC-MS is the most capable technique, as in principle it does not limit the selection of determinands in any way, while HPLC is suited only to the analysis of parent PAHs. In the past, analyses have also been conducted using HPLC with UV-absorption detection and GC with flame-ionization detection, but neither can be recommended because of their relatively poor selectivity.

Intercomparison exercises have demonstrated a serious lack of comparability between specific hydrocarbon concentrations measured in different laboratories and using both analytical approaches described above (Farrington *et al.,* 1986). An interlaboratory performance study has been carried out within the QUASIMEME laboratory testing scheme in order to assess the level of comparability among laboratories conducting PAH analyses and to identify improvements in methodology (Law and Klungsøyr, 1996; Law *et al.,* 1998, QUASIMEME). Limits of determination within the range of 0.2 to 10 μg kg-1 wet weight for individual PAH compounds should be achievable by both GC-MS and HPLC-UVF techniques.

5.8 HPLC

Reversed-phase columns (e.g., octadecylsilane (RP-18)) 15–30 cm in length are used almost exclusively, in conjunction with gradient elution using mixtures of acetonitrile/water or methanol/water. A typical gradient may start as a 50 % mixture, changing to 100 % acetonitrile or methanol in 40 minutes. This flow is maintained for 20 minutes, followed by a return to the original conditions in 5 minutes and 5–10 minutes' equilibration before the next injection. The use of an automatic injector is strongly recommended. Also, the column should be maintained in a column oven heated to 10–30°C. The systems yielding the best sensitivity and selectivity utilize fluorescence detection. As different PAH compounds yield their maximum fluorescence at different wavelengths, for optimum detection of PAHs the wavelengths of the detector should be programmed so that the excitation/emission wavelengths detected are changed at pre-set times during the analytical determination. For closely eluting peaks, it may be necessary to use two detectors in series utilizing different wavelength pairs, or to affect a compromise in the selected wavelengths if a single detector is used. As the fluorescence signals of some PAHs (e.g., pyrene) are quenched by oxygen, the eluents must be degassed thoroughly. This is usually achieved by continuously bubbling a gentle stream of helium through the eluent reservoirs, but a vacuum degasser can also be used. Polytetrafluorethylene (PTFE) tubing must not then be used downstream of the reservoirs as this material is permeable to oxygen; stainless steel or polyether-etherketone (PEEK) tubing is preferred.

5.9 GC-MS

The two injection modes commonly used are splitless and on-column injection. Automatic sample injection should be used wherever possible to improve the reproducibility of injection and the precision of the overall method. If splitless injection is used, the liner should be of sufficient capacity to contain the injected solvent volume after evaporation. For PAH analysis, the cleanliness of the liner is also very important if adsorption effects and discrimination are to be avoided, and the analytical column should not contain active sites to which PAHs can be adsorbed. Helium is the preferred carrier gas, and only capillary columns should be used. Because of the wide boiling range of the PAHs to be determined and the surface-active properties of the higher PAHs, the preferred column length is 25–30 m, with an internal diameter of 0.15 mm to 0.3 mm. Film thicknesses of 0.3 μm to 1 μm are generally used; this choice has little impact on critical resolution, but thicker films are often used when one-ring aromatic compounds are to be determined alongside PAHs, or where a high sample loading is

needed. No stationary phase has been found on which all PAH isomers can be resolved; the most commonly used stationary phase for PAH analysis is 5 % phenyl methylsilicone (DB-5 or equivalent). This will not, however, resolve critical isomers such as benzo[*b*], [*j*] and [*k*]fluoranthenes, or chrysene from triphenylene. These separations can be made on other columns, if necessary. For PAHs there is no sensitivity gain from the use of chemical ionization (either positive or negative ion), so analyses are usually conducted in electron-impact mode at 70 eV. The choice of full-scan or multiple-ion detection is usually made in terms of sensitivity. Some instruments such as ion-trap mass spectrometers exhibit the same sensitivity in both modes, so full-scan spectra are collected, whereas for quadrupole instruments greater sensitivity is obtained if the number of ions scanned is limited. In that case, the masses to be detected are programmed to change during the analysis as different PAHs elute from the capillary column.

6. CALIBRATION AND QUANTIFICATION

6.1 Standards

A range of fully deuterated parent PAHs is available for use as standards in PAH analysis. The availability of pure PAH compounds is limited (Annex B-7). Although most of the parent compounds can be purchased as pure compounds, the range of possible alkyl-substituted PAHs is vast and only a limited selection of them can be obtained. In HPLC, where the resolving power of the columns is limited and the selectivity less than that which can be obtained using MS detection, only a single internal standard is normally used (e.g., phenanthrene-d10), although fluoranthene-d10 and 6-methyl chrysene, among others, have also been used. If GC-MS is used, then a wider range of deuterated PAHs can be utilized, both because of the wide boiling range of PAHs present and because that allows the use of both recovery and quantification standards. Suitable standards could range from naphthalene-d8 to perylene-d10. It is always recommended to use at least two and preferably three internal standards of hydrocarbons of small, medium, and high molecular weight (e.g., naphthalene-d8, phenanthrene-d10, perylene-d12. Crystalline PAHs of known purity should be used for the preparation of calibration standards. If the quality of the standard materials is not guaranteed by the producer or supplier (as for certified reference materials), then it should be checked by GC-MS analysis. Solid standards should be weighed to a precision of 10-5 grams. Calibration standards should be stored in the dark because some PAHs are photosensitive, and ideally solutions to be stored should be sealed in amber glass ampoules. Otherwise, they can be stored in a refrigerator in stoppered measuring cylinders or flasks that are gas tight to avoid evaporation of the solvent during storage.

6.2 Calibration

Multilevel calibration with at least five calibration levels is preferred to adequately define the calibration curve. In general, GC-MS calibration is linear over a considerable concentration range but exhibits non-linear behaviour when the mass of a compound injected is low due to adsorption. Quantification should be conducted in the linear region of the calibration curve, or the non-linear region must be well characterized during the calibration procedure. For HPLC-UVF, the linear range of the detection system should be large, and quantification should be made within the linear range. External standardization is often used with HPLC due to the relatively limited resolution obtainable with this technique as generally employed.

6.3 Recovery

The recovery of analytes should be checked and reported. Given the wide boiling range of the PAHs to be determined, the recovery may vary with compound group, from the volatile PAHs of low molecular weight to the larger compounds. For GC-MS analysis, deuterated standards can

be added in two groups: those to be used for quantification are added at the start of the analytical procedure, whilst those from which the absolute recovery will be assessed are added prior to GC-MS injection. This ensures that the calculated PAH concentrations are corrected for the recovery obtained in each case. In the case of HPLC, where only a single deuterated PAH standard is used, it is more common to assess recovery periodically by carrying a standard solution through the whole analytical procedure, then assessing recovery by reference to an external standard. This technique does not, however, correct for matrix effects, and so may be used in conjunction with the spiking of real samples.

7. ANALYTICAL QUALITY CONTROL

Planners of monitoring programmes must decide on the accuracy, precision, repeatability, and limits of detection and determination which they consider acceptable. Achievable limits of determination for each individual component are as follows:

- for GC-MS measurements: 0.2 µg kg-1 ww;
- for HPLC measurements: 0.5–10 µg kg-1 ww.

Further information on analytical quality control procedures for PAHs can be found elsewhere (Law and de Boer, 1995). A procedural blank should be measured with each sample batch, and should be prepared simultaneously using the same chemical reagents and solvents as for the samples. Its purpose is to indicate sample contamination by interfering compounds, which will result in errors in quantification. The procedural blank is also very important in the calculation of limits of detection and limits of quantification for the analytical method. In addition, a laboratory reference material (LRM) should be analysed within each sample batch. Test materials from the former runs of QUASIMEME Laboratory Proficiency Testing can be used as Laboratory Reference Material. The LRM must be homogeneous and well characterized for the determinands of interest within the analytical laboratory. Ideally, stability tests should have been undertaken to show that the LRM yields consistent results over time. The LRM should be of the same matrix type (e.g., liver, muscle, mussel tissue) as the samples, and the determinand concentrations should be in the same range as those in the samples. Realistically, and given the wide range of PAH concentrations encountered, particularly in oil spill investigations, this is bound to involve some compromise. The data produced for the LRM in successive sample batches should be used to prepare control charts. It is also useful to analyse the LRM in duplicate from time to time to check within-batch analytical variability. The analysis of an LRM is primarily intended as a check that the analytical method is under control and yields acceptable precision, but a certified reference material (CRM) of a similar matrix should be analysed periodically in order to check the method bias. The availability of biota CRMs certified for PAHs is very limited (Annex B-7; QUASIMEME), and in all cases the number of PAHs for which certified values are provided is small. At regular intervals, the laboratory should participate in an intercomparison or proficiency exercise in order to provide an independent check on the performance.

8. DATA REPORTING

The calculation of results and the reporting of data can represent major sources of error, as has been shown in intercomparison studies for PAHs. Control procedures should be established in order to ensure that data are correct and to obviate transcription errors. Data stored in databases should be checked and validated, and checks are also necessary when data are transferred between databases. Data should be reported in accordance with the latest ICES reporting formats.

CEMP Guidelines for Monitoring Contaminants in Biota
(OSPAR Agreement 1999-02)
Technical Annex 3: Determination of parent and alkylated PAHs in biological materials

CEMP Guidelines for Monitoring Contaminants in Biota

(OSPAR Agreement 1999-02)

Technical Annex 3: Determination of parent and alkylated PAHs in biological materials

1. Introduction

Polycyclic aromatic hydrocarbons (PAHs) consist of a variable number of fused benzene rings. By definition, PAHs contain at least two fused rings. PAHs arise from incomplete combustion processes and from both natural and anthropogenic sources, although the latter generally predominate. PAHs are also found in oil and oil products, and these include a wide range of alkylated PAHs formed as a result of diagenetic processes, whereas PAHs from combustion sources comprise mainly parent (non-alkylated) compounds. PAHs are of concern in the marine environment for two main reasons: firstly, low molecular weight (MW) PAHs can cause tainting of fish and shellfish and render them unfit for sale; secondly, metabolites of some of the high MW PAHs are potent animal and human carcinogens — benzo[*a*]pyrene is the prime example. Carcinogenic activity is closely related to structure. Benzo[*e*]pyrene and the four benzofluoranthene isomers all have a molecular weight of 252 Da; however, they are much less potent than benzo[*a*]pyrene. Less is known about toxicity of alkylated PAHs. However, one study has demonstrated that alkylated PAHs may have increased toxicity compared to the parent compound (Marvanova *et al.,* 2008).

PAHs are readily taken up by marine animals both across gill surfaces (lower MW PAHs) and from their diet. They may bioaccumulate, particularly in shellfish. Filter-feeding organisms such as bivalve molluscs can accumulate high concentrations of PAHs, both from chronic discharges to the sea (e.g., of sewage) and following oil spills. Fish are exposed to PAHs both via uptake across gill surfaces and from their diet, but do not generally accumulate high concentrations of PAHs as they possess an effective mixed-function oxygenase (MFO) system which allows them to metabolise PAHs and to excrete them in bile. Other marine vertebrate and marine mammals also metabolise PAHs efficiently. An assessment of the exposure of fish to PAHs therefore requires the determination of PAH metabolite concentrations in bile, as turnover times can be extremely rapid.

There are marked differences in the behaviour of PAHs in the aquatic environment between the low MW compounds (such as naphthalene; 128 Da) and the high MW compounds (such as benzo[*ghi*]perylene; 276 Da) as a consequence of their differing physico-chemical properties. The low MW compounds are appreciably water soluble (e.g. naphthalene) and can be bioaccumulated from the dissolved phase by transfer across gill surfaces, whereas the high MW compounds are relatively insoluble and hydrophobic, and can attach to both organic and inorganic particulates within the water column. PAHs derived from combustion sources may actually be deposited to the sea already

adsorbed to atmospheric particulates, such as soot particles. The sediment will act as a sink for PAHs in the marine environment.

2. Appropriate species for analysis of parent and alkylated PAHs

2.1 Benthic fish and shellfish

Guidance on the selection of appropriate species for contaminant monitoring is given in the OSPAR Joint Assessment and Monitoring Programme guidelines. All teleost fish have the capacity for rapid metabolism of PAHs, thereby limiting their usefulness for monitoring temporal or spatial trends of PAHs. Shellfish (particularly molluscs) generally have a lesser metabolic capacity towards PAHs, and so they are preferred because PAH concentrations are generally higher in their tissues. The blue mussel (*Mytilus edulis*) occurs in shallow waters along almost all coasts of the Northeast Atlantic. It is therefore suitable for monitoring in near shore waters. No distinction is made between *M. edulis* and *M. galloprovincialis* because the latter species, which may occur along Spanish and Portuguese coasts, fills a similar ecological niche. A sampling size range of 30–70 mm shell length is specified to ensure availability throughout the whole maritime area. In some areas (e.g., the Barents Sea), other species may be considered. Recent monitoring studies have indicated a seasonal cycle in PAH concentrations (particularly for combustion-derived PAHs) in mussels, with maximum concentrations in the winter prior to spawning and minimum concentrations in the summer. It is particularly important, therefore, that samples selected for trend monitoring and spatial comparisons are collected at the same time of year, and preferably in the first months of the year prior to spawning.

For the purposes of temporal trend monitoring, it is essential that long time-series with either a single species or a limited number of species be obtained. Care should be taken that the sample is representative of the population and that it can be sampled annually. There are advantages in the use of molluscs for this purpose as they are sessile, and so reflect the degree of contamination in the local area to a greater degree than fish which are mobile and metabolise PAHs relatively efficiently. The analysis of fish tissues is often undertaken in conjunction with biomarker and disease studies, and associations have been shown between the incidence of some diseases (e.g., liver neoplasia) in flatfish and the concentrations of PAHs in the sediments over which they live and feed (Malins *et al*., 1988; Vethaak and Rheinallt, 1992). The exposure of fish to PAHs can be assessed by the analysis of PAH metabolites in bile, and by measuring the induction of mixed-function oxygenase enzymes which catalyse the formation of these metabolites.

3. Transportation

Live biota should be transported in closed containers at temperatures between 5°C and 10°C. For live animals it is important that the transport time is short and controlled (e.g., maximum of 24 hours). If biomarker determinations are to be made, then it will be necessary to store tissue samples at lower temperatures, for example, in liquid nitrogen at -196°C.

4. Pre-treatment and storage

4.1 Contamination

Sample contamination may occur during sampling, sample handling, pre-treatment, and analysis, due to the environment, the containers or packing materials used, the instruments used during sample preparation, and from the solvents and reagents used during the analytical procedures. Controlled

conditions are therefore required for all procedures. In the case of PAHs, particular care must be taken to avoid contamination at sea. On ships there are multiple sources of PAHs, such as the oils used for fuel and lubrication, and the exhaust from the ship's engines. It is important that the likely sources of contamination are identified and steps taken to preclude sample handling in areas where contamination can occur. A ship is a working vessel and there can always be procedures occurring as a result of the day-to-day operations (deck cleaning, automatic overboard bilge discharges, etc.) which could affect the sampling process. One way of minimizing the risk is to conduct dissection in a clean area, such as within a laminar-flow hood away from the deck areas of the vessel. It is also advisable to collect samples of the ship's fuel, bilge water, and oils and greases used on winches, etc., which can be used as fingerprinting samples at a later date, if there are suspicions of contamination in particular instances.

Freeze-drying of tissue samples may be a source of contamination due to the back-streaming of oil vapours from the rotary vacuum pumps. Furthermore, drying the samples may result in losses of the lower molecular weight and more volatile PAHs through evaporation (Law and Biscaya, 1994).

4.2 Shellfish

4.2.1 Depuration

Depending upon the situation, it may be desirable to depurate shellfish so as to void the gut contents and any associated contaminants before freezing or sample preparation. This is usually applied close to point sources, where the gut contents may contain significant quantities of PAHs associated with food and sediment particles which are not truly assimilated into the tissues of the mussels. Depuration should be undertaken in controlled conditions and in clean seawater; depuration over a period of 24 hours is usually sufficient. The aquarium should be aerated and the temperature and salinity of the water should be similar to that from which the animals were removed.

4.2.2 Dissection and storage

Mussels should be shucked live and opened with minimal tissue damage by detaching the adductor muscles from the interior of at least one valve. The soft tissues should be removed and homogenised as soon as possible, and frozen in glass jars or aluminium cans at –20°C until analysis. Plastic materials must not be used for sampling and storage owing to possible adsorption of the PAHs onto the container material. As PAHs are sensitive to photo-degradation, exposure to direct sunlight or other strong light must be avoided during storage of the samples as well as during all steps of sample preparation, including extraction and storage of the extracts (Law and Biscaya, 1994). The use of amber glassware is strongly recommended.

When samples are processed, both at sea and onshore, the dissection must be undertaken by trained personnel on a clean bench wearing clean gloves and using PAH-free stainless steel knives and scalpels. Stainless steel tweezers are recommended for holding tissues during dissection. After each sample has been prepared, all tools and equipment (such as homogenisers) should be cleaned by wiping with tissue and rinsing with solvent.

5. Analysis

5.1 Preparation of materials

Solvents and adsorptive materials must all be checked for the presence of PAHs and other interfering compounds. If found then the solvents, reagents, and adsorptive materials must be purified or cleaned using appropriate methods. Absorptive materials should be cleaned by solvent extraction and/or by heating in a muffle oven as appropriate. Glass fibre materials (e.g. Soxhlet thimbles and filter papers used in pressurised liquid extraction (PLE)) should be cleaned by solvent extraction or pre-baked at 450°C overnight. It should be borne in mind that clean materials can be re-contaminated by exposure to laboratory air, particularly in urban locations, and so the method of storage after cleaning is of critical importance. Ideally, materials should be prepared immediately before use, but if they are to be stored, then the conditions should be considered critically. All containers which come into contact with the sample should be made of glass or aluminium, and should be pre-cleaned before use. Appropriate cleaning methods would include washing with detergents, rinsing with water of known quality, and finally solvent rinsing immediately before use.

5.2 Lipid determination

Although PAH data are not usually expressed on a lipid basis, the determination of the lipid content of tissues can be of use in characterising the samples. This will enable reporting concentrations on a wet weight or lipid weight basis. The lipid content should be determined on a separate subsample of the tissue homogenate, as some of the extraction techniques used routinely for PAHs determination (e.g., PLE with fat retainers, alkaline saponification) destroy or remove lipid materials. The total lipid content of fish or shellfish should be determined using the method of Bligh and Dyer (1959) as modified by Hanson and Olley (1963) or an equivalent method such as Smedes (1999). Extractable lipid may be used, particularly if the sample size is small and lipid content is high. It has been shown that if the lipid content is high (>5%) then extractable lipid will be comparable to the total lipid.

5.3 Extraction

PAHs are lipophilic and so are concentrated in the lipids of an organism, and a number of methods have been described for PAH extraction (Ehrhardt *et al*., 1991). These methods generally utilise either Soxhlet extraction, or alkaline digestion followed by liquid-liquid extraction with an organic solvent. In the case of Soxhlet extraction, the wet tissue must be dried by mixing with a chemical drying agent (e.g., anhydrous sodium sulphate), in which case a time period of several hours is required between mixing and extraction in order to allow complete binding of the water in the sample. Samples are spiked with recovery standard and should be left overnight to equilibrate. Alkaline digestion is conducted on wet tissue samples, so this procedure is unnecessary.

Apolar solvents alone will not effectively extract all the PAHs from tissues when using Soxhlet extraction, and mixtures such as hexane/dichloromethane may be effective in place of solvents such as benzene and toluene, used historically for this purpose. Alkaline digestion has been extensively used in the determination of PAHs and hydrocarbons and is well documented. It is usually conducted in alcohol (methanol or ethanol), which should contain at least 10% water, and combines disruption of the cellular matrix, lipid extraction and saponification within a single procedure, thereby reducing sample handling and treatment. Solvents used for liquid-liquid extraction of the homogenate are usually apolar, such as pentane or hexane, and they will effectively extract all PAHs.

Alternatively extraction of wet or dry samples of biota may be carried out by pressurised liquid extraction (PLE). This is a more recent method, requiring less solvent and time for the extraction process. The wet biota sample is dried by mixing with sufficient anhydrous sodium sulphate to form a free flowing mixture and is packed into stainless steel extraction cells containing a glass fibre filter and sodium sulphate or glass powder to fill the cell. To ensure a better recovery samples may be extracted twice and extractions are performed at elevated temperatures and pressure.

5.4 Clean-up

Tissue extracts will always contain many compounds other than PAHs, and a suitable clean-up is necessary to remove those compounds which may interfere with the subsequent analysis. Different techniques may be used, either singly or in combination, and the choice will be influenced by the selectivity and sensitivity of the final measurement technique and also by the extraction method employed. If Soxhlet extraction was used, then there is a much greater quantity of residual lipid to be removed before the analytical determination can be made than in the case of alkaline digestion. An additional clean-up stage may therefore be necessary. The most commonly used clean-up methods involve the use of deactivated alumina or silica adsorption chromatography. When applying fractionation, the elution pattern has to be checked frequently. This should be carried out in the presence of sample matrix, as that can partially deactivate the clean-up column, resulting in earlier elution of the PAHs than in a standard solution.

Gel permeation chromatography (GPC) and high performance liquid chromatography (HPLC) based methods are also employed (Nondek *et al.,* 1993; Nyman *et al.,* 1993; Perfetti *et al.*, 1992). The major advantages of using HPLC-based clean-up methods are their ease of automation and reproducibility.

Isocratic HPLC fractionation of the extract can be used to give separate aliphatic and aromatic fractions (Webster *et al*., 2002). A metal-free silica column is used for the clean-up/fractionation as dibenzothiophene (DBT) can be retained on ordinary silica columns. The split time is determined by injection of a solution containing representative aliphatic and PAH standards. The silica column is regenerated by a cleaning cycle after a set number of samples. If PAHs are to be analysed by HPLC and there are significant amounts of alkylated PAHs present then the removal of the alkylated PAHs may be difficult.

5.5 Pre-concentration

In the methods suggested above, all result in an extract in which non-polar solvents are dominant. The sample volume should be 2 ml or greater to avoid errors when transferring solvents during the clean-up stages. Syncore parallel evaporators can be used with careful optimisation of the evaporation parameters. Evaporation of solvents using a rotary-film evaporator should be performed at low temperature (water bath temperature of 30°C or lower) and under controlled pressure conditions, in order to prevent losses of the more volatile PAHs such as naphthalenes. For the same reasons, evaporation to dryness must be avoided. When reducing the sample to final volume, solvents can be removed by a stream of clean nitrogen gas. Suitable solvents for injection into the GC-MS include pentane, hexane, heptane, *iso*-hexane and *iso*-octane.

5.6 Selection of PAHs to be determined

The choice of PAHs to be analysed is not straightforward, both because of differences in the range of PAH compounds resulting from combustion processes and from oil and oil products, and also because the aims of specific monitoring programmes can require the analysis of different representative

groups of compounds. PAHs arising from combustion processes are predominantly parent (unsubstituted) compounds, whereas oil and its products contain a much wider range of alkylated compounds in addition to the parent PAHs. This has implications for the analytical determination, as both HPLC-based and GC-based techniques are adequate for the determination of a limited range of parent PAHs in samples influenced by combustion processes, whereas in areas of significant oil contamination and following oil spills only GC-MS has sufficient selectivity to determine the full range of PAHs present. The availability of pure individual PAHs for the preparation of standards is problematic and limits both the choice of determinands and, to some degree, the quantification procedures which can be used. The availability of reference materials certified for PAHs is also rather limited. A list of target parent and alkylated PAHs suitable for environmental monitoring is given in Table A1.1. This differs both from the list previously developed within ICES specifically for intercomparison purposes, and the historic list of Borneff. In both cases, the lists were concentrated on a subset of parent (predominantly combustion-derived) PAHs due to analytical limitations. This approach completely neglects the determination of alkylated PAHs, which allows the interpretation of PAH accumulation from multiple sources including those due to oil inputs. It will not be necessary for all of these PAH compounds and groups to be analysed in all cases, but an appropriate selection can be made from this list depending on the specific aims of the monitoring programme to be undertaken.

Table A1.1: Compounds of interest for environmental monitoring for which the guidelines apply. For compounds in italics standards are not available for any isomers in this group.

Compound	MW	Compound	MW
Naphthalene	128	2, 3d-benzonapthothiophene	234
C_1-Naphthalenes	142	C_1-234	248
C_2-Naphthalenes	156	C_2-Fluoranthenes/Pyrenes	230
C_3-Naphthalenes	170	Benz[*a*]anthracene	228
C_4-Naphthalenes	184	Chrysene	228
Acenaphthylene	152	2,3-Benzanthracene	228
Acenaphthene	154	C_1- Benz[*a*]anthracene/ Chrysene	242
Biphenyl	154	C_2- Benz[*a*]anthracene/ Chrysene	256
Fluorene	166	C_3- Benz[*a*]anthracene/ Chrysene	270
C_1-Fluorenes	180	Benzo[*a*]fluoranthene	252
C_2-Fluorenes	*194*	Benzo[*b*]fluoranthene	252
C_3-Fluorenes	*208*	Benzo[*j*]fluoranthene	252
Dibenzothiophene	184	Benzo[*k*]fluoranthene	252
C_1-Dibenzothiophenes	198	Benzo[*e*]pyrene	252
C_2-Dibenzothiophenes	212	Benzo[*a*]pyrene	252
C_3-Dibenzothiophenes	226	Perylene	252
Phenanthrene	178	Indeno[1,2,3-*cd*]pyrene	276
Anthracene	178	Benzo[*ghi*]perylene	276
C_1-Phenanthrenes/Anthracenes	192	Dibenz[*a,h*]anthracene	278
C_2-Phenanthrenes/Anthracenes	206	Benzo[*k*]fluoranthene	252
C_3-Phenanthrenes/Anthracenes	220	Cyclopenta[*cd*]pyrene	226
Fluoranthene	202	Naphtho[2,1-*a*]pyrene	302
Pyrene	202	Dibenz[*a,e*]pyrene	302

C_1-Fluoranthenes/Pyrenes	216	Dibenz[*a,i*]pyrene	302
2, 1d-benzonapthothiophene	234	Dibenz[*a,l*]pyrene	302
1,2d-benzonapthothiophene	234	Dibenz[*a,h*]pyrene	302

5.7 Instrumental determination of PAHs

The greatest sensitivity and selectivity in routine analysis for parent PAH is achieved by combining HPLC with fluorescence detection (HPLC-UVF) or capillary gas chromatography with mass spectrometry (GC-MS). However, for the analysis of parent and alkylated PAHs GC-MS is the method of choice. In terms of flexibility, GC-MS is the most capable technique, as in principle it does not limit the selection of determinands in any way, while HPLC is suited only to the analysis of parent PAHs. In the past, analyses have also been conducted using HPLC with UV-absorption detection and GC with flame-ionisation detection, but neither can be recommended for alkylated PAHs because of their relatively poor selectivity. Both in terms of the initial capital cost of the instrumentation, and the cost per sample analysed, HPLC-UVF is cheaper than GC-MS. With the advent of high-sensitivity benchtop GC-MS systems, however, this cost advantage is now not as marked as in the past, and the additional information regarding sources available makes GC-MS the method of choice.

Limits of determination within the range of 0.05 to 0.5 µg kg^{-1} wet weight for individual PAH compounds should be achievable by GC-MS. However this limit can be lowered in routine analysis.

5.7.1 GC-MS

The three injection modes commonly used are splitless, on-column and PTV (programmed temperature vaporiser). Automatic sample injection should be used wherever possible to improve the reproducibility of injection and the precision of the overall method. If splitless injection is used, the liner should be of sufficient capacity to contain the injected solvent volume after evaporation. For PAH analysis, the cleanliness of the liner is also very important if adsorption effects and discrimination are to be avoided, and the analytical column should not contain active sites to which PAHs can be adsorbed. Helium is the preferred carrier gas, and only capillary columns should be used. Because of the wide boiling range of the PAHs to be determined and the surface-active properties of the higher PAHs, the preferred column length is 25–50 m, with an internal diameter of 0.15 mm to 0.3 mm. Film thicknesses of 0.2 µm to 1 µm are generally used; this choice has little impact on critical resolution, but thicker films are often used when one-ring aromatic compounds are to be determined alongside PAHs, or where a high sample loading is needed. No stationary phase has been found on which all PAH isomers can be resolved; the most commonly used stationary phase for PAH analysis is 5% phenyl methylsilicone (DB-5 or equivalent). This will not, however, resolve critical isomers such as benzo[*b*], [*j*] and [*k*]fluoranthenes, or chrysene from triphenylene. Chrysene and triphenylene can be separated on other columns, if necessary such as a 60 m non polar column such a DB5MS. For PAHs there is no sensitivity gain from the use of chemical ionisation (either positive or negative ion), so analyses are usually conducted in electron-impact mode at 70eV. Quadrupole instruments are used in single ion monitoring to achieve greater sensitivity. The masses to be detected are programmed to change during the analysis as different PAHs elute from the capillary column. In SIM the molecular ion is used for quantification. Qualifier ions can be used to confirm identification but they are limited for PAHs. Triple quadropole mass spectrometry can also be used and will give greater sensitivity. Some instruments such as ion-trap and time of flight mass spectrometers exhibit the same sensitivity in both modes, so full scan spectra can be used for quantification.

An example of mass spectrometer operating conditions in SIM mode is given in Table A1.2. The ions are grouped and screened within GC time windows of the compounds. In general the number of ions should not be greater than 20. The dwell time is important parameter and should be close for each ion. For GC capillary column analysis a dwell time should not be shorter than 20 ms, while a sum of a dwell in each retention time windows should not be greater than 500 ms. An example of conditions that can be used along with dwell times are shown in Table A1.2.

Table A.1.2: Example of operational conditions for the GC-MS analysis of parent and alkylated PAHs.

Group N°	Retention time (min)	Dwell time (ms)	Ions in group (AMU)					
1	8.00	100	128	136	142			
2	21.00	100	152	156	160			
3	23.70	100	154	164	168	170		
4	26.80	80	166	176	180	182	184	
5	31.60	80	178	184	188	194	196	198
6	35.30	100	192	198				
7	36.60	100	206	212				
8	39.40	80	202	206	212	216	220	226
9	44.65	100	216	220				
10	45.30	100	226	228	230	234	240	
11	48.58	90	242	248				
12	52.00	100	252	256	264	266		
13	59.00	100	266	276	278	288
